sage: P.dlxcpp_has_unique_completion()
True
```

dumps()

Since the latin square class doesn't hold any other private variables we just call dumps on self.square:

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2) == loads(dumps(back_circulant(2)))
True
```

filled_cells_map()

Number the filled cells of self with integers from {1, 2, 3, ...}

INPUT:

- `self` - Partial latin square self (empty cells have negative values)

OUTPUT: A dictionary cells_map where cells_map[(i,j)] = m means that (i,j) is the m-th filled cell in P, while cells_map[m] = (i,j).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1.filled_cells_map()
{1: (0, 0),
 2: (0, 2),
 3: (0, 3),
 4: (1, 1),
 5: (1, 2),
 6: (1, 3),
 7: (2, 0),
 8: (2, 1),
 9: (2, 2),
 10: (3, 0),
 11: (3, 1),
 12: (3, 3),
 (0, 0): 1,
 (0, 2): 2,
```

```
 (0, 3): 3,
 (1, 1): 4,
 (1, 2): 5,
 (1, 3): 6,
 (2, 0): 7,
 (2, 1): 8,
 (2, 2): 9,
 (3, 0): 10,
 (3, 1): 11,
 (3, 3): 12}
```

find_disjoint_mates(*nr_to_find=None*, *allow_subtrade=False*)

> **Warning:** If allow_subtrade is `True` then we may return a partial latin square that is *not* disjoint to `self`. In that case, use bitrade(P, Q) to get an actual bitrade.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: g = B.find_disjoint_mates(allow_subtrade = True)
sage: B1 = next(g)
sage: B0, B1 = bitrade(B, B1)
sage: assert is_bitrade(B0, B1)
sage: print B0, "\n,\n", B1
[-1  1  2 -1]
[-1  2 -1  0]
[-1 -1 -1 -1]
[-1  0  1  2]
,
[-1  2  1 -1]
[-1  0 -1  2]
[-1 -1 -1 -1]
[-1  1  2  0]
```

gcs()

A greedy critical set of a latin square self is found by successively removing elements in a row-wise (bottom-up) manner, checking for unique completion at each step.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: A = elementary_abelian_2group(3)
sage: G = A.gcs()
sage: A
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
sage: G
[ 0  1  2  3  4  5  6 -1]
[ 1  0  3  2  5  4 -1 -1]
[ 2  3  0  1  6 -1  4 -1]
[ 3  2  1  0 -1 -1 -1 -1]
[ 4  5  6 -1  0  1  2 -1]
```

```
[ 5  4 -1 -1  1  0 -1 -1]
[ 6 -1  4 -1  2 -1  0 -1]
[-1 -1 -1 -1 -1 -1 -1 -1]
```

is_completable()

Returns True if the partial latin square can be completed to a latin square.

EXAMPLES:

The following partial latin square has no completion because there is nowhere that we can place the symbol 0 in the third row:

```
sage: B = LatinSquare(3)

sage: B[0, 0] = 0
sage: B[1, 1] = 0
sage: B[2, 2] = 1

sage: B
[ 0 -1 -1]
[-1  0 -1]
[-1 -1  1]

sage: B.is_completable()
False

sage: B[2, 2] = 0
sage: B.is_completable()
True
```

is_empty_column(c)

Checks if column c of the partial latin square self is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_column(0)
False
sage: L[0,0] = L[1,0] = L[2,0] = L[3,0] = -1
sage: L.is_empty_column(0)
True
```

is_empty_row(r)

Checks if row r of the partial latin square self is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_row(0)
False
sage: L[0,0] = L[0,1] = L[0,2] = L[0,3] = -1
sage: L.is_empty_row(0)
True
```

is_latin_square()

self is a latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears exactly once in each row, and exactly once in each column.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(4).is_latin_square()
True

sage: forward_circulant(7).is_latin_square()
True
```

is_partial_latin_square()

self is a partial latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears at most once in each row, and at most once in each column.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(4).is_partial_latin_square()
True
sage: back_circulant(3).gcs().is_partial_latin_square()
True
sage: back_circulant(6).is_partial_latin_square()
True
```

is_uniquely_completable()

Returns True if the partial latin square self has exactly one completion to a latin square. This is just a wrapper for the current best-known algorithm, Dancing Links by Knuth. See dancing_links.spyx

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(4).gcs().is_uniquely_completable()
True

sage: G = elementary_abelian_2group(3).gcs()
sage: G.is_uniquely_completable()
True

sage: G[0, 0] = -1
sage: G.is_uniquely_completable()
False
```

latex()

Returns LaTeX code for the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: print back_circulant(3).latex()
\begin{array}{|c|c|c|}\hline 0 & 1 & 2\\\hline 1 & 2 & 0\\\hline 2 & 0 & 1\\\hline\end{array
```

list()

Convert the latin square into a list, in a row-wise manner.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

ncols()

Number of columns in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).ncols()
3
```

nr_distinct_symbols()

Returns the number of distinct symbols in the partial latin square self.

EXAMPLE:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5).nr_distinct_symbols()
5
sage: L = LatinSquare(10)
sage: L.nr_distinct_symbols()
0
sage: L[0, 0] = 0
sage: L[0, 1] = 1
sage: L.nr_distinct_symbols()
2
```

nr_filled_cells()

Returns the number of filled cells (i.e. cells with a positive value) in the partial latin square self.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(matrix([[0, -1], [-1, 0]])).nr_filled_cells()
2
```

nrows()

Number of rows in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).nrows()
3
```

permissable_values(*r*, *c*)

Find all values that do not appear in row r and column c of the latin square self. If self[r, c] is filled then we return the empty list.

INPUT:

- `self` - LatinSquare
- `r` - int; row of the latin square
- `c` - int; column of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(5)
sage: L[0, 0] = -1
sage: L.permissable_values(0, 0)
[0]
```

random_empty_cell()

Find an empty cell of self, uniformly at random.

INPUT:

- `self` - LatinSquare

OUTPUT:

- `[r, c]` - cell such that self[r, c] is empty, or returns None if self is a (full) latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = back_circulant(2)
sage: P[1,1] = -1
sage: P.random_empty_cell()
[1, 1]
```

row(*x*)

Returns row x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).row(0)
(0, 1, 2)
```

set_immutable()

A latin square is immutable if the underlying matrix is immutable.

EXAMPLES:

```
sage: L = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: L.set_immutable()
sage: {L : 0}   # this would fail without set_immutable()
{[0 1]
[2 3]: 0}
```

top_left_empty_cell()

Returns the least [r, c] such that self[r, c] is an empty cell. If all cells are filled then we return None.

INPUT:

- `self` - LatinSquare

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B[3, 4] = -1
sage: B.top_left_empty_cell()
[3, 4]
```

vals_in_col(*c*)

Returns a dictionary with key e if and only if column c of self has the symbol e.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_col(0)
{0: True, 1: True, 2: True}
```

vals_in_row(*r*)

Returns a dictionary with key e if and only if row r of self has the symbol e.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_row(0)
{0: True, 1: True, 2: True}
```

sage.combinat.matrices.latin.**LatinSquare_generator**(*L_start*, *check_assertions=False*)

Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square. This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the StopIteration exception, so it provides an infinite sequence of latin squares.

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

```
sage: from sage.combinat.matrices.latin import *
sage: g = LatinSquare_generator(back_circulant(4))
sage: next(g).is_latin_square()
True
```

REFERENCES:

sage.combinat.matrices.latin.**alternating_group_bitrade_generators**(*m*)

Construct generators a, b, c for the alternating group on 3m+1 points, such that a*b*c = 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
sage: a*b*c
()

sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

sage.combinat.matrices.latin.**back_circulant**(*n*)

The back-circulant latin square of order n is the Cayley table for (Z_n, +), the integers under addition modulo n.

INPUT:

- n - int; order of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5)
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
```

```
[3 4 0 1 2]
[4 0 1 2 3]
```

sage.combinat.matrices.latin.**beta1**(*rce*, *T1*, *T2*)

Find the unique (x, c, e) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` - tuple (or list) (r, c, e) in T1
- `T1, T2` - latin bitrade

OUTPUT: (x, c, e) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta1([0, 0, 0], T1, T2)
(1, 0, 0)
```

sage.combinat.matrices.latin.**beta2**(*rce*, *T1*, *T2*)

Find the unique (r, x, e) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` - tuple (or list) (r, c, e) in T1
- `T1, T2` - latin bitrade

OUTPUT:

- (r, x, e) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta2([0, 0, 0], T1, T2)
(0, 1, 0)
```

sage.combinat.matrices.latin.**beta3**(*rce*, *T1*, *T2*)

Find the unique (r, c, x) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` - tuple (or list) (r, c, e) in T1
- `T1, T2` - latin bitrade

OUTPUT:

•(r, c, x) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta3([0, 0, 0], T1, T2)
(0, 0, 4)
```

sage.combinat.matrices.latin.**bitrade**(*T1*, *T2*)

Form the bitrade (Q1, Q2) from (T1, T2) by setting empty the cells (r, c) such that T1[r, c] == T2[r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B1 = back_circulant(5)
sage: alpha = isotopism((0,1,2,3,4))
sage: beta  = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B2 = B1.apply_isotopism(alpha, beta, gamma)
sage: T1, T2 = bitrade(B1, B2)
sage: T1
[ 0  1 -1  3  4]
[ 1 -1 -1  4  0]
[ 2 -1  4  0  1]
[ 3  4  0  1  2]
[ 4  0  1  2  3]
sage: T2
[ 3  4 -1  0  1]
[ 0 -1 -1  1  4]
[ 1 -1  0  4  2]
[ 4  0  1  2  3]
[ 2  1  4  3  0]
```

sage.combinat.matrices.latin.**bitrade_from_group**(*a*, *b*, *c*, *G*)

Given group elements a, b, c in G such that abc = 1 and the subgroups a, b, c intersect (pairwise) only in the identity, construct a bitrade (T1, T2) where rows, columns, and symbols correspond to cosets of a, b, and c, respectively.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

sage.combinat.matrices.latin.**cells_map_as_square**(*cells_map*, *n*)
Returns a LatinSquare with cells numbered from 1, 2, ... to given the dictionary cells_map.

Note: The value n should be the maximum of the number of rows and columns of the original partial latin square

---

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
```

There are 12 filled cells in T:

```
sage: cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[ 1 -1  2  3]
[-1  4  5  6]
[ 7  8  9 -1]
[10 11 -1 12]
```

sage.combinat.matrices.latin.**check_bitrade_generators**(*a*, *b*, *c*)
Three group elements a, b, c will generate a bitrade if a*b*c = 1 and the subgroups a, b, c intersect (pairwise) in just the identity.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(3)
sage: check_bitrade_generators(a, b, c)
True
sage: check_bitrade_generators(a, b, gap('()'))
False
```

sage.combinat.matrices.latin.**coin**()
Simulates a fair coin (returns True or False) using ZZ.random_element(2).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: x = coin()
sage: x == 0 or x == 1
True
```

sage.combinat.matrices.latin.**column_containing_sym**(*L*, *r*, *x*)
Given an improper latin square L with L[r, c1] = L[r, c2] = x, return c1 or c2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(1, 0, 2, 3), (0, 2, 3, 0), (2, 3, 0, 1), (3, 0, 1, 2)])
sage: L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
```

```
sage: c = column_containing_sym(L, 1, 0)
sage: c == 0 or c == 3
True
```

sage.combinat.matrices.latin.**direct_product**(*L1*, *L2*, *L3*, *L4*)

The 'direct product' of four latin squares L1, L2, L3, L4 of order n is the latin square of order 2n consisting of

```
-----------
| L1 | L2 |
-----------
| L3 | L4 |
-----------
```

where the subsquares L2 and L3 have entries offset by n.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: direct_product(back_circulant(4), back_circulant(4), elementary_abelian_2group(2), element
[0 1 2 3 4 5 6 7]
[1 2 3 0 5 6 7 4]
[2 3 0 1 6 7 4 5]
[3 0 1 2 7 4 5 6]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

sage.combinat.matrices.latin.**dlxcpp_find_completions**(*P*, *nr_to_find=None*)

Returns a list of all latin squares L of the same order as P such that P is contained in L. The optional parameter nr_to_find limits the number of latin squares that are found.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_find_completions(LatinSquare(2))
[[0 1]
[1 0], [1 0]
[0 1]]

sage: dlxcpp_find_completions(LatinSquare(2), 1)
[[0 1]
[1 0]]
```

sage.combinat.matrices.latin.**dlxcpp_rows_and_map**(*P*)

Internal function for dlxcpp_find_completions. Given a partial latin square P we construct a list of rows of a 0-1 matrix M such that an exact cover of M corresponds to a completion of P to a latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_rows_and_map(LatinSquare(2))
([[0, 4, 8],
  [1, 5, 8],
  [2, 4, 9],
  [3, 5, 9],
  [0, 6, 10],
  [1, 7, 10],
  [2, 6, 11],
  [3, 7, 11]],
 {(0, 4, 8): (0, 0, 0),
```

```
(0, 6, 10): (1, 0, 0),
(1, 5, 8): (0, 0, 1),
(1, 7, 10): (1, 0, 1),
(2, 4, 9): (0, 1, 0),
(2, 6, 11): (1, 1, 0),
(3, 5, 9): (0, 1, 1),
(3, 7, 11): (1, 1, 1)})
```

sage.combinat.matrices.latin.**elementary_abelian_2group**(*s*)

Returns the latin square based on the Cayley table for the elementary abelian 2-group of order 2s.

INPUT:

- s - int; order of the latin square will be 2s.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(3)
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

sage.combinat.matrices.latin.**forward_circulant**(*n*)

The forward-circulant latin square of order n is the Cayley table for the operation r + c = (n-c+r) mod n.

INPUT:

- n - int; order of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: forward_circulant(5)
[0 4 3 2 1]
[1 0 4 3 2]
[2 1 0 4 3]
[3 2 1 0 4]
[4 3 2 1 0]
```

sage.combinat.matrices.latin.**genus**(*T1*, *T2*)

Returns the genus of hypermap embedding associated with the bitrade (T1, T2). Informally, we compute the [tau_1, tau_2, tau_3] permutation representation of the bitrade. Each cycle of tau_1, tau_2, and tau_3 gives a rotation scheme for a black, white, and star vertex (respectively). The genus then comes from Euler's formula. For more details see Carlo Hamalainen: Partitioning 3-homogeneous latin bitrades. To appear in Geometriae Dedicata, available at http://arxiv.org/abs/0710.0938

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
1
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
```

```
sage: genus(T1, T2)
3
```

sage.combinat.matrices.latin.**group_to_LatinSquare**(*G*)

Construct a latin square on the symbols [0, 1, ..., n-1] for a group with an n by n Cayley table.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: group_to_LatinSquare(DihedralGroup(2))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]

sage: G = gap.Group(PermutationGroupElement((1,2,3)))
sage: group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

sage.combinat.matrices.latin.**is_bitrade**(*T1*, *T2*)

Combinatorially, a pair (T1, T2) of partial latin squares is a bitrade if they are disjoint, have the same shape, and have row and column balance. For definitions of each of these terms see the relevant function in this file.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
```

sage.combinat.matrices.latin.**is_disjoint**(*T1*, *T2*)

The partial latin squares T1 and T2 are disjoint if T1[r, c] != T2[r, c] or T1[r, c] == T2[r, c] == -1 for each cell [r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import is_disjoint, back_circulant, isotopism
sage: is_disjoint(back_circulant(2), back_circulant(2))
False

sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_disjoint(T1, T2)
True
```

sage.combinat.matrices.latin.**is_primary_bitrade**(*a*, *b*, *c*, *G*)

A bitrade generated from elements a, b, c is primary if a, b, c = G.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = p3_group_bitrade_generators(5)
sage: is_primary_bitrade(a, b, c, G)
True
```

sage.combinat.matrices.latin.**is_row_and_col_balanced**(*T1*, *T2*)

Partial latin squares T1 and T2 are balanced if the symbols appearing in row r of T1 are the same as the symbols appearing in row r of T2, for each r, and if the same condition holds on columns.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: T2 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
True
sage: T2 = matrix([[0,3,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
False
```

sage.combinat.matrices.latin.**is_same_shape**(*T1*, *T2*)

Two partial latin squares T1, T2 have the same shape if T1[r, c] = 0 if and only if T2[r, c] = 0.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: is_same_shape(elementary_abelian_2group(2), back_circulant(4))
True
sage: is_same_shape(LatinSquare(5), LatinSquare(5))
True
sage: is_same_shape(forward_circulant(5), LatinSquare(5))
False
```

sage.combinat.matrices.latin.**isotopism**(*p*)

Return a Permutation object that represents an isotopism (for rows, columns or symbols of a partial latin square).

Technically, all this function does is take as input a representation of a permutation of $0, ..., n-1$ and return a `Permutation` object defined on $1, ..., n$.

For a definition of isotopism, see the wikipedia section on isotopism.

INPUT:

According to the type of input (see examples below) :

- an integer n – the function returns the identity on $1, ..., n$.
- a string representing a permutation in disjoint cycles notation, e.g. $(0, 1, 2)(3, 4, 5)$ – the corresponding permutation is returned, shifted by 1 to act on $1, ..., n$.
- list/tuple of tuples – assumes disjoint cycle notation, see previous entry.
- a list of integers – the function adds 1 to each member of the list, and returns the corresponding permutation.
- a `PermutationGroupElement` `p` – returns a permutation describing `p` **without** any shift.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: isotopism(5) # identity on 5 points
[1, 2, 3, 4, 5]
```

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: isotopism(g)
[2, 3, 1, 5, 4]

sage: isotopism([0,3,2,1]) # 0 goes to 0, 1 goes to 3, etc.
[1, 4, 3, 2]

sage: isotopism( (0,1,2) ) # single cycle, presented as a tuple
[2, 3, 1]

sage: x = isotopism( ((0,1,2), (3,4)) ) # tuple of cycles
sage: x
[2, 3, 1, 5, 4]
sage: x.to_cycles()
[(1, 2, 3), (4, 5)]
```

sage.combinat.matrices.latin.**next_conjugate**(*L*)

Permutes L[r, c] = e to the conjugate L[c, e] = r.

We assume that L is an n by n matrix and has values in the range 0, 1, ..., n-1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(6)
sage: L
[0 1 2 3 4 5]
[1 2 3 4 5 0]
[2 3 4 5 0 1]
[3 4 5 0 1 2]
[4 5 0 1 2 3]
[5 0 1 2 3 4]
sage: next_conjugate(L)
[0 1 2 3 4 5]
[5 0 1 2 3 4]
[4 5 0 1 2 3]
[3 4 5 0 1 2]
[2 3 4 5 0 1]
[1 2 3 4 5 0]
sage: L == next_conjugate(next_conjugate(next_conjugate(L)))
True
```

sage.combinat.matrices.latin.**p3_group_bitrade_generators**(*p*)

Generators for a group of order p3 where p is a prime.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: p3_group_bitrade_generators(3)
((2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9), (1,9,2)(3,7,4)(5,8,6), Permutation Group with generators
```

sage.combinat.matrices.latin.**pq_group_bitrade_generators**(*p*, *q*)

Generators for a group of order pq where p and q are primes such that (q % p) == 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: pq_group_bitrade_generators(3,7)
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with generators [(2,3,5)(4,7
```

sage.combinat.matrices.latin.**row_containing_sym**(*L*, *c*, *x*)

Given an improper latin square L with L[r1, c] = L[r2, c] = x, return r1 or r2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(0, 1, 0, 3), (3, 0, 2, 1), (1, 0, 3, 2), (2, 3, 1, 0)])
sage: L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]
sage: c = row_containing_sym(L, 1, 0)
sage: c == 1 or c == 2
True
```

sage.combinat.matrices.latin.**tau1**(*T1*, *T2*, *cells_map*)

The definition of τ_1 is

$$\tau_1 : T1 \to T1$$
$$\tau_1 = \beta_2^{-1}\beta_3$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i^{th} coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t1 = tau1(T1, T2, cells_map)
sage: t1
[2, 3, 4, 5, 1, 7, 8, 9, 10, 6, 12, 13, 14, 15, 11, 17, 18, 19, 20, 16, 22, 23, 24, 25, 21]
sage: t1.to_cycles()
[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20), (21, 22, 23, 24,
```

sage.combinat.matrices.latin.**tau123**(*T1*, *T2*)

Compute the tau_i representation for a bitrade (T1, T2). See the functions tau1, tau2, and tau3 for the mathematical definitions.

OUTPUT:

- (cells_map, t1, t2, t3)

where cells_map is a map to/from the filled cells of T1, and t1, t2, t3 are the tau1, tau2, tau3 permutations.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0  1  3 -1 -1 -1 -1]
[ 1  2  4 -1 -1 -1 -1]
[ 2  3  5 -1 -1 -1 -1]
[ 3  4  6 -1 -1 -1 -1]
```

```
[ 4  5  0 -1 -1 -1 -1]
[ 5  6  1 -1 -1 -1 -1]
[ 6  0  2 -1 -1 -1 -1]
sage: T2
[ 1  3  0 -1 -1 -1 -1]
[ 2  4  1 -1 -1 -1 -1]
[ 3  5  2 -1 -1 -1 -1]
[ 4  6  3 -1 -1 -1 -1]
[ 5  0  4 -1 -1 -1 -1]
[ 6  1  5 -1 -1 -1 -1]
[ 0  2  6 -1 -1 -1 -1]
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: cells_map
{1: (0, 0),
 2: (0, 1),
 3: (0, 2),
 4: (1, 0),
 5: (1, 1),

 (6, 1): 20,
 (6, 2): 21}
sage: cells_map_as_square(cells_map, max(T1.nrows(), T1.ncols()))
[ 1  2  3 -1 -1 -1 -1]
[ 4  5  6 -1 -1 -1 -1]
```

```
[ 7  8  9 -1 -1 -1 -1]
[10 11 12 -1 -1 -1 -1]
[13 14 15 -1 -1 -1 -1]
[16 17 18 -1 -1 -1 -1]
[19 20 21 -1 -1 -1 -1]
sage: t1
[3, 1, 2, 6, 4, 5, 9, 7, 8, 12, 10, 11, 15, 13, 14, 18, 16, 17, 21, 19, 20]
sage: t2
[4, 8, 15, 7, 11, 18, 10, 14, 21, 13, 17, 3, 16, 20, 6, 19, 2, 9, 1, 5, 12]
sage: t3
[20, 18, 10, 2, 21, 13, 5, 3, 16, 8, 6, 19, 11, 9, 1, 14, 12, 4, 17, 15, 7]

sage: t1.to_cycles()
[(1, 3, 2), (4, 6, 5), (7, 9, 8), (10, 12, 11), (13, 15, 14), (16, 18, 17), (19, 21, 20)]
sage: t2.to_cycles()
[(1, 4, 7, 10, 13, 16, 19), (2, 8, 14, 20, 5, 11, 17), (3, 15, 6, 18, 9, 21, 12)]
sage: t3.to_cycles()
[(1, 20, 15), (2, 18, 4), (3, 10, 8), (5, 21, 7), (6, 13, 11), (9, 16, 14), (12, 19, 17)]
```

The product t1*t2*t3 is the identity, i.e. it fixes every point:

```
sage: len((t1*t2*t3).fixed_points()) == T1.nr_filled_cells()
True
```

sage.combinat.matrices.latin.**tau2**(*T1*, *T2*, *cells_map*)

The definition of τ_2 is

$$\tau_2 : T1 \to T1$$
$$\tau_2 = \beta_3^{-1}\beta_1$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i^{th} coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t2 = tau2(T1, T2, cells_map)
sage: t2
[21, 22, 23, 24, 25, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
sage: t2.to_cycles()
[(1, 21, 16, 11, 6), (2, 22, 17, 12, 7), (3, 23, 18, 13, 8), (4, 24, 19, 14, 9), (5, 25, 20, 15,
```

sage.combinat.matrices.latin.**tau3**(*T1*, *T2*, *cells_map*)

The definition of τ_3 is

$$\tau_3 : T1 \to T1$$
$$\tau_3 = \beta_1^{-1}\beta_2$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i^{th} coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t3 = tau3(T1, T2, cells_map)
sage: t3
[10, 6, 7, 8, 9, 15, 11, 12, 13, 14, 20, 16, 17, 18, 19, 25, 21, 22, 23, 24, 5, 1, 2, 3, 4]
sage: t3.to_cycles()
[(1, 10, 14, 18, 22), (2, 6, 15, 19, 23), (3, 7, 11, 20, 24), (4, 8, 12, 16, 25), (5, 9, 13, 17,
```

sage.combinat.matrices.latin.**tau_to_bitrade**(*t1*, *t2*, *t3*)

Given permutations t1, t2, t3 that represent a latin bitrade, convert them to an explicit latin bitrade (T1, T2). The result is unique up to isotopism.

EXAMPLE:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: _, t1, t2, t3 = tau123(T1, T2)
sage: U1, U2 = tau_to_bitrade(t1, t2, t3)
sage: assert is_bitrade(U1, U2)
sage: U1
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: U2
[4 0 1 2 3]
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
```

5.1.123 Miscellaneous

class sage.combinat.misc.**DoublyLinkedList**(*l*)

A doubly linked list class that provides constant time hiding and unhiding of entries.

Note that this list's indexing is 1-based.

EXAMPLES:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3]); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(1); dll
Doubly linked list of [1, 2, 3]: [2, 3]
sage: dll.unhide(1); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

```
sage: dll.hide(2); dll
Doubly linked list of [1, 2, 3]: [1, 3]
sage: dll.unhide(2); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

head()

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.head()
1
sage: dll.hide(1)
sage: dll.head()
2
```

hide(*i*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.hide(1)
sage: list(dll)
[2, 3]
```

next(*j*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.next(1)
2
sage: dll.hide(2)
sage: dll.next(1)
3
```

prev(*j*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.prev(3)
2
sage: dll.hide(2)
sage: dll.prev(3)
1
```

unhide(*i*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.hide(1); dll.unhide(1)
sage: list(dll)
[1, 2, 3]
```

class sage.combinat.misc.**IterableFunctionCall**(*f*, **args*, ***kwargs*)

This class wraps functions with a yield statement (generators) by an object that can be iterated over. For example,

EXAMPLES:

```
sage: def f(): yield 'a'; yield 'b'
```

This does not work:

```
sage: for z in f: print z
Traceback (most recent call last):
...
TypeError: 'function' object is not iterable
```

Use IterableFunctionCall if you want something like the above to work:

```
sage: from sage.combinat.misc import IterableFunctionCall
sage: g = IterableFunctionCall(f)
sage: for z in g: print z
a
b
```

If your function takes arguments, just put them after the function name. You needn't enclose them in a tuple or anything, just put them there:

```
sage: def f(n, m): yield 'a' * n; yield 'b' * m; yield 'foo'
sage: g = IterableFunctionCall(f, 2, 3)
sage: for z in g: print z
aa
bbb
foo
```

sage.combinat.misc.**check_integer_list_constraints**(*l*, ***kwargs*)

EXAMPLES:

```
sage: from sage.combinat.misc import check_integer_list_constraints
sage: cilc = check_integer_list_constraints
sage: l = [[2,1,3],[1,2],[3,3],[4,1,1]]
sage: cilc(l, min_part=2)
[[3, 3]]
sage: cilc(l, max_part=2)
[[1, 2]]
sage: cilc(l, length=2)
[[1, 2], [3, 3]]
sage: cilc(l, max_length=2)
[[1, 2], [3, 3]]
sage: cilc(l, min_length=3)
[[2, 1, 3], [4, 1, 1]]
sage: cilc(l, max_slope=0)
[[3, 3], [4, 1, 1]]
sage: cilc(l, min_slope=1)
[[1, 2]]
sage: cilc(l, outer=[2,2])
[[1, 2]]
sage: cilc(l, inner=[2,2])
[[3, 3]]

sage: cilc([1,2,3], length=3, singleton=True)
[1, 2, 3]
sage: cilc([1,2,3], length=2, singleton=True) is None
True
```

sage.combinat.misc.**umbral_operation**(*poly*)

Returns the umbral operation $\downarrow$ applied to poly.

The umbral operation replaces each instance of $x_i^{a_i}$ with $x_i * (x_i - 1) * \cdots * (x_i - a_i + 1)$.

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 2, 'x')
sage: x = P.gens()
sage: from sage.combinat.misc import umbral_operation
sage: umbral_operation(x[0]^3) == x[0]*(x[0]-1)*(x[0]-2)
True
sage: umbral_operation(x[0]*x[1])
x0*x1
sage: umbral_operation(x[0]+x[1])
x0 + x1
sage: umbral_operation(x[0]^2*x[1]^2) == x[0]*(x[0]-1)*x[1]*(x[1]-1)
True
```

5.1.124 Low-level multichoose

class sage.combinat.multichoose_nk.**MultichooseNK**(n, k)

Bases: sage.combinat.combinat.CombinatorialClass

TESTS:

```
sage: a = MultichooseNK(3,2)
sage: a == loads(dumps(a))
True
```

cardinality()

Returns the number of multichoices of k things from a list of n things.

EXAMPLES:

```
sage: MultichooseNK(3,2).cardinality()
6
```

random_element()

Returns a random multichoice of k things from range(n).

EXAMPLES:

```
sage: MultichooseNK(5,2).random_element()
[0, 2]
sage: MultichooseNK(5,2).random_element()
[0, 1]
```

5.1.125 Non-Commutative Symmetric Functions and Quasi-Symmetric Functions

- *Introduction to Quasisymmetric Functions*
- *Non-Commutative Symmetric Functions (NCSF)*
- *Quasi-Symmetric Functions (QSym)*
- *Generic code for bases*

5.1.126 Features that are imported by default in the interpreter namespace

5.1.127 Common combinatorial tools

REFERENCES:

sage.combinat.ncsf_qsym.combinatorics.**coeff_dab**(I, J)

Return the number of standard composition tableaux of shape I with descent composition J.

INPUT:

- I, J – compositions

OUTPUT:

- An integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
sage: coeff_dab(Composition([2,1]),Composition([2,1]))
1
sage: coeff_dab(Composition([1,1,2]),Composition([1,2,1]))
0
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_ell**(J, I)

Returns the coefficient $\ell_{J,I}$ as defined in [NCSF].

INPUT:

- J – a composition
- I – a composition refining J

OUTPUT:

- integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_ell
sage: coeff_ell(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_ell(Composition([2,1]), Composition([3]))
2
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_lp**(J, I)

Returns the coefficient $lp_{J,I}$ as defined in [NCSF].

INPUT:

- J – a composition
- I – a composition refining J

OUTPUT:

- integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_lp
sage: coeff_lp(Composition([1,1,1]), Composition([2,1]))
1
sage: coeff_lp(Composition([2,1]), Composition([3]))
1
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_pi**(*J*, *I*)

Returns the coefficient $\pi_{J,I}$ as defined in [NCSF].

INPUT:

- J – a composition
- I – a composition refining J

OUTPUT:

- integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_pi
sage: coeff_pi(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_pi(Composition([2,1]), Composition([3]))
6
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_sp**(*J*, *I*)

Returns the coefficient $sp_{J,I}$ as defined in [NCSF].

INPUT:

- J – a composition
- I – a composition refining J

OUTPUT:

- integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_sp
sage: coeff_sp(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_sp(Composition([2,1]), Composition([3]))
4
```

sage.combinat.ncsf_qsym.combinatorics.**compositions_order**(*n*)

Return the compositions of n ordered as defined in [QSCHUR].

Let $S(\gamma)$ return the composition γ after sorting. For compositions α and β, we order $\alpha \rhd \beta$ if

1. $S(\alpha) > S(\beta)$ lexicographically, or
2. $S(\alpha) = S(\beta)$ and $\alpha > \beta$ lexicographically.

INPUT:

- n – a positive integer

OUTPUT:

- A list of the compositions of n sorted into decreasing order by $\rhd$

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import compositions_order
sage: compositions_order(3)
[[3], [2, 1], [1, 2], [1, 1, 1]]
```

```
sage: compositions_order(4)
[[4], [3, 1], [1, 3], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

sage.combinat.ncsf_qsym.combinatorics.**m_to_s_stat**(*R*, *I*, *K*)

Return the coefficient of the complete non-commutative symmetric function S^K in the expansion of the monomial non-commutative symmetric function M^I with respect to the complete basis over the ring R. This is the coefficient in formula (36) of Tevlin's paper [Tev2007].

INPUT:

- `R` – A ring, supposed to be a **Q**-algebra
- `I`, `K` – compositions

OUTPUT:

- The coefficient of S^K in the expansion of M^I in the complete basis of the non-commutative symmetric functions over `R`.

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import m_to_s_stat
sage: m_to_s_stat(QQ, Composition([2,1]), Composition([1,1,1]))
-1
sage: m_to_s_stat(QQ, Composition([3]), Composition([1,2]))
-2
sage: m_to_s_stat(QQ, Composition([2,1,2]), Composition([2,1,2]))
8/3
```

sage.combinat.ncsf_qsym.combinatorics.**number_of_SSRCT**(*content_comp*, *shape_comp*)

The number of semi-standard reverse composition tableaux.

The dual quasisymmetric-Schur functions satisfy a left Pieri rule where $S_n dQS_\gamma$ is a sum over dual quasisymmetric-Schur functions indexed by compositions which contain the composition γ. The definition of an SSRCT comes from this rule. The number of SSRCT of content β and shape α is equal to the number of SSRCT of content $(\beta_2, \ldots, \beta_\ell)$ and shape γ where dQS_α appears in the expansion of $S_{\beta_1} dQS_\gamma$.

In sage the recording tableau for these objects are called `CompositionTableaux`.

INPUT:

- `content_comp`, `shape_comp` – compositions

OUTPUT:

- An integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
sage: number_of_SSRCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_SSRCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_SSRCT(Composition([1,1,2,2]), Composition([3,3]))
2
sage: all(CompositionTableaux(be).cardinality()
....:     == sum(number_of_SSRCT(al,be)*binomial(4,len(al))
....:            for al in Compositions(4))
....:     for be in Compositions(4))
True
```

sage.combinat.ncsf_qsym.combinatorics.**number_of_fCT**(*content_comp*, *shape_comp*)
Return the number of Immaculate tableaux of shape `shape_comp` and content `content_comp`.

See [BBSSZ2012], Definition 3.9, for the notion of an immaculate tableau.

INPUT:

- `content_comp`, `shape_comp` – compositions

OUTPUT:

- An integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
sage: number_of_fCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_fCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_fCT(Composition([1,1,3,1]), Composition([2,1,3]))
2
```

5.1.128 Generic code for bases

This is a collection of code that is shared by bases of noncommutative symmetric functions and quasisymmetric functions.

AUTHORS:

- Jason Bandlow
- Franco Saliola
- Chris Berg

class sage.combinat.ncsf_qsym.generic_basis_code.**AlgebraMorphism**(*domain*, *on_generators*, *position=0*, *codomain=None*, *category=None*, *anti=False*)
Bases: sage.modules.with_basis.morphism.ModuleMorphismByLinearity

A class for algebra morphism defined on a free algebra from the image of the generators

class sage.combinat.ncsf_qsym.generic_basis_code.**BasesOfQSymOrNCSF**(*parent_with_realization*)
Bases: sage.categories.realizations.Category_realization_of_parent

TESTS:

```
sage: from sage.categories.realizations import Category_realization_of_parent
sage: A = Sets().WithRealizations().example(); A
The subset algebra of {1, 2, 3} over Rational Field
sage: C = A.Realizations(); C
Category of realizations of The subset algebra of {1, 2, 3} over Rational Field
sage: isinstance(C, Category_realization_of_parent)
True
sage: C.parent_with_realization
The subset algebra of {1, 2, 3} over Rational Field
sage: TestSuite(C).run(skip=["_test_category_over_bases"])
```

Todo

Fix the failing test by making `C` a singleton category. This will require some fiddling with the assertion in `Category_singleton.__classcall__()`

class ElementMethods

degree()

The maximum of the degrees of the homogeneous summands.

See also:

`homogeneous_degree()`

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: (x, y) = (S[2], S[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6

sage: F = QuasiSymmetricFunctions(QQ).F()
sage: (x, y) = (F[2], F[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6
```

TESTS:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.zero().degree()
Traceback (most recent call last):
...
ValueError: the zero element does not have a well-defined degree
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.zero().degree()
Traceback (most recent call last):
...
ValueError: the zero element does not have a well-defined degree
```

degree_negation()

Return the image of `self` under the degree negation automorphism of the parent of `self`.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

Calling `degree_negation(self)` is equivalent to calling `self.parent().degree_negation(self)`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[[]]
sage: f.degree_negation()
```

```
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: f = -3*dI[2,1] + 4*dI[2] + 2*dI[1]
sage: f.degree_negation()
-2*dI[1] + 4*dI[2] + 3*dI[2, 1]
```

TESTS:

The zero element behaves well:

```
sage: a = S.zero().degree_negation(); a
0
sage: parent(a)
Non-Commutative Symmetric Functions over the Integer Ring in the Complete basis
```

Todo

Generalize this to all graded vector spaces?

duality_pairing(*y*)

The duality pairing between elements of $NSym$ and elements of $QSym$.

The complete basis is dual to the monomial basis with respect to this pairing.

INPUT:

- `y` – an element of the dual Hopf algebra of `self`

OUTPUT:

- The result of pairing `self` with `y`.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R[1,1,2].duality_pairing(F[1,1,2])
1
sage: R[1,2,1].duality_pairing(F[1,1,2])
0

sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L[1,2].duality_pairing(F[1,2])
0
sage: L[1,1,1].duality_pairing(F[1,2])
1
```

skew_by(*y*, *side='left'*)

The operation which is dual to multiplication by `y`, where `y` is an element of the dual space of `self`.

This is calculated through the coproduct of `self` and the expansion of `y` in the dual basis.

INPUT:

- `y` – an element of the dual Hopf algebra of `self`
- `side` – (Default='left') Either 'left' or 'right'

OUTPUT:

- The result of skewing `self` by `y`, on the side `side`

EXAMPLES:

Skewing an element of NCSF by an element of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
```

```
sage: R([2,2,2]).skew_by(F[1,1])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 2*R[2, 2] + R[3, 1] + R[4]
sage: R([2,2,2]).skew_by(F[2])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 3*R[2, 2] + R[3, 1] + R[4]
```

Skewing an element of QSym by an element of NCSF:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F[3,2].skew_by(R[1,1])
0
sage: F[3,2].skew_by(R[1,1], side='right')
0
sage: F[3,2].skew_by(S[1,1,1], side='right')
F[2]
sage: F[3,2].skew_by(S[1,2], side='right')
F[2]
sage: F[3,2].skew_by(S[2,1], side='right')
0
sage: F[3,2].skew_by(S[1,1,1])
F[2]
sage: F[3,2].skew_by(S[1,1])
F[1, 2]
sage: F[3,2].skew_by(S[1])
F[2, 2]
```

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M[3,2].skew_by(S[2])
0
sage: M[3,2].skew_by(S[2], side='right')
M[3]
sage: M[3,2].skew_by(S[3])
M[2]
sage: M[3,2].skew_by(S[3], side='right')
0
```

class BasesOfQSymOrNCSF.**ParentMethods**

alternating_sum_of_compositions(*n*)

Alternating sum over compositions of n.

Note that this differs from the method alternating_sum_of_finer_compositions() because the coefficient of the composition 1^n is positive. This method is used in the expansion of the elementary generators into the complete generators and vice versa.

INPUT:

- n – a positive integer

OUTPUT:

- The expansion of the complete generator indexed by n into the elementary basis.

EXAMPLES:

```
sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: L.alternating_sum_of_compositions(0)
L[]
sage: L.alternating_sum_of_compositions(1)
L[1]
sage: L.alternating_sum_of_compositions(2)
```

```
L[1, 1] - L[2]
sage: L.alternating_sum_of_compositions(3)
L[1, 1, 1] - L[1, 2] - L[2, 1] + L[3]
sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.alternating_sum_of_compositions(3)
S[1, 1, 1] - S[1, 2] - S[2, 1] + S[3]
```

alternating_sum_of_fatter_compositions(*composition*)

Return the alternating sum of fatter compositions in a basis of the non-commutative symmetric functions.

INPUT:

- `composition` – a composition

OUTPUT:

- The alternating sum of the compositions fatter than `composition`, in the basis `self`. The alternation is upon the length of the compositions, and is normalized so that `composition` has coefficient 1.

EXAMPLES:

```
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_fatter_compositions(Composition([2,2,1]))
L[2, 2, 1] - L[2, 3] - L[4, 1] + L[5]
sage: elementary.alternating_sum_of_fatter_compositions(Composition([1,2]))
L[1, 2] - L[3]
```

TESTS:

```
sage: complete = NonCommutativeSymmetricFunctions(ZZ).complete()
sage: I = Composition([1,1])
sage: x = complete.alternating_sum_of_fatter_compositions(I)
sage: [c.parent() for c in x.coefficients()]
[Integer Ring, Integer Ring]
```

alternating_sum_of_finer_compositions(*composition*, *conjugate=False*)

Return the alternating sum of finer compositions in a basis of the non-commutative symmetric functions.

INPUT:

- `composition` – a composition
- `conjugate` – (default: `False`) a boolean

OUTPUT:

- The alternating sum of the compositions finer than `composition`, in the basis `self`. The alternation is upon the length of the compositions, and is normalized so that `composition` has coefficient 1. If the variable `conjugate` is set to `True`, then the conjugate of `composition` is used instead of `composition`.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_finer_compositions(Composition([2,2,1]))
L[1, 1, 1, 1, 1] - L[1, 1, 2, 1] - L[2, 1, 1, 1] + L[2, 2, 1]
sage: elementary.alternating_sum_of_finer_compositions(Composition([1,2]))
-L[1, 1, 1] + L[1, 2]
```

TESTS:

```
sage: complete = NonCommutativeSymmetricFunctions(ZZ).complete()
sage: I = Composition([2])
sage: x = complete.alternating_sum_of_finer_compositions(I)
sage: [c.parent() for c in x.coefficients()]
```

```
[Integer Ring, Integer Ring]
```

counit_on_basis(*I*)

The counit is defined by sending all elements of positive degree to zero.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.counit_on_basis([1,3])
0
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.counit_on_basis([1,3])
0
```

TESTS:

```
sage: S.counit_on_basis([])
1
sage: S.counit_on_basis(Composition([]))
1
sage: M.counit_on_basis([])
1
sage: M.counit_on_basis(Composition([]))
1
```

degree_negation(*element*)

Return the image of `element` under the degree negation automorphism of `self`.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

INPUT:

- `element` – element of `self`

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[[]]
sage: S.degree_negation(f)
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: f = -3*dI[2,1] + 4*dI[2] + 2*dI[1]
sage: dI.degree_negation(f)
-2*dI[1] + 4*dI[2] + 3*dI[2, 1]
```

TESTS:

Using `degree_negation()` on an element of a different basis works correctly:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: Phi = NSym.Phi()
sage: S.degree_negation(Phi[2])
-S[1, 1] + 2*S[2]
sage: S.degree_negation(Phi[3])
-S[1, 1, 1] + 3/2*S[1, 2] + 3/2*S[2, 1] - 3*S[3]
sage: Phi.degree_negation(S[3])
-1/6*Phi[1, 1, 1] - 1/4*Phi[1, 2] - 1/4*Phi[2, 1] - 1/3*Phi[3]
```

The zero element behaves well:

```
sage: a = Phi.degree_negation(S.zero()); a
0
sage: parent(a)
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
```

Todo

Generalize this to all graded vector spaces?

---

degree_on_basis(*I*)

Return the degree of the basis element indexed by I.

INPUT:

- `I` – a composition

OUTPUT:

- The degree of the non-commutative symmetric function basis element of `self` indexed by `I`. By definition, this is the size of the composition `I`.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.degree_on_basis(Composition([2,3]))
5
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M.degree_on_basis(Composition([3,2]))
5
sage: M.degree_on_basis(Composition([]))
0
```

duality_pairing(*x*, *y*)

The duality pairing between elements of $NSym$ and elements of $QSym$.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

INPUT:

- `x` – an element of `self`
- `y` – an element in the dual basis of `self`

OUTPUT:

- The result of pairing the function `x` from `self` with the function `y` from the dual basis of `self`

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing(R[1,1,2], F[1,1,2])
1
sage: R.duality_pairing(R[1,2,1], F[1,1,2])
0
sage: F.duality_pairing(F[1,2,1], R[1,1,2])
0

sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing(S[1,1,2], M[1,1,2])
1
sage: S.duality_pairing(S[1,2,1], M[1,1,2])
0
sage: M.duality_pairing(M[1,1,2], S[1,1,2])
1
sage: M.duality_pairing(M[1,2,1], S[1,1,2])
0
```

```
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing(S[1,2], F[1,1,1])
0
sage: S.duality_pairing(S[1,1,1,1], F[4])
1
```

TESTS:

The result has the right parent even if the sum is empty:

```
sage: x = S.duality_pairing(S.zero(), F.zero()); x
0
sage: parent(x)
Rational Field
```

duality_pairing_by_coercion(*x*, *y*)

The duality pairing between elements of NSym and elements of QSym.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

INPUT:

- `x` – an element of `self`
- `y` – an element in the dual basis of `self`

OUTPUT:

- The result of pairing the function `x` from `self` with the function `y` from the dual basis of `self`

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L.duality_pairing_by_coercion(L[1,2], F[1,2])
0
sage: F.duality_pairing_by_coercion(F[1,2], L[1,2])
0
sage: L.duality_pairing_by_coercion(L[1,1,1], F[1,2])
1
sage: F.duality_pairing_by_coercion(F[1,2], L[1,1,1])
1
```

TESTS:

The result has the right parent even if the sum is empty:

```
sage: x = F.duality_pairing_by_coercion(F.zero(), L.zero()); x
0
sage: parent(x)
Rational Field
```

duality_pairing_matrix(*basis*, *degree*)

The matrix of scalar products between elements of NSym and elements of QSym.

INPUT:

- `basis` – A basis of the dual Hopf algebra
- `degree` – a non-negative integer

OUTPUT:

- The matrix of scalar products between the basis `self` and the basis `basis` in the dual Hopf algebra in degree `degree`.

EXAMPLES:

The ribbon basis of NCSF is dual to the fundamental basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing_matrix(F, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: F.duality_pairing_matrix(R, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The complete basis of NCSF is dual to the monomial basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing_matrix(M, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: M.duality_pairing_matrix(S, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The matrix between the ribbon basis of NCSF and the monomial basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: R.duality_pairing_matrix(M, 3)
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
sage: M.duality_pairing_matrix(R, 3)
[ 1  0  0  0]
[-1  1  0  0]
[-1  0  1  0]
[ 1 -1 -1  1]
```

The matrix between the complete basis of NCSF and the fundamental basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing_matrix(F, 3)
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

A base case test:

```
sage: R.duality_pairing_matrix(M,0)
[1]
```

one_basis()

Return the empty composition.

OUTPUT

•The empty composition.

EXAMPLES:

```
sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.Elementary_with_ca
sage: parent(L).one_basis()
[]
```

skew(*x*, *y*, *side='left'*)

Return a function `x` in `self` skewed by a function `y` in the Hopf dual of `self`.

INPUT:

- `x` – a non-commutative or quasi-symmetric function; it is an element of `self`
- `y` – a quasi-symmetric or non-commutative symmetric function; it is an element of the dual algebra of `self`
- `side` – (default: `'left'`) either `'left'` or `'right'`

OUTPUT:

- The result of skewing the element `x` by the Hopf algebra element `y` (either from the left or from the right, as determined by `side`), written in the basis `self`.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.skew(S[2,2,2], F[1,1])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1]
sage: S.skew(S[2,2,2], F[2])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1] + 3*S[2, 2]

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.skew(R[2,2,2], F[1,1])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 2*R[2, 2] + R[3, 1] + R[4]
sage: R.skew(R[2,2,2], F[2])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 3*R[2, 2] + R[3, 1] + R[4]

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.skew(M[3,2], S[2])
0
sage: M.skew(M[3,2], S[2], side='right')
M[3]
sage: M.skew(M[3,2], S[3])
M[2]
sage: M.skew(M[3,2], S[3], side='right')
0
```

TESTS:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.skew([2,1], [1])
Traceback (most recent call last):
...
AssertionError: x must be an element of Non-Commutative Symmetric Functions over the Rat
sage: R([2,1]).skew_by([1])
Traceback (most recent call last):
...
AssertionError: y must be an element of Quasisymmetric functions over the Rational Field
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F([2,1]).skew_by([1])
Traceback (most recent call last):
```

```
...
AssertionError: y must be an element of Non-Commutative Symmetric Functions over the Rat
```

sum_of_fatter_compositions(*composition*)

Return the sum of all fatter compositions.

INPUT:

- composition – a composition

OUTPUT:

- the sum of all basis elements which are indexed by compositions fatter (coarser?) than composition.

EXAMPLES:

```
sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_fatter_compositions(Composition([2,1]))
L[2, 1] + L[3]
sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_fatter_compositions(Composition([1,3]))
R[1, 3] + R[4]
```

sum_of_finer_compositions(*composition*)

Return the sum of all finer compositions.

INPUT:

- composition – a composition

OUTPUT:

- The sum of all basis self elements which are indexed by compositions finer than composition.

EXAMPLES:

```
sage: L=NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_finer_compositions(Composition([2,1]))
L[1, 1, 1] + L[2, 1]
sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_finer_compositions(Composition([1,3]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

sum_of_partition_rearrangements(*par*)

Return the sum of all basis elements indexed by compositions which can be sorted to obtain a given partition.

INPUT:

- par – a partition

OUTPUT:

- The sum of all self basis elements indexed by compositions which are permutations of par (without multiplicity).

EXAMPLES:

```
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.sum_of_partition_rearrangements(Partition([2,2,1]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([3,2,1]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

BasesOfQSymOrNCSF.**super_categories**()

TESTS:

```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import BasesOfQSymOrNCSF
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: BasesOfQSymOrNCSF(QSym).super_categories()
[Category of realizations of Quasisymmetric functions over the Rational Field,
 Category of graded hopf algebras with basis over Rational Field,
 Join of Category of realizations of hopf algebras over Rational Field and
 Category of graded algebras over Rational Field]
```

class sage.combinat.ncsf_qsym.generic_basis_code.**GradedModulesWithInternalProduct**(*base*, *name=None*)

Bases: sage.categories.category_types.Category_over_base_ring

Constructs the class of modules with internal product. This is used to give an internal product structure to the non-commutative symmetric functions.

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import GradedModulesWithInternalProduct
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R in GradedModulesWithInternalProduct(QQ)
True
```

class ElementMethods

internal_product(*other*)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions f and g and any quasi-symmetric function h satisfy

$$\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle ,$$

where we write $\Delta^{\times}(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f * g$ denotes the internal product of the non-commutative symmetric functions f and g.

If f and g are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f * g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If I and J are two compositions of lengths p and q, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions S^I and S^J have internal product

$$S^I * S^J = \sum S^{\operatorname{comp} M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbf{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is I (that is, the sum of the entries of the r-th row is the r-th part of I for all r) and whose column sum vector is J (that is, the sum of all entries of the s-th row is the s-th part of J for all s). Here, for any $M \in \mathbf{N}^{p \times q}$, we denote by $\operatorname{comp} M$ the composition obtained by reading the entries of the matrix M in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let I and J be two compositions of lengths p and q, respectively, having the same size $|I| = |J|$. We denote by Ψ^K the element of the Psi basis corresponding to any composition K.

- If $p > q$, then $\Psi^I * \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\widetilde{\delta}_{I,J}$ denote the integer 1 if the compositions I and J are permutations of each other, and the integer 0 otherwise. For every positive integer i, let m_i denote the number of parts of I equal to i. Then, $\Psi^I * \Psi^J$ equals $\widetilde{\delta}_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I$.
- Now assume that $p < q$. Write the composition I as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by Γ_K the non-commutative symmetric function $k_1[\ldots[[\Psi_{k_1}, \Psi_{k_2}], \Psi_{k_3}], \ldots \Psi_{k_s}]$. For any subset A of $\{1, 2, \ldots, q\}$, let J_A be the composition obtained from J by removing the r-th parts for all $r \notin A$ (while keeping the r-th parts for all $r \in A$ in order). Then, $\Psi^I * \Psi^J$ equals the sum of $\Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into p parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See `OrderedSetPartition()` for the meaning of "ordered set partition".)

Aliases for `internal_product()` are `itensor()` and `kronecker_product()`.

INPUT:

- `other` – another non-commutative symmetric function

OUTPUT:

- The result of taking the internal product of `self` with `other`.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \left< g, h'
....:     result = h.base_ring().zero()
....:     h_parent = h.parent()
....:     for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().it
....:         result += coeff * f.duality_pairing(h_parent[partition_pair[0]]) * g.duali
....:     return result
sage: def testall(n):
....:     return all( all( all( tensor_incopr(S[u], S[v], M[w]) == (S[u].itensor(S[v])).
....:                           for w in Compositions(n) )
....:                     for v in Compositions(n) )
....:                 for u in Compositions(n) )
sage: testall(2)
True
sage: testall(3)  # long time
True
sage: testall(4)  # long time
True
```

The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
```

```
....:           == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_funct
....:           for I in Compositions(3) )
....:      for J in Compositions(3) )
True
```

itensor(*other*)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions f and g and any quasi-symmetric function h satisfy

$$\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle ,$$

where we write $\Delta^{\times}(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f*g$ denotes the internal product of the non-commutative symmetric functions f and g.

If f and g are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f * g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If I and J are two compositions of lengths p and q, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions S^I and S^J have internal product

$$S^I * S^J = \sum S^{\operatorname{comp} M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbf{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is I (that is, the sum of the entries of the r-th row is the r-th part of I for all r) and whose column sum vector is J (that is, the sum of all entries of the s-th row is the s-th part of J for all s). Here, for any $M \in \mathbf{N}^{p \times q}$, we denote by $\operatorname{comp} M$ the composition obtained by reading the entries of the matrix M in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let I and J be two compositions of lengths p and q, respectively, having the same size $|I| = |J|$. We denote by Ψ^K the element of the Psi basis corresponding to any composition K.

- If $p > q$, then $\Psi^I * \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\widetilde{\delta}_{I,J}$ denote the integer 1 if the compositions I and J are permutations of each other, and the integer 0 otherwise. For every positive integer i, let m_i denote the number of parts of I equal to i. Then, $\Psi^I * \Psi^J$ equals $\widetilde{\delta}_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I$.
- Now assume that $p < q$. Write the composition I as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by Γ_K the non-commutative symmetric function $k_1[\ldots[[\Psi_{k_1}, \Psi_{k_2}], \Psi_{k_3}], \ldots \Psi_{k_s}]$. For any subset A of $\{1, 2, \ldots, q\}$, let J_A be the composition obtained from J by removing the r-th parts for all $r \notin A$ (while keeping the r-th parts for all $r \in A$ in order). Then, $\Psi^I * \Psi^J$ equals the sum of $\Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into p parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See `OrderedSetPartition()` for the meaning of "ordered set partition".)

Aliases for `internal_product()` are `itensor()` and `kronecker_product()`.

INPUT:

- `other` – another non-commutative symmetric function

OUTPUT:

- The result of taking the internal product of `self` with `other`.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \left< g, h'
....:     result = h.base_ring().zero()
....:     h_parent = h.parent()
....:     for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().it
....:         result += coeff * f.duality_pairing(h_parent[partition_pair[0]]) * g.duali
....:     return result
sage: def testall(n):
....:     return all( all( all( tensor_incopr(S[u], S[v], M[w]) == (S[u].itensor(S[v])).
....:                           for w in Compositions(n) )
....:                       for v in Compositions(n) )
....:                   for u in Compositions(n) )
sage: testall(2)
True
sage: testall(3)  # long time
True
sage: testall(4)  # long time
True
```

The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
....:           == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_funct
....:           for I in Compositions(3) )
....:      for J in Compositions(3) )
True
```

kronecker_product (*other*)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions f and g and any quasi-symmetric function h satisfy

$$\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle ,$$

where we write $\Delta^{\times}(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f * g$ denotes the internal product of the non-commutative symmetric functions f and g.

If f and g are two homogeneous elements of $NSym$ having distinct degrees, then the internal product

$f * g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If I and J are two compositions of lengths p and q, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions S^I and S^J have internal product

$$S^I * S^J = \sum S^{\operatorname{comp} M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbf{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is I (that is, the sum of the entries of the r-th row is the r-th part of I for all r) and whose column sum vector is J (that is, the sum of all entries of the s-th row is the s-th part of J for all s). Here, for any $M \in \mathbf{N}^{p \times q}$, we denote by $\operatorname{comp} M$ the composition obtained by reading the entries of the matrix M in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let I and J be two compositions of lengths p and q, respectively, having the same size $|I| = |J|$. We denote by Ψ^K the element of the Psi basis corresponding to any composition K.

- If $p > q$, then $\Psi^I * \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\widetilde{\delta}_{I,J}$ denote the integer 1 if the compositions I and J are permutations of each other, and the integer 0 otherwise. For every positive integer i, let m_i denote the number of parts of I equal to i. Then, $\Psi^I * \Psi^J$ equals $\widetilde{\delta}_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I$.
- Now assume that $p < q$. Write the composition I as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by Γ_K the non-commutative symmetric function $k_1[\ldots[[\Psi_{k_1}, \Psi_{k_2}], \Psi_{k_3}], \ldots \Psi_{k_s}]$. For any subset A of $\{1, 2, \ldots, q\}$, let J_A be the composition obtained from J by removing the r-th parts for all $r \notin A$ (while keeping the r-th parts for all $r \in A$ in order). Then, $\Psi^I * \Psi^J$ equals the sum of $\Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into p parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See `OrderedSetPartition()` for the meaning of "ordered set partition".)

Aliases for `internal_product()` are `itensor()` and `kronecker_product()`.

INPUT:

- `other` – another non-commutative symmetric function

OUTPUT:

- The result of taking the internal product of `self` with `other`.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \left< g, h'
....:     result = h.base_ring().zero()
....:     h_parent = h.parent()
....:     for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().it
....:         result += coeff * f.duality_pairing(h_parent[partition_pair[0]]) * g.duali
....:     return result
```

```
sage: def testall(n):
....:     return all( all( all( tensor_incopr(S[u], S[v], M[w]) == (S[u].itensor(S[v])).
....:                           for w in Compositions(n) )
....:                       for v in Compositions(n) )
....:                   for u in Compositions(n) )
sage: testall(2)
True
sage: testall(3)  # long time
True
sage: testall(4)  # long time
True
```

The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
....:           == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_funct
....:           for I in Compositions(3) )
....:       for J in Compositions(3) )
True
```

class GradedModulesWithInternalProduct.**ParentMethods**

internal_product()

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method internal_product_on_basis() bilinearly, if available, or using the method internal_product_by_coercion().

OUTPUT:

•The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in t
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R.internal_product
<bound method ....internal_product_by_coercion ...>
sage: R.internal_product_by_coercion(R[1, 1], R[1,1])
R[2]
sage: R.internal_product(R[2,2], R[1,2])
0
```

internal_product_on_basis(*I*, *J*)

The internal product of the two basis elements indexed by I and J (optional)

INPUT:

•I, J – compositions indexing two elements of the basis of self

Returns the internal product of the corresponding basis elements. If this method is implemented, the internal product is defined from it by linearity.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2], [1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2], [2,1])
0
```

itensor()

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method internal_product_on_basis() bilinearly, if available, or using the method internal_product_by_coercion().

OUTPUT:

•The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in t
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R.internal_product
<bound method ....internal_product_by_coercion ...>
sage: R.internal_product_by_coercion(R[1, 1], R[1,1])
R[2]
sage: R.internal_product(R[2,2], R[1,2])
0
```

kronecker_product()

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method internal_product_on_basis() bilinearly, if available, or using the method internal_product_by_coercion().

OUTPUT:

•The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in t
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R.internal_product
<bound method ....internal_product_by_coercion ...>
sage: R.internal_product_by_coercion(R[1, 1], R[1,1])
```

```
R[2]
sage: R.internal_product(R[2,2], R[1,2])
0
```

class GradedModulesWithInternalProduct.**Realizations**(*category*, **args*)

Bases: sage.categories.realizations.RealizationsCategory

TESTS:

```
sage: from sage.categories.covariant_functorial_construction import CovariantConstructionCat
sage: class FooBars(CovariantConstructionCategory):
....:     _functor_category = "FooBars"
....:     _base_category_class = (Category,)
sage: Category.FooBars = lambda self: FooBars.category_of(self)
sage: C = FooBars(ModulesWithBasis(ZZ))
sage: C
Category of foo bars of modules with basis over Integer Ring
sage: C.base_category()
Category of modules with basis over Integer Ring
sage: latex(C)
\mathbf{FooBars}(\mathbf{ModulesWithBasis}_{\Bold{Z}})
sage: import __main__; __main__.FooBars = FooBars # Fake FooBars being defined in a python m
sage: TestSuite(C).run()
```

class ParentMethods

internal_product_by_coercion(*left*, *right*)

Internal product of `left` and `right`.

This is a default implementation that computes the internal product in the realization specified by `self.realization_of().a_realization()`.

INPUT:

- `left` – an element of the non-commutative symmetric functions
- `right` – an element of the non-commutative symmetric functions

OUTPUT:

- The internal product of `left` and `right`.

EXAMPLES:

```
sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.internal_product_by_coercion(S[2,1], S[3])
S[2, 1]
sage: S.internal_product_by_coercion(S[2,1], S[4])
0
```

GradedModulesWithInternalProduct.**super_categories**()

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import GradedModulesWithInternalProduc
sage: GradedModulesWithInternalProduct(ZZ).super_categories()
[Category of graded modules over Integer Ring]
```

5.1.129 Non-Commutative Symmetric Functions

class sage.combinat.ncsf_qsym.ncsf.**NonCommutativeSymmetricFunctions**(*R*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The abstract algebra of non-commutative symmetric functions.

We construct the abstract algebra of non-commutative symmetric functions over the rational numbers:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
sage: S = NCSF.complete()
sage: R = NCSF.ribbon()
sage: S[2,1]*R[1,2]
S[2, 1, 1, 2] - S[2, 1, 3]
```

NCSF is the unique free (non-commutative!) graded connected algebra with one generator in each degree:

```
sage: NCSF.category()
Join of Category of hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
    and Category of coalgebras over Rational Field with realizations

sage: [S[i].degree() for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We use the Sage standard renaming idiom to get shorter outputs:

```
sage: NCSF.rename("NCSF")
sage: NCSF
NCSF
```

NCSF has many representations as a concrete algebra. Each of them has a distinguished basis, and its elements are expanded in this basis. Here is the Ψ (`Psi`) representation:

```
sage: Psi = NCSF.Psi()
sage: Psi
NCSF in the Psi basis
```

Elements of `Psi` are linear combinations of basis elements indexed by compositions:

```
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

The basis itself is accessible through:

```
sage: Psi.basis()
Lazy family (Term map from Compositions of non-negative integers...
sage: Psi.basis().keys()
Compositions of non-negative integers
```

To construct an element one can therefore do:

```
sage: Psi.basis()[Composition([2,1,3])]
Psi[2, 1, 3]
```

As this is rather cumbersome, the following abuses of notation are allowed:

```
sage: Psi[Composition([2, 1, 3])]
Psi[2, 1, 3]
sage: Psi[[2, 1, 3]]
Psi[2, 1, 3]
sage: Psi[2, 1, 3]
Psi[2, 1, 3]
```

or even:

```
sage: Psi[(i for i in [2, 1, 3])]
Psi[2, 1, 3]
```

Unfortunately, due to a limitation in Python syntax, one cannot use:

```
sage: Psi[]       # not implemented
```

Instead, you can use:

```
sage: Psi[[]]
Psi[]
```

Now, we can construct linear combinations of basis elements:

```
sage: Psi[2,1,3] + 2 * (Psi[4] + Psi[2,1])
2*Psi[2, 1] + Psi[2, 1, 3] + 2*Psi[4]
```

Algebra structure

To start with, `Psi` is a graded algebra, the grading being induced by the size of compositions. The one is the basis element indexed by the empty composition:

```
sage: Psi.one()
Psi[]
sage: S.one()
S[]
sage: R.one()
R[]
```

As we have seen above, the `Psi` basis is multiplicative; that is multiplication is induced by linearity from the concatenation of compositions:

```
sage: Psi[1,3] * Psi[2,1]
Psi[1, 3, 2, 1]
sage: (Psi.one() + 2 * Psi[1,3]) * Psi[2, 4]
2*Psi[1, 3, 2, 4] + Psi[2, 4]
```

Hopf algebra structure

`Psi` is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; those are primitive:

```
sage: Psi[1].coproduct()
Psi[] # Psi[1] + Psi[1] # Psi[]
sage: Psi[2].coproduct()
Psi[] # Psi[2] + Psi[2] # Psi[]
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: Psi[1,2].coproduct()
Psi[] # Psi[1, 2] + Psi[1] # Psi[2] + Psi[1, 2] # Psi[] + Psi[2] # Psi[1]
```

The algebra and coalgebra structures on `Psi` combine to form a bialgebra structure, which cooperates with the grading to form a connected graded bialgebra. Thus, as any connected graded bialgebra, `Psi` is a Hopf algebra. Over `QQ` (or any other $\mathbf{Q}$-algebra), this Hopf algebra `Psi` is isomorphic to the tensor algebra of its space of primitive elements.

The antipode is an anti-algebra morphism; in the `Psi` basis, it sends the generators to their opposites and changes their sign if they are of odd degree:

```
sage: Psi[3].antipode()
-Psi[3]
sage: Psi[1,3,2].antipode()
-Psi[2, 3, 1]
sage: Psi[1,3,2].coproduct().apply_multilinear_morphism(lambda be,ga: Psi(be)*Psi(ga).antipode()
0
```

The counit is defined by sending all elements of positive degree to zero:

```
sage: S[3].degree(), S[3,1,2].degree(), S.one().degree()
(3, 6, 0)
sage: S[3].counit()
0
sage: S[3,1,2].counit()
0
sage: S.one().counit()
1
sage: (S[3] - 2*S[3,1,2] + 7).counit()
7
sage: (R[3] - 2*R[3,1,2] + 7).counit()
7
```

It is possible to change the prefix used to display the basis elements using the method `print_options()`. Say that for instance one wanted to display the `Complete` basis as having a prefix `H` instead of the default `S`:

```
sage: H = NCSF.complete()
sage: H.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
sage: H.print_options(prefix='H')
sage: H.an_element()
2*H[] + 2*H[1] + 3*H[1, 1]
sage: H.print_options(prefix='S') #restore to 'S'
```

Concrete representations

NCSF admits the concrete realizations defined in [NCSF1]:

```
sage: Phi        = NCSF.Phi()
sage: Psi        = NCSF.Psi()
sage: ribbon     = NCSF.ribbon()
sage: complete   = NCSF.complete()
sage: elementary = NCSF.elementary()
```

To change from one basis to another, one simply does:

```
sage: Phi(Psi[1])
Phi[1]
sage: Phi(Psi[3])
-1/4*Phi[1, 2] + 1/4*Phi[2, 1] + Phi[3]
```

In general, one can mix up different bases in computations:

```
sage: Phi[1] * Psi[1]
Phi[1, 1]
```

Some of the changes of basis are easy to guess:

```
sage: ribbon(complete[1,3,2])
R[1, 3, 2] + R[1, 5] + R[4, 2] + R[6]
```

This is the sum of all fatter compositions. Using the usual Möbius function for the boolean lattice, the inverse change of basis is given by the alternating sum of all fatter compositions:

```
sage: complete(ribbon[1,3,2])
S[1, 3, 2] - S[1, 5] - S[4, 2] + S[6]
```

The analogue of the elementary basis is the sum over all finer compositions than the 'complement' of the composition in the ribbon basis:

```
sage: Composition([1,3,2]).complement()
[2, 1, 2, 1]
sage: ribbon(elementary([1,3,2]))
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1] + R[2, 1, 2, 1]
```

By Möbius inversion on the composition poset, the ribbon basis element corresponding to a composition I is then the alternating sum over all compositions fatter than the complement composition of I in the elementary basis:

```
sage: elementary(ribbon[2,1,2,1])
L[1, 3, 2] - L[1, 5] - L[4, 2] + L[6]
```

The Φ (`Phi`) and Ψ bases are computed by changing to and from the `Complete` basis. The expansion of Ψ basis is given in Proposition 4.5 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{\pi_u(J, I)} \Psi^J$$

and

$$\Psi^I = \sum_{J \geq I} (-1)^{\ell(J)-\ell(I)} lp(J, I) S^J$$

where the coefficients $\pi_u(J, I)$ and $lp(J, I)$ are coefficients in the methods `coeff_pi()` and `coeff_lp()` respectively. For example:

```
sage: Psi(complete[3])
1/6*Psi[1, 1, 1] + 1/3*Psi[1, 2] + 1/6*Psi[2, 1] + 1/3*Psi[3]
sage: complete(Psi[3])
S[1, 1, 1] - 2*S[1, 2] - S[2, 1] + 3*S[3]
```

The `Phi` basis is another analogue of the power sum basis from the algebra of symmetric functions and the expansion in the Complete basis is given in Proposition 4.9 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{sp(J, I)} \Phi^J$$

and

$$\Phi^I = \sum_{J \geq I} (-1)^{\ell(J)-\ell(I)} \frac{\prod_i I_i}{\ell(J, I)} S^J$$

where the coefficients $sp(J, I)$ and $\ell(J, I)$ are coefficients in the methods `coeff_sp()` and `coeff_ell()` respectively. For example:

```
sage: Phi(complete[3])
1/6*Phi[1, 1, 1] + 1/4*Phi[1, 2] + 1/4*Phi[2, 1] + 1/3*Phi[3]
sage: complete(Phi[3])
S[1, 1, 1] - 3/2*S[1, 2] - 3/2*S[2, 1] + 3*S[3]
```

Here is how to fetch the conversion morphisms:

```
sage: f = complete.coerce_map_from(elementary); f
Generic morphism:
  From: NCSF in the Elementary basis
  To:   NCSF in the Complete basis
sage: g = elementary.coerce_map_from(complete); g
Generic morphism:
  From: NCSF in the Complete basis
  To:   NCSF in the Elementary basis
sage: f.category()
Category of homsets of unital magmas and right modules over Rational Field and
  left modules over Rational Field
sage: f(elementary[1,2,2])
S[1, 1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
sage: g(complete[1,2,2])
L[1, 1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
sage: h = f*g; h
Composite map:
  From: NCSF in the Complete basis
  To:   NCSF in the Complete basis
  Defn:   Generic morphism:
          From: NCSF in the Complete basis
          To:   NCSF in the Elementary basis
        then
          Generic morphism:
          From: NCSF in the Elementary basis
          To:   NCSF in the Complete basis
sage: h(complete[1,3,2])
S[1, 3, 2]
```

Additional concrete representations

NCSF has some additional bases which appear in the literature:

```
sage: Monomial                 = NCSF.Monomial()
sage: Immaculate               = NCSF.Immaculate()
sage: dualQuasisymmetric_Schur = NCSF.dualQuasisymmetric_Schur()
```

The `Monomial` basis was introduced in [Tev2007] and the `Immaculate` basis was introduced in [BBSSZ2012]. The `Quasisymmetric_Schur` were defined in [QSCHUR] and the dual basis is implemented here as `dualQuasisymmetric_Schur`. Refer to the documentation for the use and definition of these bases.

Todo

•implement fundamental, forgotten, and simple (coming from the simple modules of HS_n) bases.

We revert back to the original name from our custom short name NCSF:

```
sage: NCSF
NCSF
```

```
sage: NCSF.rename()
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
```

TESTS:

```
sage: TestSuite(Phi).run()
sage: TestSuite(Psi).run()
sage: TestSuite(complete).run()
```

class Bases (*parent_with_realization*)

Bases: `sage.categories.realizations.Category_realization_of_parent`

Category of bases of non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.Bases()
Category of bases of Non-Commutative Symmetric Functions over the Rational Field
sage: R = N.Ribbon()
sage: R in N.Bases()
True
```

class ElementMethods

bernstein_creation_operator(*n*)

Return the image of `self` under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator $\mathbb{B}_n$ is defined as the endomorphism of the space $NSym$ of noncommutative symmetric functions which sends every f to

$$\sum_{i \geq 0} (-1)^i H_{n+i} F_{1^i}^{\perp},$$

where usual notations are in place (the letter H stands for the complete basis of $NSym$, the letter F stands for the fundamental basis of the algebra $QSym$ of quasisymmetric functions, and $F_{1^i}^{\perp}$ means skewing (`skew_by()`) by F_{1^i}). Notice that F_{1^i} is nothing other than the elementary symmetric function e_i.

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions (`bernstein_creation_operator()`), and studied further in [BBSSZ2012], mainly in the context of immaculate functions (`Immaculate`). In fact, if $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ is an m-tuple of integers, then

$$\mathbb{B}_n I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} = I_{(n, \alpha_1, \alpha_2, \ldots, \alpha_m)},$$

where $I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)}$ is the immaculate function associated to the m-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ (see `immaculate_function()`).

EXAMPLES:

We get the immaculate functions by repeated application of Bernstein creation operators:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: I = NSym.I()
sage: S = NSym.S()
sage: def immaculate_by_bernstein(xs):
....:     # immaculate function corresponding to integer
....:     # tuple ``xs``, computed by iterated application
```

```
....:     # of Bernstein creation operators.
....:     res = S.one()
....:     for i in reversed(xs):
....:         res = res.bernstein_creation_operator(i)
....:     return res
sage: import itertools
sage: all( immaculate_by_bernstein(p) == I.immaculate_function(p)
....:      for p in itertools.product(range(-1, 3), repeat=3))
True
```

Some examples:

```
sage: S[3,2].bernstein_creation_operator(-2)
S[2, 1]
sage: S[3,2].bernstein_creation_operator(-1)
S[1, 2, 1] - S[2, 2] - S[3, 1]
sage: S[3,2].bernstein_creation_operator(0)
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
sage: S[3,2].bernstein_creation_operator(1)
S[1, 3, 2] - S[2, 2, 2] - S[2, 3, 1] + S[3, 2, 1]
sage: S[3,2].bernstein_creation_operator(2)
S[2, 3, 2] - S[3, 2, 2] - S[3, 3, 1] + S[4, 2, 1]
```

chi()

Return the commutative image of a non-commutative symmetric function.

OUTPUT:

•The commutative image of `self`. This will be a symmetric function.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

expand(*n*, *alphabet='x'*)

Expand the noncommutative symmetric function into an element of a free algebra in `n` indeterminates of an alphabet, which by default is `'x'`.

INPUT:

•`n` – a nonnegative integer; the number of variables in the expansion

•`alphabet` – (default: `'x'`); the alphabet in which `self` is to be expanded

OUTPUT:

•An expansion of `self` into the `n` variables specified by `alphabet`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[3].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2
 + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3
sage: L = NSym.L()
sage: L[3].expand(3)
x2*x1*x0
sage: L[2].expand(3)
x1*x0 + x2*x0 + x2*x1
```

```
sage: L[3].expand(4)
x2*x1*x0 + x3*x1*x0 + x3*x2*x0 + x3*x2*x1
sage: Psi = NSym.Psi()
sage: Psi[2, 1].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1*x0 + x0*x1^2 + x0*x1*x2
 + x0*x2*x0 + x0*x2*x1 + x0*x2^2 - x1*x0^2 - x1*x0*x1
 - x1*x0*x2 + x1^2*x0 + x1^3 + x1^2*x2 + x1*x2*x0
 + x1*x2*x1 + x1*x2^2 - x2*x0^2 - x2*x0*x1 - x2*x0*x2
 - x2*x1*x0 - x2*x1^2 - x2*x1*x2 + x2^2*x0 + x2^2*x1 + x2^3
```

One can use a different set of variables by adding an optional argument `alphabet=...`:

```
sage: L[3].expand(4, alphabet="y")
y2*y1*y0 + y3*y1*y0 + y3*y2*y0 + y3*y2*y1
```

TESTS:

```
sage: (3*S([])).expand(2)
3
sage: L[4,2].expand(0)
0
sage: S([]).expand(0)
1
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2
 + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3
```

Todo

So far this is only implemented on the elementary basis, and everything else goes through coercion. Maybe it is worth shortcutting some of the other bases?

---

left_padded_kronecker_product(*x*)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two non-commutative symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the internal product (`internal_product()`) on the space of non-commutative symmetric functions. For any composition I, let S^I denote the complete homogeneous symmetric function indexed by I. For any compositions α, β, γ, let $g^{\gamma}_{\alpha,\beta}$ denote the coefficient of S^γ in the internal product $S^\alpha * S^\beta$. For every composition $I = (i_1, i_2, \ldots, i_k)$ and every integer $n > |I|$, define the *'n'-completion of 'I'* to be the composition $(n - |I|, i_1, i_2, \ldots, i_k)$; this n-completion is denoted by $I[n]$. Then, for any compositions α and β and every integer $n > |\alpha| + |\beta|$, we can write the internal product $S^{\alpha[n]} * S^{\beta[n]}$ in the form

$$S^{\alpha[n]} * S^{\beta[n]} = \sum_\gamma g^{\gamma[n]}_{\alpha[n],\beta[n]} S^{\gamma[n]}$$

with γ ranging over all compositions. The coefficients $g^{\gamma[n]}_{\alpha[n],\beta[n]}$ are independent on n. These coefficients $g^{\gamma[n]}_{\alpha[n],\beta[n]}$ are denoted by $\widetilde{g}^{\gamma}_{\alpha,\beta}$, and the non-commutative symmetric function

$$\sum_\gamma \widetilde{g}^{\gamma}_{\alpha,\beta} S^\gamma$$

is said to be the *left-padded Kronecker product* of S^α and S^β. By bilinearity, this extends to a definition of a left-padded Kronecker product of any two non-commutative symmetric functions.

The left-padded Kronecker product on the non-commutative symmetric functions lifts the left-padded Kronecker product on the symmetric functions. More precisely: Let π denote the canonical projection (`to_symmetric_function()`) from the non-commutative symmetric functions to the symmetric functions. Then, any two non-commutative symmetric functions f and g satisfy

$$\pi(f \overline{*} g) = \pi(f) \overline{*} \pi(g),$$

where the $\overline{*}$ on the left-hand side denotes the left-padded Kronecker product on the non-commutative symmetric functions, and the $\overline{*}$ on the right-hand side denotes the left-padded Kronecker product on the symmetric functions.

INPUT:

- `x` – element of the ring of non-commutative symmetric functions over the same base ring as `self`

OUTPUT:

- the left-padded Kronecker product of `self` with `x` (an element of the ring of non-commutative symmetric functions in the same basis as `self`)

AUTHORS:

- Darij Grinberg (15 Mar 2014)

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[2,1].left_padded_kronecker_product(S[3])
S[1, 1, 1, 1] + S[1, 2, 1] + S[2, 1] + S[2, 1, 1, 1] + S[2, 2, 1] + S[3, 2, 1]
sage: S[2,1].left_padded_kronecker_product(S[1])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1]
sage: S[1].left_padded_kronecker_product(S[2,1])
S[1, 1, 1] + S[2, 1] + S[2, 1, 1]
sage: S[1,1].left_padded_kronecker_product(S[2])
S[1, 1] + 2*S[1, 1, 1] + S[2, 1, 1]
sage: S[1].left_padded_kronecker_product(S[1,2,1])
S[1, 1, 1, 1] + S[1, 2, 1] + S[1, 2, 1, 1] + S[2, 1, 1]
sage: S[2].left_padded_kronecker_product(S[3])
S[1, 2] + S[2, 1, 1] + S[3, 2]
```

Taking the left-padded Kronecker product with $1 = S$ is the identity map on the ring of non-commutative symmetric functions:

```
sage: all( S[Composition([])].left_padded_kronecker_product(S[lam])
....:      == S[lam].left_padded_kronecker_product(S[Composition([])])
....:      == S[lam] for i in range(4)
....:      for lam in Compositions(i) )
True
```

Here is a rule for the left-padded Kronecker product of S_1 (this is the same as $S^{(1)}$) with any complete homogeneous function: Let I be a composition. Then, the left-padded Kronecker product of S_1 and S^I is $\sum_K a_K S^K$, where the sum runs over all compositions K, and the coefficient a_K is defined as the number of ways to obtain K from I by one of the following two operations:

- Insert a 1 at the end of I.
- Subtract 1 from one of the entries of I (and remove the entry if it thus becomes 0), and insert a 1 at the end of I.

We check this for compositions of size ≤ 4:

```
sage: def mults1(I):
....:     # Left left-padded Kronecker multiplication by S[1].
....:     res = S[I[:] + [1]]
....:     for k in range(len(I)):
....:         I2 = I[:]
```

```
....:             if I2[k] == 1:
....:                 I2 = I2[:k] + I2[k+1:]
....:             else:
....:                 I2[k] -= 1
....:             res += S[I2 + [1]]
....:         return res
sage: all( mults1(I) == S[1].left_padded_kronecker_product(S[I])
....:       for i in range(5) for I in Compositions(i) )
True
```

A similar rule can be made for the left-padded Kronecker product of any complete homogeneous function with S_1: Let I be a composition. Then, the left-padded Kronecker product of S^I and S_1 is $\sum_K b_K S^K$, where the sum runs over all compositions K, and the coefficient b_K is defined as the number of ways to obtain K from I by one of the following two operations:

- Insert a 1 at the front of I.
- Subtract 1 from one of the entries of I (and remove the entry if it thus becomes 0), and insert a 1 right after this entry.

We check this for compositions of size ≤ 4:

```
sage: def mults2(I):
....:     # Left left-padded Kronecker multiplication by S[1].
....:     res = S[[1] + I[:]]
....:     for k in range(len(I)):
....:         I2 = I[:]
....:         i2k = I2[k]
....:         if i2k != 1:
....:             I2 = I2[:k] + [i2k-1, 1] + I2[k+1:]
....:         res += S[I2]
....:     return res
sage: all( mults2(I) == S[I].left_padded_kronecker_product(S[1])
....:       for i in range(5) for I in Compositions(i) )
True
```

Checking the $\pi(f \overline{*} g) = \pi(f) \overline{*} \pi(g)$ equality:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: def testpi(n):
....:     for I in Compositions(n):
....:         for J in Compositions(n):
....:             a = R[I].to_symmetric_function()
....:             b = R[J].to_symmetric_function()
....:             x = a.left_padded_kronecker_product(b)
....:             y = R[I].left_padded_kronecker_product(R[J])
....:             y = y.to_symmetric_function()
....:             if x != y:
....:                 return False
....:     return True
sage: testpi(3)
True
```

TESTS:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: (2*S([])).left_padded_kronecker_product(3*S([]))
6*S[]
```

Different bases and base rings:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
```

```
sage: L = NSym.L()
sage: L(S[2].left_padded_kronecker_product(L[2]))
L[1, 1, 1] + L[2] + L[2, 1, 1] - L[2, 2]
sage: S(L[2].left_padded_kronecker_product(S[1,1]))
S[1, 1] + 2*S[1, 1, 1] + S[1, 1, 1, 1] - S[1, 1, 2]

sage: NSym = NonCommutativeSymmetricFunctions(CyclotomicField(12))
sage: S = NSym.S()
sage: L = NSym.L()
sage: v = L[2].left_padded_kronecker_product(L[2]); v
L[1, 1] + L[1, 1, 1] + (-1)*L[2] + L[2, 2]
sage: parent(v)
Non-Commutative Symmetric Functions over the Cyclotomic Field of order 12 and degree

sage: NSym = NonCommutativeSymmetricFunctions(Zmod(14))
sage: S = NSym.S()
sage: L = NSym.L()
sage: v = L[2].left_padded_kronecker_product(L[2]); v
L[1, 1] + L[1, 1, 1] + 13*L[2] + L[2, 2]
sage: parent(v)
Non-Commutative Symmetric Functions over the Ring of integers modulo 14 in the Elemen

sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: v = R[1].left_padded_kronecker_product(R[1]); parent(v)
Non-Commutative Symmetric Functions over the Integer Ring in the Ribbon basis
```

omega_involution()

Return the image of the noncommutative symmetric function `self` under the omega involution.

The omega involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to the n-th elementary non-commutative symmetric function Λ_n. This omega involution is denoted by ω. It can be shown that every composition I satisfies

$$\omega(S^I) = \Lambda^{I^r}, \quad \omega(\Lambda^I) = S^{I^r}, \quad \omega(R_I) = R_{I^t}, \quad \omega(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^{I^r}, \omega(\Psi^I) = (-1)^{|I|-\ell(I)}\Psi^{I^r},$$

where I^r denotes the reversed composition of I, and I^t denotes the conjugate composition of I, and $\ell(I)$ denotes the length of the composition I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, Φ for that of the power-sums of the second kind, and Ψ for that of the power-sums of the first kind). More generally, if f is a homogeneous element of $NCSF$ of degree n, then

$$\omega(f) = (-1)^n S(f),$$

where S denotes the antipode of $NCSF$.

The omega involution ω is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(\omega(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The omega involution on $NCSF$ is adjoint to the omega involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The omega involution has been denoted by ω in [LMvW13], section 3.6. See [NCSF1], section 3.1 for the properties of this map.

See also:

omega involution of QSym, psi involution of NCSF, star involution of NCSF.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L(S[3,2].omega_involution())
L[2, 3]
sage: L(S[6,3].omega_involution())
L[3, 6]
sage: L(S[1,3].omega_involution())
L[3, 1]
sage: L((S[9,1] - S[8,2] + 2*S[6,4] - 3*S[3] + 4*S[[]]).omega_involution()) # long ti
4*L[] + L[1, 9] - L[2, 8] - 3*L[3] + 2*L[4, 6]
sage: L((S[3,3] - 2*S[2]).omega_involution())
-2*L[2] + L[3, 3]
sage: L(S([4,2]).omega_involution())
L[2, 4]
sage: R = NSym.R()
sage: R([4,2]).omega_involution()
R[1, 2, 1, 1, 1]
sage: R.zero().omega_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).omega_involution()
-Phi[1, 2]
sage: Psi = NSym.Psi()
sage: Psi([2,1]).omega_involution()
-Psi[1, 2]
sage: Psi([3,1]).omega_involution()
Psi[1, 3]
```

Testing the $\pi(\omega(f)) = \omega(\pi(f))$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).omega_involution().to_symmetric_function()
....:      == R(I).to_symmetric_function().omega_involution()
....:      for I in Compositions(4) )
True
```

The omega involution on $QSym$ is adjoint to the omega involution on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).omega_involution().duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).omega_involution())
....:           for I in Compositions(2) )
....:      for J in Compositions(3) )
True
```

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative

symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also:

`psi involution of QSym`, `star involution of NCSF`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,2].psi_involution()
R[1, 1, 2, 1]
sage: R[6,3].psi_involution()
R[1, 1, 1, 1, 1, 2, 1, 1]
sage: (R[9,1] - R[8,2] + 2*R[2,4] - 3*R[3] + 4*R[[]]).psi_involution()
4*R[] - 3*R[1, 1, 1] + R[1, 1, 1, 1, 1, 1, 1, 1, 2] - R[1, 1, 1, 1, 1, 1, 1, 2, 1] +
sage: (R[3,3] - 2*R[2]).psi_involution()
-2*R[1, 1] + R[1, 1, 2, 1, 1]
sage: R([2,1,1]).psi_involution()
R[1, 3]
sage: S = NSym.S()
sage: S([2,1]).psi_involution()
S[1, 1, 1] - S[2, 1]
sage: S.zero().psi_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).psi_involution()
-Phi[2, 1]
sage: Phi([3,1]).psi_involution()
Phi[3, 1]
```

The Psi basis doesn't behave as nicely:

```
sage: Psi = NSym.Psi()
sage: Psi([2,1]).psi_involution()
-Psi[2, 1]
sage: Psi([3,1]).psi_involution()
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

The involution ψ commutes with the antipode:

```
sage: all( R(I).psi_involution().antipode()
....:      == R(I).antipode().psi_involution()
....:      for I in Compositions(4) )
True
```

Testing the $\pi(\psi(f)) = \omega(\pi(f))$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).psi_involution().to_symmetric_function()
....:      == R(I).to_symmetric_function().omega()
....:      for I in Compositions(4) )
True
```

The involution ψ of $QSym$ is adjoint to the involution ψ of $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).psi_involution().duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).psi_involution())
....:           for I in Compositions(2) )
....:      for J in Compositions(3) )
True
```

star_involution()

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see `to_descent_algebra()`), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

`star involution of QSym`, `psi involution of NCSF`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].star_involution()
S[2, 3]
sage: S[6,3].star_involution()
S[3, 6]
sage: (S[9,1] - S[8,2] + 2*S[6,4] - 3*S[3] + 4*S[[]]).star_involution()
4*S[] + S[1, 9] - S[2, 8] - 3*S[3] + 2*S[4, 6]
```

```
sage: (S[3,3] - 2*S[2]).star_involution()
-2*S[2] + S[3, 3]
sage: S([4,2]).star_involution()
S[2, 4]
sage: R = NSym.R()
sage: R([4,2]).star_involution()
R[2, 4]
sage: R.zero().star_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

The Psi basis doesn't behave as nicely:

```
sage: Psi = NSym.Psi()
sage: Psi([2,1]).star_involution()
Psi[1, 2]
sage: Psi([3,1]).star_involution()
1/2*Psi[1, 1, 2] - 1/2*Psi[1, 2, 1] + Psi[1, 3]
```

The star involution commutes with the antipode:

```
sage: all( R(I).star_involution().antipode()
....:      == R(I).antipode().star_involution()
....:      for I in Compositions(4) )
True
```

Checking the relation with the descent algebra described above:

```
sage: def descent_test(n):
....:     DA = DescentAlgebra(QQ, n)
....:     NSym = NonCommutativeSymmetricFunctions(QQ)
....:     S = NSym.S()
....:     DAD = DA.D()
....:     w_n = DAD(set(range(1, n)))
....:     for I in Compositions(n):
....:         if not (S[I].star_involution()
....:                 == w_n * S[I].to_descent_algebra(n) * w_n):
....:             return False
....:         return True
sage: all( descent_test(i) for i in range(4) )
True
sage: all( descent_test(i) for i in range(6) ) # long time
True
```

Testing the $\pi(f^*) = \pi(f)$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).star_involution().to_symmetric_function()
....:      == R(I).to_symmetric_function()
....:      for I in Compositions(4) )
True
```

The star involution on $QSym$ is adjoint to the star involution on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
```

```
sage: all( all( M(I).star_involution().duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).star_involution())
....:           for I in Compositions(2) )
....:       for J in Compositions(3) )
True
```

to_descent_algebra(*n=None*)

Return the image of the `n`-th degree homogeneous component of `self` in the descent algebra of S_n over the same base ring as `self`.

This is based upon the canonical isomorphism from the n-th degree homogeneous component of the algebra of noncommutative symmetric functions to the descent algebra of S_n. This isomorphism maps the inner product of noncommutative symmetric functions either to the product in the descent algebra of S_n or to its opposite (depending on how the latter is defined).

If `n` is not specified, it will be taken to be the highest homogeneous component of `self`.

OUTPUT:

- The image of the `n`-th homogeneous component of `self` under the isomorphism into the descent algebra of S_n over the same base ring as `self`.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: S[2,1].to_descent_algebra(3)
B[2, 1]
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(4)
-3*B[1, 1, 2] + B[1, 2, 1]
sage: S[2,1].to_descent_algebra(2)
0
sage: S[2,1].to_descent_algebra()
B[2, 1]
sage: S.zero().to_descent_algebra().parent()
Descent algebra of 0 over Integer Ring in the subset basis
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(1)
0
```

to_ncsym()

Return the image of `self` in the symmetric functions in non-commuting variables under the map described in `to_ncsym_on_basis()`.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_ncsym()
2*m{} + 2*m{{1}} + 3/2*m{{1}, {2}}
sage: y = N.Phi()[1,2]
sage: y.to_ncsym()
m{{1}, {2, 3}} + m{{1, 2, 3}}
```

to_symmetric_function()

Return the commutative image of a non-commutative symmetric function.

OUTPUT:

- The commutative image of `self`. This will be a symmetric function.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
```

```
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

to_symmetric_group_algebra()

Return the image of a non-commutative symmetric function into the symmetric group algebra where the ribbon basis element indexed by a composition is associated with the sum of all permutations which have descent set equal to said composition. In compliance with the anti- isomorphism between the descent algebra and the non-commutative symmetric functions, we index descent positions by the reversed composition.

OUTPUT:

- The image of `self` under the embedding of the n-th degree homogeneous component of the non-commutative symmetric functions in the symmetric group algebra of S_n. This can behave unexpectedly when `self` is not homogeneous.

EXAMPLES:

```
sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sage: R[2,1].to_symmetric_group_algebra()
[1, 3, 2] + [2, 3, 1]
sage: R([]).to_symmetric_group_algebra()
[]
```

TESTS:

Sending a noncommutative symmetric function to the symmetric group algebra directly has the same result as going through the descent algebra:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: SGA4 = SymmetricGroupAlgebra(QQ, 4)
sage: D4 = DescentAlgebra(QQ, 4).D()
sage: all( S[C].to_symmetric_group_algebra()
....:      == SGA4(D4(S[C].to_descent_algebra(4)))
....:      for C in Compositions(4) )
True
```

verschiebung(n)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (`verschiebung()`) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also:

`frobenius method of QSym`, `verschiebung method of Sym`

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].verschiebung(2)
0
sage: S[6,4].verschiebung(2)
S[3, 2]
sage: (S[9,1] - S[8,2] + 2*S[6,4] - 3*S[3] + 4*S[[]]).verschiebung(2)
4*S[] + 2*S[3, 2] - S[4, 1]
sage: (S[3,3] - 2*S[2]).verschiebung(3)
S[1, 1]
sage: S([4,2]).verschiebung(1)
S[4, 2]
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( R(I).verschiebung(2).antipode()
....:      == R(I).antipode().verschiebung(2)
....:      for I in Compositions(4) )
True
```

They lift the Verschiebung operators of the ring of symmetric functions:

```
sage: all( S(I).verschiebung(2).to_symmetric_function()
....:      == S(I).to_symmetric_function().verschiebung(2)
....:      for I in Compositions(4) )
True
```

The Frobenius operators on $QSym$ are adjoint to the Verschiebung operators on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: all( all( M(I).frobenius(3).duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).verschiebung(3))
```

```
....:           for I in Compositions(2) )
....:       for J in Compositions(3) )
True
```

class NonCommutativeSymmetricFunctions.Bases.**ParentMethods**

immaculate_function(*xs*)

Return the immaculate function corresponding to the integer vector `xs`, written in the basis `self`.

If α is any integer vector – i.e., an element of $\mathbf{Z}^m$ for some $m \in \mathbf{N}$ –, the *immaculate function corresponding to* α is a non-commutative symmetric function denoted by $\mathfrak{S}_\alpha$. One way to define this function is by setting

$$\mathfrak{S}_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1+\sigma(1)-1} S_{\alpha_2+\sigma(2)-2} \cdots S_{\alpha_m+\sigma(m)-m},$$

where α is written in the form $(\alpha_1, \alpha_2, \ldots, \alpha_m)$, and where S stands for the complete basis (`Complete`).

The immaculate function $\mathfrak{S}_\alpha$ first appeared in [BBSSZ2012] (where it was defined differently, but the definition we gave above appeared as Theorem 3.27).

The immaculate functions $\mathfrak{S}_\alpha$ for α running over all compositions (i.e., finite sequences of positive integers) form a basis of $NCSF$. This is the *immaculate basis* (`Immaculate`).

INPUT:

- `xs` – list (or tuple or any iterable – possibly a composition) of integers

OUTPUT:

The immaculate function $\mathfrak{S}_{xs}$ written in the basis `self`.

EXAMPLES:

Let us first check that, for `xs` a composition, we get the same as the result of `self.realization_of().I()[xs]`:

```
sage: def test_comp(xs):
....:     NSym = NonCommutativeSymmetricFunctions(QQ)
....:     I = NSym.I()
....:     return I[xs] == I.immaculate_function(xs)
sage: def test_allcomp(n):
....:     return all( test_comp(c) for c in Compositions(n) )
sage: test_allcomp(1)
True
sage: test_allcomp(2)
True
sage: test_allcomp(3)
True
```

Now some examples of non-composition immaculate functions:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: I.immaculate_function([0, 1])
0
sage: I.immaculate_function([0, 2])
-I[1, 1]
sage: I.immaculate_function([-1, 1])
-I[]
sage: I.immaculate_function([2, -1])
0
```

```
sage: I.immaculate_function([2, 0])
I[2]
sage: I.immaculate_function([2, 0, 1])
0
sage: I.immaculate_function([1, 0, 2])
-I[1, 1, 1]
sage: I.immaculate_function([2, 0, 2])
-I[2, 1, 1]
sage: I.immaculate_function([0, 2, 0, 2])
I[1, 1, 1, 1] + I[1, 2, 1]
sage: I.immaculate_function([2, 0, 2, 0, 2])
I[2, 1, 1, 1, 1] + I[2, 1, 2, 1]
```

TESTS:

Basis-independence:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: L = NSym.L()
sage: S = NSym.S()
sage: L(S.immaculate_function([0, 2, 0, 2])) == L.immaculate_function([0, 2, 0, 2])
True
```

to_ncsym()

Morphism κ of `self` to the algebra of symmetric functions in non-commuting variables that for the natural maps $\chi : NCSym \to Sym$ and $\rho : NSym \to Sym$, we have $\chi \circ \kappa = \rho$.

This is constructed by extending the method `to_ncsym_on_basis()` linearly.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: R.to_ncsym(x)
2*m{} + 2*m{{1}} + 3/2*m{{1}, {2}}
sage: S = N.complete()
sage: S.to_ncsym(S[1,2])
1/2*m{{1}, {2}, {3}} + m{{1}, {2, 3}} + 1/2*m{{1, 2}, {3}}
 + m{{1, 2, 3}} + 1/2*m{{1, 3}, {2}}
sage: Phi = N.Phi()
sage: Phi.to_ncsym(Phi[1,3])
-1/4*m{{1}, {2}, {3, 4}} - 1/4*m{{1}, {2, 3}, {4}} + m{{1}, {2, 3, 4}}
 + 1/2*m{{1}, {2, 4}, {3}} - 1/4*m{{1, 2}, {3, 4}} - 1/4*m{{1, 2, 3}, {4}}
 + m{{1, 2, 3, 4}} + 1/2*m{{1, 2, 4}, {3}} + 1/2*m{{1, 3}, {2, 4}}
 - 1/4*m{{1, 3, 4}, {2}} - 1/4*m{{1, 4}, {2, 3}}
sage: R.to_ncsym
Generic morphism:
  From: Non-Commutative Symmetric Functions over the Rational Field in the Ribbon bas
  To:   Symmetric functions in non-commuting variables over the Rational Field in the
```

to_ncsym_on_basis(I)

The image of the basis element indexed by `I` under the map κ to the symmetric functions in non-commuting variables such that for the natural maps $\chi : NCSym \to Sym$ and $\rho : NSym \to Sym$, we have $\chi \circ \kappa = \rho$.

This default implementation does a change of basis and computes the image in the complete basis.

See also:

`to_ncsym_on_basis()`

INPUT:

- I – a composition

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.to_ncsym(S[2,1])
1/2*m{{1}, {2}, {3}} + 1/2*m{{1}, {2, 3}} + m{{1, 2}, {3}}
 + m{{1, 2, 3}} + 1/2*m{{1, 3}, {2}}
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.to_ncsym_on_basis(Composition([2,1]))
1/3*m{{1}, {2}, {3}} + 1/6*m{{1}, {2, 3}} + 2/3*m{{1, 2}, {3}} + 1/6*m{{1, 3}, {2}}
```

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the basis or by coercion to the complete basis.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: R.to_symmetric_function(x)
2*s[] + 2*s[1] + 3*s[1, 1]
sage: nM = N.Monomial()
sage: nM.to_symmetric_function(nM[3,1])
h[1, 1, 1, 1] - 7/2*h[2, 1, 1] + h[2, 2] + 7/2*h[3, 1] - 2*h[4]
```

to_symmetric_function_on_basis(*I*)

The image of the basis element indexed by `I` under the map to the symmetric functions.

This default implementation does a change of basis and computes the image in the complete basis.

INPUT:

- I – a composition

OUTPUT:

- The image of the non-commutative basis element of `self` indexed by the composition `I` under the map from non-commutative symmetric functions to the symmetric functions. This will be a symmetric function.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: I = N.Immaculate()
sage: I.to_symmetric_function(I[1,3])
-h[2, 2] + h[3, 1]
sage: I.to_symmetric_function(I[1,2])
0
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_basis([3,1,2])==Phi.to_symmetric_function(Phi[3,1,
True
sage: Phi.to_symmetric_function_on_basis([])
h[]
```

NonCommutativeSymmetricFunctions.Bases.**super_categories**()

Return the super categories of the category of bases of the non-commutative symmetric functions.

OUTPUT:

•list

TESTS:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.Bases().super_categories()
[Category of bases of Non-Commutative Symmetric Functions or Quasisymmetric functions ov
 Category of realizations of graded modules with internal product over Rational Field]
```

class NonCommutativeSymmetricFunctions.**Complete**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Complete basis.

The Complete basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(S^I)_I$. It is a multiplicative basis, and is connected to the elementary generators Λ_i of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function S_n for every nonnegative integer n by the power series identity

$$\sum_{k\geq 0} t^k S_k = \left(\sum_{k\geq 0} (-t)^k \Lambda_k\right)^{-1},$$

with Λ_0 denoting 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $S^{(i_1,i_2,\ldots,i_k)} = S_{i_1} S_{i_2} \cdots S_{i_k}$.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: S = NCSF.Complete(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: S.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
```

The following are aliases for this basis:

```
sage: NCSF.complete()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: NCSF.S()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the Complete basis.

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)} \Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also:

psi involution of NCSF, psi involution of QSym, star involution of NCSF.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: S[3,1].psi_involution()
S[1, 1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]
sage: L(S[3,1].psi_involution())
L[3, 1]
sage: S[[]].psi_involution()
S[]
sage: S[1,1].psi_involution()
S[1, 1]
sage: (S[2,1] - 2*S[2]).psi_involution()
-2*S[1, 1] + S[1, 1, 1] + 2*S[2] - S[2, 1]
```

The implementation at hand is tailored to the complete basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(S[I].psi_involution()) == R(S[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

NonCommutativeSymmetricFunctions.Complete.**dual**()

Return the dual basis to the complete basis of non-commutative symmetric functions. This is the Monomial basis of quasi-symmetric functions.

OUTPUT:

- The Monomial basis of quasi-symmetric functions.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

NonCommutativeSymmetricFunctions.Complete.**internal_product_on_basis**(*I*, *J*)

The internal product of two non-commutative symmetric complete functions.

See internal_product() for a thorough documentation of this operation.

INPUT:

- I, J – compositions

OUTPUT:

- The internal product of the complete non-commutative symmetric function basis elements indexed by I and J, expressed in the complete basis.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2],[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
```

```
sage: S.internal_product_on_basis([2,2],[1,2])
0
```

NonCommutativeSymmetricFunctions.Complete.**to_ncsym_on_basis**(*I*)

Return the image of the complete non-commutative symmetric function in the symmetric functions in non-commuting variables under the embedding $\mathcal{I}$ which fixes the symmetric functions.

This map is defined by

$$S_n \mapsto \sum_{A \vdash [n]} \frac{\lambda(A)!\lambda(A)^!}{n!} \mathbf{m}_A$$

and extended as an algebra homomorphism.

Note: A remark in [BRRZ08] makes it clear that the embedding of NCSF into NCSym that preserves the projection into the symmetric functions is not unique. While this seems to be a natural embedding, any set of algebraic generators can be sent to a set of free elements in NCSym is also an embedding.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.to_ncsym_on_basis(Composition([2]))
1/2*m{{1}, {2}} + m{{1, 2}}
sage: S.to_ncsym_on_basis(Composition([1,2,1]))
1/2*m{{1}, {2}, {3}, {4}} + 1/2*m{{1}, {2}, {3, 4}} + m{{1}, {2, 3}, {4}}
 + m{{1}, {2, 3, 4}} + 1/2*m{{1}, {2, 4}, {3}} + 1/2*m{{1, 2}, {3}, {4}}
 + 1/2*m{{1, 2}, {3, 4}} + m{{1, 2, 3}, {4}} + m{{1, 2, 3, 4}}
 + 1/2*m{{1, 2, 4}, {3}} + 1/2*m{{1, 3}, {2}, {4}} + 1/2*m{{1, 3}, {2, 4}}
 + 1/2*m{{1, 3, 4}, {2}} + 1/2*m{{1, 4}, {2}, {3}} + m{{1, 4}, {2, 3}}
sage: S.to_ncsym_on_basis(Composition([]))
m{}
```

TESTS:

Check that the image under $\mathcal{I}$ fixes the symmetric functions:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: mon = SymmetricFunctions(QQ).monomial()
sage: all(S[c].to_ncsym().to_symmetric_function() == S[c].to_symmetric_function()
....:     for i in range(5) for c in Compositions(i))
True
```

We also check that the $NCSym$ monomials agree on the homogeneous and complete basis:

```
sage: h = SymmetricFunctions(QQ).h()
sage: all(m.from_symmetric_function(h[i]) == S[i].to_ncsym() for i in range(6))
True
```

NonCommutativeSymmetricFunctions.Complete.**to_symmetric_function**()

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the complete basis.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[3,1,2])
```

```
h[3, 2, 1]
sage: S.to_symmetric_function(S[[]])
h[]
```

NonCommutativeSymmetricFunctions.Complete.**to_symmetric_function_on_basis**(*I*)

The commutative image of a complete element

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element and the output is in the complete basis of the symmetric functions.

INPUT:

- I – a composition

OUTPUT:

- The commutative image of the complete basis element indexed by I. The result is the complete symmetric function indexed by the partition obtained by sorting I.

EXAMPLES:

```
sage: S=NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.to_symmetric_function_on_basis([2,1,3])
h[3, 2, 1]
sage: S.to_symmetric_function_on_basis([])
h[]
```

class NonCommutativeSymmetricFunctions.**Elementary**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Elementary basis.

The Elementary basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Lambda^I)_I$. It is a multiplicative basis, and is obtained from the elementary generators Λ_i of the ring of non-commutative symmetric functions through the formula $\Lambda^{(i_1,i_2,\ldots,i_k)} = \Lambda_{i_1}\Lambda_{i_2}\cdots\Lambda_{i_k}$ for every composition $(i_1, i_2, \ldots, i_k)$.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: L = NCSF.Elementary(); L
Non-Commutative Symmetric Functions over the Rational Field in the Elementary basis
sage: L.an_element()
2*L[] + 2*L[1] + 3*L[1, 1]
```

The following are aliases for this basis:

```
sage: NCSF.elementary()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary basis
sage: NCSF.L()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary basis
```

class **Element**(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also:

`psi involution of NCSF`, `psi involution of QSym`, `star involution of NCSF`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L[3,1].psi_involution()
L[1, 1, 1, 1] - L[1, 2, 1] - L[2, 1, 1] + L[3, 1]
sage: S(L[3,1].psi_involution())
S[3, 1]
sage: L[[]].psi_involution()
L[]
sage: L[1,1].psi_involution()
L[1, 1]
sage: (L[2,1] - 2*L[2]).psi_involution()
-2*L[1, 1] + L[1, 1, 1] + 2*L[2] - L[2, 1]
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution()
....:      for I in Compositions(3) )
True
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

star_involution()

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see `to_descent_algebra()`), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

`star involution of NCSF`, `psi involution of NCSF`, `star involution of QSym`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L[3,3,2,3].star_involution()
L[3, 2, 3, 3]
sage: L[6,3,3].star_involution()
L[3, 3, 6]
sage: (L[1,9,1] - L[8,2] + 2*L[6,4] - 3*L[3] + 4*L[[]]).star_involution()
4*L[] + L[1, 9, 1] - L[2, 8] - 3*L[3] + 2*L[4, 6]
sage: (L[3,3] - 2*L[2]).star_involution()
-2*L[2] + L[3, 3]
sage: L([4,1]).star_involution()
L[1, 4]
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(L[I].star_involution()) == S(L[I]).star_involution()
....:      for I in Compositions(4) )
True
```

verschiebung(n)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$,

it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (`verschiebung()`) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also:

`verschiebung method of NCSF`, `frobenius method of QSym`, `verschiebung method of Sym`

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L([4,2]).verschiebung(2)
-L[2, 1]
sage: L([2,4]).verschiebung(2)
-L[1, 2]
sage: L([6]).verschiebung(2)
-L[3]
sage: L([2,1]).verschiebung(3)
0
sage: L([3]).verschiebung(2)
0
sage: L([]).verschiebung(2)
L[]
sage: L([5, 1]).verschiebung(3)
0
sage: L([5, 1]).verschiebung(6)
0
sage: L([5, 1]).verschiebung(2)
0
sage: L([1, 2, 3, 1]).verschiebung(7)
0
sage: L([7]).verschiebung(7)
L[1]
sage: L([1, 2, 3, 1]).verschiebung(5)
0
sage: (L[1] - L[2] + 2*L[3]).verschiebung(1)
L[1] - L[2] + 2*L[3]
```

TESTS:

The current implementation on the Elementary basis gives the same results as the default implementation:

```
sage: S = NSym.S()
sage: def test_L(N, n):
....:     for I in Compositions(N):
....:         if S(L[I].verschiebung(n)) != S(L[I]).verschiebung(n):
....:             return False
....:     return True
sage: test_L(4, 2)
True
sage: test_L(6, 2)
True
sage: test_L(6, 3)
True
sage: test_L(8, 4)      # long time
True
```

class NonCommutativeSymmetricFunctions.**Immaculate**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The immaculate basis of the non-commutative symmetric functions.

The immaculate basis first appears in Berg, Bergeron, Saliola, Serrano and Zabrocki's [BBSSZ2012]. It can be described as the family $(\mathfrak{S}_\alpha)$, where α runs over all compositions, and $\mathfrak{S}_\alpha$ denotes the immaculate function corresponding to α (see immaculate_function()).

If α is a composition $(\alpha_1, \alpha_2, \ldots, \alpha_m)$, then

$$\mathfrak{S}_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1+\sigma(1)-1} S_{\alpha_2+\sigma(2)-2} \cdots S_{\alpha_m+\sigma(m)-m}.$$

Warning: This *basis* contains only the immaculate functions indexed by compositions (i.e., finite sequences of positive integers). To obtain the remaining immaculate functions (sensu lato), use the immaculate_function() method. Calling the immaculate *basis* with a list which is not a composition will currently return garbage!

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: I = NCSF.I()
sage: I([1,3,2])*I([1])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
sage: I([1])*I([1,3,2])
I[1, 1, 3, 2] - I[2, 2, 1, 2] - I[2, 2, 2, 1] - I[2, 2, 3] - I[3, 2, 2]
sage: I([1,3])*I([1,1])
I[1, 3, 1, 1] + I[1, 4, 1] + I[2, 3, 1] + I[2, 4]
sage: I([3,1])*I([2,1])
I[3, 1, 2, 1] + I[3, 2, 1, 1] + I[3, 2, 2] + I[3, 3, 1] + I[4, 1, 1, 1] + I[4, 1, 2] + 2*I[4
sage: R = NCSF.ribbon()
sage: I(R[1,3,1])
I[1, 3, 1] + I[2, 2, 1] + I[2, 3] + I[3, 1, 1] + I[3, 2]
sage: R(I(R([2,1,3])))
R[2, 1, 3]
```

class **Element**(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the Immaculate basis.

bernstein_creation_operator(n)

Return the image of `self` under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator $\mathbb{B}_n$ is defined as the endomorphism of the space $NSym$ of noncommutative symmetric functions given by

$$\mathbb{B}_n I_{(\alpha_1,\alpha_2,\ldots,\alpha_m)} = I_{(n,\alpha_1,\alpha_2,\ldots,\alpha_m)},$$

where $I_{(\alpha_1,\alpha_2,\ldots,\alpha_m)}$ is the immaculate function associated to the m-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_m) \in \mathbf{Z}^m$.

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions.

For more information on the n-th Bernstein creation operator, see `bernstein_creation_operator()`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: b = I[1,3,2,1]
sage: b.bernstein_creation_operator(3)
I[3, 1, 3, 2, 1]
sage: b.bernstein_creation_operator(5)
I[5, 1, 3, 2, 1]
sage: elt = b + 3*I[4,1,2]
sage: elt.bernstein_creation_operator(1)
I[1, 1, 3, 2, 1] + 3*I[1, 4, 1, 2]
```

We check that this agrees with the definition on the Complete basis:

```
sage: S = NSym.S()
sage: S(elt).bernstein_creation_operator(1) == S(elt.bernstein_creation_operator(1))
True
```

Check on non-positive values of n:

```
sage: I[2,2,2].bernstein_creation_operator(-1)
I[1, 1, 1, 2] + I[1, 1, 2, 1] + I[1, 2, 1, 1] - I[1, 2, 2]
sage: I[2,3,2].bernstein_creation_operator(0)
-I[1, 1, 3, 2] - I[1, 2, 2, 2] - I[1, 2, 3, 1] + I[2, 3, 2]
```

NonCommutativeSymmetricFunctions.Immaculate.**dual**()

Return the dual basis to the Immaculate basis of NCSF.

The basis returned is the dualImmaculate basis of QSym.

OUTPUT:

- The dualImmaculate basis of the quasi-symmetric functions.

EXAMPLES:

```
sage: I=NonCommutativeSymmetricFunctions(QQ).Immaculate()
sage: I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate
basis
```

class NonCommutativeSymmetricFunctions.**Monomial**(*NCSF*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

The monomial basis defined in Tevlin's paper [Tev2007].

The monomial basis is well-defined only when the base ring is a $\mathbf{Q}$-algebra. It is the basis denoted by $(M^I)_I$ in [Tev2007].

TESTS:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: nM = NCSF.monomial(); nM
Non-Commutative Symmetric Functions over the Rational Field in the Monomial basis
sage: nM([1,1])*nM([2])
3*nM[1, 1, 2] + nM[1, 3] + nM[2, 2]
sage: R = NCSF.ribbon()
sage: nM(R[1,3,1])
11*nM[1, 1, 1, 1, 1] + 8*nM[1, 1, 2, 1] + 8*nM[1, 2, 1, 1] + 5*nM[1, 3, 1] + 8*nM[2, 1, 1, 1
```

class NonCommutativeSymmetricFunctions.**MultiplicativeBases**(*parent_with_realization*)

Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases of non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBases()
Category of multiplicative bases of Non-Commutative Symmetric Functions over the Rational Fi
```

The complete basis is a multiplicative basis, but the ribbon basis is not:

```
sage: N.Complete() in N.MultiplicativeBases()
True
sage: N.Ribbon() in N.MultiplicativeBases()
False
```

class ParentMethods

algebra_generators()

Return the algebra generators of a given multiplicative basis of non-commutative symmetric functions.

OUTPUT:

- The family of generators of the multiplicative basis self.

EXAMPLES:

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: f = Psi.algebra_generators()
sage: f
Lazy family (<lambda>(i))_{i in Positive integers}
sage: f[1], f[2], f[3]
(Psi[1], Psi[2], Psi[3])
```

algebra_morphism(*on_generators*, ***keywords*)

Given a map defined on the generators of the multiplicative basis self, return the algebra morphism that extends this map to the whole algebra of non-commutative symmetric functions.

INPUT:

- on_generators – a function defined on the index set of the generators (that is, on the positive integers)
- anti – a boolean; defaults to False
- category – a category; defaults to None

OUTPUT:

- The algebra morphism of self which is defined by on_generators in the basis self.

When `anti` is set to `True`, an algebra anti-morphism is computed instead of an algebra morphism.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi()
sage: double = lambda i: Psi[i,i]
sage: f = Psi.algebra_morphism(double, codomain = Psi)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field i
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] + 3*Psi[1, 1, 3, 3, 2, 2] + Psi[2, 2, 4, 4]
sage: f.category()
Category of endsets of unital magmas and right modules over Rational Field and left m
```

When extra properties about the morphism are known, one can specify the category of which it is a morphism:

```
sage: negate = lambda i: -Psi[i]
sage: f = Psi.algebra_morphism(negate, codomain = Psi, category = GradedHopfAlgebrasW
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field i
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] - 3*Psi[1, 3, 2] + Psi[2, 4]
sage: f.category()
Category of endsets of hopf algebras over Rational Field and graded modules over Rati
```

If `anti` is true, this returns an anti-algebra morphism:

```
sage: f = Psi.algebra_morphism(double, codomain = Psi, anti=True)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field i
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] + 3*Psi[2, 2, 3, 3, 1, 1] + Psi[4, 4, 2, 2]
sage: f.category()
Category of endsets of modules with basis over Rational Field
```

antipode()

Return the antipode morphism on the basis `self`.

The antipode of $NSym$ is closely related to the omega involution; see `omega_involution()` for the latter.

OUTPUT:

•The antipode module map from non-commutative symmetric functions on basis `self`.

EXAMPLES:

```
sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field i
```

coproduct()

Return the coproduct morphism in the basis `self`.

OUTPUT:

•The coproduct module map from non-commutative symmetric functions on basis `self`.

EXAMPLES:

```
sage: S=NonCommutativeSymmetricFunctions(QQ).S()
sage: S.coproduct
Generic morphism:
  From: Non-Commutative Symmetric Functions over the Rational Field in the Complete b
  To:   Non-Commutative Symmetric Functions over the Rational Field in the Complete b
```

product_on_basis(*composition1*, *composition2*)

Return the product of two basis elements from the multiplicative basis. Multiplication is just concatenation on compositions.

INPUT:

- `composition1`, `composition2` – integer compositions

OUTPUT:

- The product of the two non-commutative symmetric functions indexed by `composition1` and `composition2` in the multiplicative basis `self`. This will be again a non-commutative symmetric function.

EXAMPLES:

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi[3,1,2] * Psi[4,2] == Psi[3,1,2,4,2]
True
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.product_on_basis(Composition([2,1]), Composition([1,2]))
S[2, 1, 1, 2]
```

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the algebra morphism by the image of the generators.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[1,3])
h[3, 1]
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function(Phi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function(Psi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

to_symmetric_function_on_generators(*i*)

Morphism of the generators to symmetric functions.

This is constructed by coercion to the complete basis and applying the morphism.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: Phi.to_symmetric_function_on_generators(0)
h[]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: L = N.elementary()
sage: L.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 2*h[2, 1] + h[3]
```

NonCommutativeSymmetricFunctions.MultiplicativeBases.**super_categories**()
Return the super categories of the category of multiplicative bases of the non-commutative symmetric functions.

OUTPUT:
- list

TESTS:
```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBases().super_categories()
[Category of bases of Non-Commutative Symmetric Functions over the Rational Field]
```

class NonCommutativeSymmetricFunctions.**MultiplicativeBasesOnGroupLikeElements**(*parent_with_re*
Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases on grouplike elements of non-commutative symmetric functions.

Here, a "multiplicative basis on grouplike elements" means a multiplicative basis whose generators $(f_1, f_2, f_3, \ldots)$ satisfy

$$\Delta(f_i) = \sum_{j=0}^{i} f_j \otimes f_{i-j}$$

with $f_0 = 1$. (In other words, the generators are to form a divided power sequence in the sense of a coalgebra.) This does not mean that the generators are grouplike, but means that the element $1 + f_1 + f_2 + f_3 + \cdots$ in the completion of the ring of non-commutative symmetric functions with respect to the grading is grouplike.

EXAMPLES:
```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative Symmetric Functio
```

The complete basis is a multiplicative basis, but the ribbon basis is not:
```
sage: N.Complete() in N.MultiplicativeBasesOnGroupLikeElements()
True
sage: N.Ribbon() in N.MultiplicativeBasesOnGroupLikeElements()
False
```

class ParentMethods

antipode_on_basis(*composition*)
Return the application of the antipode to a basis element.

INPUT:
- composition – a composition

OUTPUT:
- The image of the basis element indexed by composition under the antipode map.

EXAMPLES:
```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.antipode_on_basis(Composition([2,1]))
-S[1, 1, 1] + S[1, 2]
sage: S[1].antipode() # indirect doctest
-S[1]
sage: S[2].antipode() # indirect doctest
S[1, 1] - S[2]
sage: S[3].antipode() # indirect docttest
```

```
-S[1, 1, 1] + S[1, 2] + S[2, 1] - S[3]
sage: S[2,3].coproduct().apply_multilinear_morphism(lambda be,ga: S(be)*S(ga).antipod
0
sage: S[2,3].coproduct().apply_multilinear_morphism(lambda be,ga: S(be).antipode()*S(
0
```

coproduct_on_generators(*i*)

Return the image of the i^{th} generator of the algebra under the coproduct.

INPUT:

- `i` – a positive integer

OUTPUT:

- The result of applying the coproduct to the i^{th} generator of `self`.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.coproduct_on_generators(3)
S[] # S[3] + S[1] # S[2] + S[2] # S[1] + S[3] # S[]
```

TESTS:

```
sage: S.coproduct_on_generators(0)
Traceback (most recent call last):
...
ValueError: Not a positive integer: 0
```

NonCommutativeSymmetricFunctions.MultiplicativeBasesOnGroupLikeElements.**super_categ**

Return the super categories of the category of multiplicative bases of group-like elements of the non-commutative symmetric functions.

OUTPUT:

- list

TESTS:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnGroupLikeElements().super_categories()
[Category of multiplicative bases of Non-Commutative Symmetric Functions over the Ration
```

class NonCommutativeSymmetricFunctions.**MultiplicativeBasesOnPrimitiveElements**(*parent_with_re*

Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases of the non-commutative symmetric functions whose generators are primitive elements.

An element x of a bialgebra is *primitive* if $\Delta(x) = x \otimes 1 + 1 \otimes x$, where Δ is the coproduct of the bialgebra.

Given a multiplicative basis and knowing the coproducts and antipodes of its generators, one can compute the coproduct and the antipode of any element, since they are respectively algebra morphisms and anti-morphisms. See `antipode_on_generators()` and `coproduct_on_generators()`.

Todo

this could be generalized to any free algebra.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnPrimitiveElements()
Category of multiplicative bases on primitive elements of Non-Commutative Symmetric Functio
```

The Phi and Psi bases are multiplicative bases whose generators are primitive elements, but the complete and ribbon bases are not:

```
sage: N.Phi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Psi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Complete() in N.MultiplicativeBasesOnPrimitiveElements()
False
sage: N.Ribbon() in N.MultiplicativeBasesOnPrimitiveElements()
False
```

class ParentMethods

antipode_on_generators(i)

Return the image of a generator of a primitive basis of the non-commutative symmetric functions under the antipode map.

INPUT:

- `i` – a positive integer

OUTPUT:

- The image of the i-th generator of the multiplicative basis `self` under the antipode of the algebra of non-commutative symmetric functions.

EXAMPLES:

```
sage: Psi=NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.antipode_on_generators(2)
-Psi[2]
```

TESTS:

```
sage: Psi.antipode_on_generators(0)
Traceback (most recent call last):
...
ValueError: Not a positive integer: 0
```

coproduct_on_generators(i)

Return the image of the i^{th} generator of the multiplicative basis `self` under the coproduct.

INPUT:

- `i` – a positive integer

OUTPUT:

- The result of applying the coproduct to the i^{th} generator of `self`.

EXAMPLES:

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.coproduct_on_generators(3)
Psi[] # Psi[3] + Psi[3] # Psi[]
```

TESTS:

```
sage: Psi.coproduct_on_generators(0)
Traceback (most recent call last):
...
ValueError: Not a positive integer: 0
```

NonCommutativeSymmetricFunctions.MultiplicativeBasesOnPrimitiveElements.**super_categ**

Return the super categories of the category of multiplicative bases of primitive elements of the non-commutative symmetric functions.

OUTPUT:

- list

TESTS:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnPrimitiveElements().super_categories()
[Category of multiplicative bases of Non-Commutative Symmetric Functions over the Rationa
```

class NonCommutativeSymmetricFunctions.**Phi**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Phi basis.

The Phi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Phi^I)_I$. It is a multiplicative basis, and is connected to the elementary generators Λ_i of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function Φ_n for every positive integer n by the power series identity

$$\sum_{k\geq 1} t^k \frac{1}{k}\Phi_k = -\log\left(\sum_{k\geq 0}(-t)^k\Lambda_k\right),$$

with Λ_0 denoting 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $\Phi^{(i_1,i_2,\ldots,i_k)} = \Phi_{i_1}\Phi_{i_2}\cdots\Phi_{i_k}$.

The Φ-basis is well-defined only when the base ring is a $\mathbf{Q}$-algebra. The elements of the Φ-basis are known as the "power-sum non-commutative symmetric functions of the second kind".

The generators Φ_n are related to the (first) Eulerian idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.4 for details).

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
sage: Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

psi_involution()

Return the image of the noncommutative symmetric function self under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and

R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also:

psi involution of NCSF, psi involution of QSym, star involution of NCSF.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,2].psi_involution()
-Phi[3, 2]
sage: Phi[2,2].psi_involution()
Phi[2, 2]
sage: Phi[[]].psi_involution()
Phi[]
sage: (Phi[2,1] - 2*Phi[2]).psi_involution()
2*Phi[2] - Phi[2, 1]
sage: Phi(0).psi_involution()
0
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

star_involution()

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see to_descent_algebra()), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

`star involution of NCSF`, `psi involution of NCSF`, `star involution of QSym`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,1,1,4].star_involution()
Phi[4, 1, 1, 3]
sage: Phi[4,2,1].star_involution()
Phi[1, 2, 4]
sage: (Phi[1,4] - Phi[2,3] + 2*Phi[5,4] - 3*Phi[3] + 4*Phi[[]]).star_involution()
4*Phi[] - 3*Phi[3] - Phi[3, 2] + Phi[4, 1] + 2*Phi[4, 5]
sage: (Phi[3,3] + 3*Phi[1]).star_involution()
3*Phi[1] + Phi[3, 3]
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(Phi[I].star_involution()) == S(Phi[I]).star_involution()
....:      for I in Compositions(4) )
True
```

verschiebung(*n*)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (`verschiebung()`) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also:

`verschiebung method of NCSF`, `frobenius method of QSym`, `verschiebung method of Sym`

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: Phi = NSym.Phi()
sage: Phi([4,2]).verschiebung(2)
4*Phi[2, 1]
sage: Phi([2,4]).verschiebung(2)
4*Phi[1, 2]
sage: Phi([6]).verschiebung(2)
2*Phi[3]
sage: Phi([2,1]).verschiebung(3)
0
sage: Phi([3]).verschiebung(2)
0
sage: Phi([]).verschiebung(2)
Phi[]
sage: Phi([5, 1]).verschiebung(3)
0
sage: Phi([5, 1]).verschiebung(6)
0
sage: Phi([5, 1]).verschiebung(2)
0
sage: Phi([1, 2, 3, 1]).verschiebung(7)
0
sage: Phi([7]).verschiebung(7)
7*Phi[1]
sage: Phi([1, 2, 3, 1]).verschiebung(5)
0
sage: (Phi[1] - Phi[2] + 2*Phi[3]).verschiebung(1)
Phi[1] - Phi[2] + 2*Phi[3]
```

TESTS:

The current implementation on the Phi basis gives the same results as the default implementation:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: Phi = NSym.Phi()
sage: def test_phi(N, n):
....:     for I in Compositions(N):
....:         if S(Phi[I].verschiebung(n)) != S(Phi[I]).verschiebung(n):
....:             return False
....:     return True
sage: test_phi(4, 2)
```

```
True
sage: test_phi(6, 2)
True
sage: test_phi(6, 3)
True
sage: test_phi(8, 4)      # long time
True
```

class NonCommutativeSymmetricFunctions.**Psi**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Psi basis.

The Psi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Psi^I)_I$. It is a multiplicative basis, and is connected to the elementary generators Λ_i of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function Ψ_n for every positive integer n by the power series identity

$$\frac{d}{dt}\sigma(t) = \sigma(t) \cdot \left(\sum_{k \geq 1} t^{k-1} \Psi_k \right),$$

where

$$\sigma(t) = \left(\sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1}$$

and where Λ_0 denotes 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $\Psi^{(i_1,i_2,\ldots,i_k)} = \Psi_{i_1} \Psi_{i_2} \cdots \Psi_{i_k}$.

The Ψ-basis is a basis only when the base ring is a $\mathbf{Q}$-algebra (although the Ψ^I can be defined over any base ring). The elements of the Ψ-basis are known as the "power-sum non-commutative symmetric functions of the first kind". The generators Ψ_n correspond to the Dynkin (quasi-)idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.2 for details).

Another (equivalent) definition of Ψ_n is

$$\Psi_n = \sum_{i=0}^{n-1} (-1)^i R_{1^i, n-i},$$

where R denotes the ribbon basis of $NCSF$, and where 1^i stands for i repetitions of the integer 1.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi(); Psi
Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

Checking the equivalent definition of Ψ_n:

```
sage: def test_psi(n):
....:     NCSF = NonCommutativeSymmetricFunctions(ZZ)
....:     R = NCSF.R()
....:     Psi = NCSF.Psi()
....:     a = R.sum([(-1) ** i * R[[1]*i + [n-i]]
....:                for i in range(n)])
....:     return a == R(Psi[n])
```

```
sage: test_psi(2)
True
sage: test_psi(3)
True
sage: test_psi(4)
True
```

class Element(M, x)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

verschiebung(n)

Return the image of the noncommutative symmetric function self under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (verschiebung()) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $\underbrace{(n, n, \ldots, n)}_{|I|/n \text{ times}}$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also:

verschiebung method of NCSF, frobenius method of QSym, verschiebung method of Sym

INPUT:
- n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: Psi = NSym.Psi()
sage: Psi([4,2]).verschiebung(2)
4*Psi[2, 1]
sage: Psi([2,4]).verschiebung(2)

0
sage: (Psi[1] - Psi[2] + 2*Psi[3]).verschiebung(1)
Psi[1] - Psi[2] + 2*Psi[3]
```

TESTS:

The current implementation on the Psi basis gives the same results as the default implementation:

```
sage: S = NSym.S()
sage: def test_psi(N, n):
....:     for I in Compositions(N):
....:         if S(Psi[I].verschiebung(n)) != S(Psi[I]).verschiebung(n):
....:             return False
....:     return True
sage: test_psi(4, 2)
True
sage: test_psi(6, 2)
True
sage: test_psi(6, 3)
True
sage: test_psi(8, 4)      # long time
True
```

NonCommutativeSymmetricFunctions.Psi.**internal_product_on_basis_by_bracketing**(*I*, *J*)

The internal product of two elements of the Psi basis.

See `internal_product()` for a thorough documentation of this operation.

This is an implementation using [NCSF2] Lemma 3.10. It is fast when the length of I is small, but can get very slow otherwise. Therefore it is not being used by default for internally multiplying Psi functions.

INPUT:

- I, J – compositions

OUTPUT:

- The internal product of the elements of the Psi basis of $NSym$ indexed by I and J, expressed in the Psi basis.

AUTHORS:

- Travis Scrimshaw, 29 Mar 2014

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = N.Psi()
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[2,1,1])
4*Psi[1, 2, 1]
sage: Psi.internal_product_on_basis_by_bracketing([2,1,1],[1,2,1])
4*Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [1,1,1,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([3,1], [1,2,1])
-Psi[1, 2, 1] + Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [3,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2])
0
sage: Psi.internal_product_on_basis_by_bracketing([4], [1,2,1])
-Psi[1, 1, 2] + 2*Psi[1, 2, 1] - Psi[2, 1, 1]
```

TESTS:

The internal product computed by this method is identical with the one obtained by coercion to the complete basis:

```
sage: S = N.S()
sage: def psi_int_test(n):
....:     for I in Compositions(n):
....:         for J in Compositions(n):
....:             a = S(Psi.internal_product_on_basis_by_bracketing(I, J))
....:             b = S(Psi[I]).internal_product(S(Psi[J]))
....:             if a != b:
....:                 return False
....:     return True
sage: all( psi_int_test(i) for i in range(4) )
True
sage: psi_int_test(4)   # long time
True
sage: psi_int_test(5)   # long time
True
```

class NonCommutativeSymmetricFunctions.**Ribbon**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of non-commutative symmetric functions in the Ribbon basis.

The Ribbon basis is defined in Definition 3.12 of [NCSF1], where it is denoted by $(R_I)_I$. It is connected to the complete basis of the ring of non-commutative symmetric functions by the following relation: For

every composition I, we have

$$R_I = \sum_J (-1)^{\ell(I)-\ell(J)} S^J,$$

where the sum is over all compositions J which are coarser than I and $\ell(I)$ denotes the length of I. (See the proof of Proposition 4.13 in [NCSF1].)

The elements of the Ribbon basis are commonly referred to as the ribbon Schur functions.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: R = NCSF.Ribbon(); R
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
sage: R.an_element()
2*R[] + 2*R[1] + 3*R[1, 1]
```

The following are aliases for this basis:

```
sage: NCSF.ribbon()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
sage: NCSF.R()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
```

class Element(M, x)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

star_involution()

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see to_descent_algebra()), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

`star involution of NCSF`, `star involution of QSym`, `psi involution of NCSF`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,1,4,2].star_involution()
R[2, 4, 1, 3]
sage: R[4,1,2].star_involution()
R[2, 1, 4]
sage: (R[1] - R[2] + 2*R[5,4] - 3*R[3] + 4*R[[]]).star_involution()
4*R[] + R[1] - R[2] - 3*R[3] + 2*R[4, 5]
sage: (R[3,3] - 21*R[1]).star_involution()
-21*R[1] + R[3, 3]
sage: R([14,1]).star_involution()
R[1, 14]
```

The implementation at hand is tailored to the ribbon basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(R[I].star_involution()) == S(R[I]).star_involution()
....:      for I in Compositions(4) )
True
```

verschiebung(*n*)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (`verschiebung()`) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also:

`verschiebung method of NCSF`, `frobenius method of QSym`, `verschiebung method of Sym`

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
sage: R([2,1]).verschiebung(3)
-R[1]
sage: R([3]).verschiebung(2)
0
sage: R([]).verschiebung(2)
R[]
sage: R([5, 1]).verschiebung(3)
-R[2]
sage: R([5, 1]).verschiebung(6)
-R[1]
sage: R([5, 1]).verschiebung(2)
-R[3]
sage: R([1, 2, 3, 1]).verschiebung(7)
-R[1]
sage: R([1, 2, 3, 1]).verschiebung(5)
0
sage: (R[1] - R[2] + 2*R[3]).verschiebung(1)
R[1] - R[2] + 2*R[3]
```

TESTS:

The current implementation on the ribbon basis gives the same results as the default implementation:

```
sage: S = NSym.S()
sage: def test_ribbon(N, n):
....:     for I in Compositions(N):
....:         if S(R[I].verschiebung(n)) != S(R[I]).verschiebung(n):
....:             return False
....:     return True
sage: test_ribbon(4, 2)
True
sage: test_ribbon(6, 2)
True
sage: test_ribbon(6, 3)
True
sage: test_ribbon(8, 4)      # long time
True
```

NonCommutativeSymmetricFunctions.Ribbon.**antipode_on_basis**(*composition*)

Return the application of the antipode to a basis element of the ribbon basis `self`.

INPUT:

- `composition` – a composition

OUTPUT:

- The image of the basis element indexed by `composition` under the antipode map.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.antipode_on_basis(Composition([2,1]))
-R[2, 1]
sage: R[3,1].antipode() # indirect doctest
R[2, 1, 1]
sage: R[[]].antipode() # indirect doctest
R[]
```

We check that the implementation of the antipode at hand does not contradict the generic one:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: all( S(R[I].antipode()) == S(R[I]).antipode()
....:      for I in Compositions(4) )
True
```

NonCommutativeSymmetricFunctions.Ribbon.**dual**()

Return the dual basis to the ribbon basis of the non-commutative symmetric functions. This is the Fundamental basis of the quasi-symmetric functions.

OUTPUT:

- The fundamental basis of the quasi-symmetric functions.

EXAMPLES:

```
sage: R=NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.dual()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

NonCommutativeSymmetricFunctions.Ribbon.**product_on_basis**(*I*, *J*)

Return the product of two ribbon basis elements of the non-commutative symmetric functions.

INPUT:

- `I`, `J` – compositions

OUTPUT:

- The product of the ribbon functions indexed by `I` and `J`.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R[1,2,1] * R[3,1]
R[1, 2, 1, 3, 1] + R[1, 2, 4, 1]
sage: ( R[1,2] + R[3] ) * ( R[3,1] + R[1,2,1] )
R[1, 2, 1, 2, 1] + R[1, 2, 3, 1] + R[1, 3, 2, 1] + R[1, 5, 1] + R[3, 1, 2, 1] + R[3, 3,
```

TESTS:

```
sage: R[[]] * R[3,1]
R[3, 1]
sage: R[1,2,1] * R[[]]
R[1, 2, 1]
sage: R.product_on_basis(Composition([2,1]), Composition([1]))
R[2, 1, 1] + R[2, 2]
```

NonCommutativeSymmetricFunctions.Ribbon.**to_symmetric_function_on_basis**(*I*)

Return the commutative image of a ribbon basis element of the non-commutative symmetric functions.

INPUT:

- I – a composition

OUTPUT:

- The commutative image of the ribbon basis element indexed by I. This will be expressed as a symmetric function in the Schur basis.

EXAMPLES:

```
sage: R=NonCommutativeSymmetricFunctions(QQ).R()
sage: R.to_symmetric_function_on_basis(Composition([3,1,1]))
s[3, 1, 1]
sage: R.to_symmetric_function_on_basis(Composition([4,2,1]))
s[4, 2, 1] + s[5, 1, 1] + s[5, 2]
sage: R.to_symmetric_function_on_basis(Composition([]))
s[]
```

NonCommutativeSymmetricFunctions.**a_realization**()

Gives a realization of the algebra of non-commutative symmetric functions. This particular realization is the complete basis of non-commutative symmetric functions.

OUTPUT:

- The realization of the non-commutative symmetric functions in the complete basis.

EXAMPLES:

```
sage: NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete basis
```

NonCommutativeSymmetricFunctions.**dual**()

Return the dual to the non-commutative symmetric functions.

OUTPUT:

- The dual of the non-commutative symmetric functions over a ring. This is the algebra of quasi-symmetric functions over the ring.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF.dual()
Quasisymmetric functions over the Rational Field
```

class NonCommutativeSymmetricFunctions.**dualQuasisymmetric_Schur**(*NCSF*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The basis of NCSF dual to the Quasisymmetric-Schur basis of QSym.

The Quasisymmetric_Schur functions are defined in [QSCHUR] (see also Definition 5.1.1 of [LMvW13]). The dual basis in the algebra of non-commutative symmetric functions is defined by the following formula:

$$R_\alpha = \sum_T dQS_{shape(T)},$$

where the sum is over all standard composition tableaux with descent composition equal to α. The Quasisymmetric_Schur basis QS_α has the property that

$$s_\lambda = \sum_{sort(\alpha)=\lambda} QS_\alpha.$$

As a consequence the commutative image of a dual Quasisymmetric-Schur element in the algebra of symmetric functions (the map defined in the method to_symmetric_function()) is equal to the Schur function indexed by the decreasing sort of the indexing composition.

See also:

CompositionTableaux, CompositionTableau.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dQS = NCSF.dQS()
sage: dQS([1,3,2])*dQS([1])
dQS[1, 2, 4] + dQS[1, 3, 2, 1] + dQS[1, 3, 3] + dQS[3, 2, 2]
sage: dQS([1])*dQS([1,3,2])
dQS[1, 1, 3, 2] + dQS[1, 3, 3] + dQS[1, 4, 2] + dQS[2, 3, 2]
sage: dQS([1,3])*dQS([1,1])
dQS[1, 3, 1, 1] + dQS[1, 4, 1] + dQS[3, 2, 1] + dQS[4, 2]
sage: dQS([3,1])*dQS([2,1])
dQS[1, 1, 4, 1] + dQS[1, 4, 2] + dQS[1, 5, 1] + dQS[2, 4, 1] + dQS[3, 1,
2, 1] + dQS[3, 2, 2] + dQS[3, 3, 1] + dQS[4, 3] + dQS[5, 2]
sage: dQS([1,1]).coproduct()
dQS[] # dQS[1, 1] + dQS[1] # dQS[1] + dQS[1, 1] # dQS[]
sage: dQS([3,3]).coproduct().monomial_coefficients()[(Composition([1,2]),Composition([1,2]))
-1
sage: S = NCSF.complete()
sage: dQS(S[1,3,1])
dQS[1, 3, 1] + dQS[1, 4] + dQS[3, 2] + dQS[4, 1] + dQS[5]
sage: S(dQS[1,3,1])
S[1, 3, 1] - S[3, 2] - S[4, 1] + S[5]
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dQS([2,1,3])).to_symmetric_function())
s[3, 2, 1]
```

dual()

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the Quasisymmetric_Schur basis of QSym.

OUTPUT:

- the Quasisymmetric-Schur basis of the quasi-symmetric functions

EXAMPLES:

```
sage: dQS=NonCommutativeSymmetricFunctions(QQ).dualQuasisymmetric_Schur()
sage: dQS.dual()
Quasisymmetric functions over the Rational Field in the Quasisymmetric
Schur basis
sage: dQS.duality_pairing_matrix(dQS.dual(),3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

to_symmetric_function_on_basis(*I*)

The commutative image of a dual quasi-symmetric Schur element

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:

- I – a composition

OUTPUT:

- The commutative image of the dual quasi-Schur basis element indexed by I. The result is the Schur symmetric function indexed by the partition obtained by sorting I.

EXAMPLES:

```
sage: dQS=NonCommutativeSymmetricFunctions(QQ).dQS()
sage: dQS.to_symmetric_function_on_basis([2,1,3])
s[3, 2, 1]
sage: dQS.to_symmetric_function_on_basis([])
s[]
```

5.1.130 Quasisymmetric functions

class sage.combinat.ncsf_qsym.qsym.**QuasiSymmetricFunctions**(R)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The Hopf algebra of quasisymmetric functions.

Let R be a commutative ring with unity. The R-algebra of quasi-symmetric functions may be realized as an R-subalgebra of the ring of power series in countably many variables $R[[x_1, x_2, x_3, \ldots]]$. It consists of those formal power series p which are degree-bounded (i. e., the degrees of all monomials occuring with nonzero coefficient in p are bounded from above, although the bound can depend on p) and satisfy the following condition: For every tuple $(a_1, a_2, \ldots, a_m)$ of positive integers, the coefficient of the monomial $x_{i_1}^{a_1} x_{i_2}^{a_2} \cdots x_{i_m}^{a_m}$ in p is the same for all strictly increasing sequences $(i_1 < i_2 < \cdots < i_m)$ of positive integers. (In other words, the coefficient of a monomial in p depends only on the sequence of nonzero exponents in the monomial. If "sequence" were to be replaced by "multiset" here, we would obtain the definition of a symmetric function.)

The R-algebra of quasi-symmetric functions is commonly called QSym_R or occasionally just QSym (when R is clear from the context or $\mathbf{Z}$ or $\mathbf{Q}$). It is graded by the total degree of the power series. Its homogeneous elements of degree k form a free R-submodule of rank equal to the number of compositions of k (that is, 2^{k-1} if $k \geq 1$, else 1).

The two classical bases of QSym, the monomial basis $(M_I)_I$ and the fundamental basis $(F_I)_I$, are indexed by compositions $I = (I_1, I_2, \cdots, I_\ell)$ and defined by the formulas:

$$M_I = \sum_{1 \leq i_1 < i_2 < \cdots < i_\ell} x_{i_1}^{I_1} x_{i_2}^{I_2} \cdots x_{i_\ell}^{I_\ell}$$

and

$$F_I = \sum_{(j_1, j_2, \ldots, j_n)} x_{j_1} x_{j_2} \cdots x_{j_n}$$

where in the second equation the sum runs over all weakly increasing n-tuples $(j_1, j_2, \ldots, j_n)$ of positive integers (where n is the size of I) which increase strictly from j_r to j_{r+1} if r is a descent of the composition I.

These bases are related by the formula

$F_I = \sum_{J \leq I} M_J$

where the inequality $J \leq I$ indicates that J is finer than I.

The R-algebra of quasi-symmetric functions is a Hopf algebra, with the coproduct satisfying

$$\Delta M_I = \sum_{k=0}^{\ell} M_{(I_1,I_2,\cdots,I_k)} \otimes M_{(I_{k+1},I_{k+2},\cdots,I_\ell)}$$

for every composition $I = (I_1, I_2, \cdots, I_\ell)$.

It is possible to define an R-algebra of quasi-symmetric functions in a finite number of variables as well (but it is not a bialgebra). These quasi-symmetric functions are actual polynomials then, not just power series.

Chapter 5 of [GriRei2014] and Section 11 of [HazWitt1] are devoted to quasi-symmetric functions, as are Malvenuto's thesis [Mal1993] and part of Chapter 7 of [Sta-EC2].

The implementation of the quasi-symmetric function Hopf algebra

We realize the R-algebra of quasi-symmetric functions in Sage as a graded Hopf algebra with basis elements indexed by compositions:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.category()
Join of Category of hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
    and Category of coalgebras over Rational Field with realizations
```

The most standard two bases for this R-algebra are the monomial and fundamental bases, and are accessible by the `M()` and `F()` methods:

```
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,1,2])
M[1, 1, 1, 1, 1] + M[1, 1, 1, 2] + M[2, 1, 1, 1] + M[2, 1, 2]
sage: F(M[2,1,2])
F[1, 1, 1, 1, 1] - F[1, 1, 1, 2] - F[2, 1, 1, 1] + F[2, 1, 2]
```

The product on this space is commutative and is inherited from the product on the realization within the ring of power series:

```
sage: M[3]*M[1,1] == M[1,1]*M[3]
True
sage: M[3]*M[1,1]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[3, 1, 1] + M[4, 1]
sage: F[3]*F[1,1]
F[1, 1, 3] + F[1, 2, 2] + F[1, 3, 1] + F[1, 4] + F[2, 1, 2]
 + F[2, 2, 1] + F[2, 3] + F[3, 1, 1] + F[3, 2] + F[4, 1]
sage: M[3]*F[2]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[2, 3] + M[3, 1, 1] + M[3, 2]
 + M[4, 1] + M[5]
sage: F[2]*M[3]
F[1, 1, 1, 2] - F[1, 2, 2] + F[2, 1, 1, 1] - F[2, 1, 2] - F[2, 2, 1]
 + F[5]
```

There is a coproduct on QSym as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The coproduct is not co-commutative:

```
sage: M[1,3,1].coproduct()
M[] # M[1, 3, 1] + M[1] # M[3, 1] + M[1, 3] # M[1] + M[1, 3, 1] # M[]
```

```
sage: F[1,3,1].coproduct()
F[] # F[1, 3, 1] + F[1] # F[3, 1] + F[1, 1] # F[2, 1]
 + F[1, 2] # F[1, 1] + F[1, 3] # F[1] + F[1, 3, 1] # F[]
```

The duality pairing with non-commutative symmetric functions

These two operations endow the quasi-symmetric functions QSym with the structure of a Hopf algebra. It is the graded dual Hopf algebra of the non-commutative symmetric functions $NCSF$. Under this duality, the Monomial basis of QSym is dual to the Complete basis of $NCSF$, and the Fundamental basis of QSym is dual to the Ribbon basis of $NCSF$ (see [MR]).

```
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1
sage: M.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: F.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[1 1 0 0 0 0 0 0]
[1 0 1 0 0 0 0 0]
[1 1 1 1 0 0 0 0]
[1 0 0 0 1 0 0 0]
[1 1 0 0 1 1 0 0]
[1 0 1 0 1 0 1 0]
[1 1 1 1 1 1 1 1]
sage: NCSF = M.realization_of().dual()
sage: R = NCSF.Ribbon()
sage: F.duality_pairing_matrix( R, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: M.duality_pairing_matrix( R, degree=4 )
[ 1  0  0  0  0  0  0  0]
[-1  1  0  0  0  0  0  0]
[-1  0  1  0  0  0  0  0]
[ 1 -1 -1  1  0  0  0  0]
[-1  0  0  0  1  0  0  0]
[ 1 -1  0  0 -1  1  0  0]
[ 1  0 -1  0 -1  0  1  0]
[-1  1  1 -1  1 -1 -1  1]
```

Let H and G be elements of QSym, and h an element of $NCSF$. Then, if we represent the duality pairing with the mathematical notation $[\cdot, \cdot]$,

$[HG, h] = [H \otimes G, \Delta(h)]$.

For example, the coefficient of `M[2,1,4,1]` in `M[1,3]*M[2,1,1]` may be computed with the duality pairing:

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
1
```

And the coefficient of `S[1,3] # S[2,1,1]` in `S[2,1,4,1].coproduct()` is equal to this result:

```
sage: S[2,1,4,1].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if H is an element of QSym and g and h are elements of $NCSF$, then

$$[H, gh] = [\Delta(H), g \otimes h].$$

For example, the coefficient of `R[2,3,1]` in `R[2,1]*R[2,1]` is computed with the duality pairing by the following command:

```
sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])
1
sage: R[2,1]*R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```

This coefficient should then be equal to the coefficient of `F[2,1] # F[2,1]` in `F[2,3,1].coproduct()`:

```
sage: F[2,3,1].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1]  + ... + F[2, 3, 1] # F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

The operation dual to multiplication by a non-commutative symmetric function

Let $g \in NCSF$ and consider the linear endomorphism of $NCSF$ defined by left (respectively, right) multiplication by g. Since there is a duality between QSym and $NCSF$, this linear transformation induces an operator $g^{\perp}$ on QSym satisfying

$$[g^{\perp}(H), h] = [H, gh].$$

for any non-commutative symmetric function h.

This is implemented by the method `skew_by()`. Explicitly, if `H` is a quasi-symmetric function and `g` a non-commutative symmetric function, then `H.skew_by(g)` and `H.skew_by(g, side='right')` are expressions that satisfy, for any non-commutative symmetric function `h`, the following equalities:

```
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)
```

For example, `M[J].skew_by(S[I])` is 0 unless the composition `J` begins with `I` and `M(J).skew_by(S(I), side='right')` is 0 unless the composition `J` ends with `I`. For example:

```
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism( lambda x,y: x.duality_pairing(S[3])*y )
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

The counit

The counit is defined by sending all elements of positive degree to zero:

```
sage: M[3].degree(), M[3,1,2].degree(), M.one().degree()
(3, 6, 0)
sage: M[3].counit()
0
sage: M[3,1,2].counit()
0
sage: M.one().counit()
1
sage: (M[3] - 2*M[3,1,2] + 7).counit()
7
sage: (F[3] - 2*F[3,1,2] + 7).counit()
7
```

The antipode

The antipode sends the Fundamental basis element indexed by the composition I to $(-1)^{|I|}$ times the Fundamental basis element indexed by the conjugate composition to I (where $|I|$ stands for the size of I, that is, the sum of all entries of I).

```
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
```

The antipodes of the Monomial quasisymmetric functions can also be computed easily: Every composition I satisfies

$$\omega(M_I) = (-1)^{\ell(I)} \sum M_J,$$

where the sum ranges over all compositions J of $|I|$ which are coarser than the reversed composition I^r of I. Here, $\ell(I)$ denotes the length of the composition I (that is, the number of its parts).

```
sage: M[3,2,1].antipode()
-M[1, 2, 3] - M[1, 5] - M[3, 3] - M[6]
sage: M[3,2,2].antipode()
-M[2, 2, 3] - M[2, 5] - M[4, 3] - M[7]
```

We demonstrate here the defining relation of the antipode:

```
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

The relation with symmetric functions

The quasi-symmetric functions are a ring which contain the symmetric functions as a subring. The Monomial quasi-symmetric functions are related to the monomial symmetric functions by

$$m_\lambda = \sum_{\mathrm{sort}(I)=\lambda} M_I$$

(where $\mathrm{sort}(I)$ denotes the result of sorting the entries of I in decreasing order).

There are methods to test if an expression in the quasi-symmetric functions is a symmetric function and, if it is, send it to an expression in the symmetric functions:

```
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: g = M[3,1] + M[1,3]
sage: g.is_symmetric()
True
sage: g.to_symmetric_function()
m[3, 1]
```

The expansion of the Schur function in terms of the Fundamental quasi-symmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```
sage: f = F[3,2] + F[2,2,1] + F[2,3] + F[1,3,1] + F[1,2,2]
sage: f.is_symmetric()
True
sage: f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: s(f.to_symmetric_function())
s[3, 2]
```

It is also possible to convert a symmetric function to a quasi-symmetric function:

```
sage: m = SymmetricFunctions(QQ).m()
sage: M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: F( s[2,2,1] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]
```

It is possible to experiment with the quasi-symmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

```
sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSymt = QuasiSymmetricFunctions(R)
sage: Ft = QSymt.F()
sage: Ft( Qp[2,2] )
F[1, 2, 1] + t*F[1, 3] + (t+1)*F[2, 2] + t*F[3, 1] + t^2*F[4]

sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of `F` is not equal to the base ring of `Ht`:

```
sage: F(Ht[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self (=Quasisymmetric functic
```

The map to the ring of polynomials

The quasi-symmetric functions can be seen as an inverse limit of a subring of a polynomial ring as the number of variables increases. Indeed, there exists a projection from the quasi-symmetric functions onto the polynomial ring $R[x_1, x_2, \ldots, x_n]$. This projection is defined by sending the variables $x_{n+1}, x_{n+2}, \cdots$ to 0, while the remaining n variables remain fixed. Note that this projection sends M_I to 0 if the length of the composition I is higher than n.

```
sage: M[1,3,1].expand(4)
x0*x1^3*x2 + x0*x1^3*x3 + x0*x2^3*x3 + x1*x2^3*x3
sage: F[1,3,1].expand(4)
x0*x1^3*x2 + x0*x1^3*x3 + x0*x1^2*x2*x3 + x0*x1*x2^2*x3 + x0*x2^3*x3 + x1*x2^3*x3
sage: M[1,3,1].expand(2)
0
```

TESTS:

```
sage: QSym = QuasiSymmetricFunctions(QQ); QSym
Quasisymmetric functions over the Rational Field
sage: QSym.base_ring()
Rational Field
```

class Bases (*parent_with_realization*)

Bases: `sage.categories.realizations.Category_realization_of_parent`

Category of bases of quasi-symmetric functions.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.Bases()
Category of bases of Quasisymmetric functions over the Rational Field
```

class ElementMethods

Methods common to all elements of `QuasiSymmetricFunctions`.

adams_operation(**args*, ***opts*)

dendriform_leq(*other*)

Return the result of applying the dendriform smaller-or-equal operation to the two quasi-symmetric functions `self` and `other`.

The dendriform smaller-or-equal operation is a binary operation, denoted by $\preceq$ and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by $\preceq$ and written infix as well) on the ring of formal power series $R[[x_1, x_2, x_3, \ldots]]$, which is defined as follows: If m and n are two monomials in $x_1, x_2, x_3, \ldots$, then we let $m \preceq n$ be the product mn if the smallest positive integer i for which x_i occurs in m is smaller or equal to the smallest positive integer j for which x_j occurs in n (this is understood to be false when $m = 1$ and $n \neq 1$, and true when $n = 1$), and we let $m \preceq n$ be 0 otherwise. Having thus defined $\preceq$ on monomials, we extend $\preceq$ to a binary operation on $R[[x_1, x_2, x_3, \ldots]]$ by requiring it to be continuous (in both inputs) and R-bilinear. It is easily seen that $QSym \preceq QSym \subseteq QSym$, so that $\preceq$ restricts to a binary operation on $QSym$.

This operation $\preceq$ is related to the dendriform smaller relation $\prec$ (`dendriform_less()`). Namely, if we define a binary operation $\succ$ on $QSym$ by $a \succ b = b \prec a$, then $(QSym, \preceq, \succ)$ is a dendriform R-algebra. Thus, any $a, b \in QSym$ satisfy $a \preceq b = ab - b \prec a$.

See also:

`dendriform_less()`

INPUT:

- `other` – a quasi-symmetric function over the same base ring as `self`

OUTPUT:

The quasi-symmetric function `self` $\preceq$ `other`, written in the basis of `self`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_leq(M[1, 2])
2*M[2, 1, 1, 2] + M[2, 1, 2, 1] + M[2, 1, 3] + M[2, 2, 2]
 + M[3, 1, 2] + M[3, 2, 1] + M[3, 3]
sage: F = QSym.F()
sage: F[2, 1].dendriform_leq(F[1, 2])
F[2, 1, 1, 2] + F[2, 1, 2, 1] + F[2, 1, 3] + F[2, 2, 1, 1]
 + 2*F[2, 2, 2] + F[2, 3, 1] + F[3, 1, 2] + F[3, 2, 1] + F[3, 3]
```

dendriform_less(*other*)

Return the result of applying the dendriform smaller operation to the two quasi-symmetric functions `self` and `other`.

The dendriform smaller operation is a binary operation, denoted by $\prec$ and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by $\prec$ and written infix as well) on the ring of formal power series $R[[x_1, x_2, x_3, \ldots]]$, which is defined as follows: If m and n are two monomials in $x_1, x_2, x_3, \ldots$, then we let $m \prec n$ be the product mn if the smallest positive integer i for which x_i occurs in m is smaller than the smallest positive integer j for which x_j occurs in n (this is understood to be false when $m = 1$, and true when $m \neq 1$ and $n = 1$), and we let $m \prec n$ be 0 otherwise. Having thus defined $\prec$ on monomials, we extend $\prec$ to a binary operation on $R[[x_1, x_2, x_3, \ldots]]$ by requiring it to be continuous (in both inputs) and R-bilinear. It is easily seen that $QSym \prec QSym \subseteq QSym$, so that $\prec$ restricts to a binary operation on $QSym$.

See also:

`dendriform_leq()`

INPUT:

•other – a quasi-symmetric function over the same base ring as self

OUTPUT:

The quasi-symmetric function self $\prec$ other, written in the basis of self.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_less(M[1, 2])
2*M[2, 1, 1, 2] + M[2, 1, 2, 1] + M[2, 1, 3] + M[2, 2, 2]
sage: F = QSym.F()
sage: F[2, 1].dendriform_less(F[1, 2])
F[1, 1, 2, 1, 1] + F[1, 1, 2, 2] + F[1, 1, 3, 1]
 + F[1, 2, 1, 2] + F[1, 2, 2, 1] + F[1, 2, 3]
 + F[2, 1, 1, 2] + F[2, 1, 2, 1] + F[2, 1, 3] + F[2, 2, 2]
```

The operation $\prec$ can be used to recursively construct the dual immaculate basis: For every positive integer m and every composition I, the dual immaculate function $\mathrm{dI}_{[m,I]}$ of the composition $[m, I]$ (this composition is I with m prepended to it) is $F_{[m]} \prec \mathrm{dI}_I$.

```
sage: dI = QSym.dI()
sage: dI(F[2]).dendriform_less(dI[1, 2])
dI[2, 1, 2]
```

We check with the identity element:

```
sage: M.one().dendriform_less(M[1,2])
0
sage: M[1,2].dendriform_less(M.one())
M[1, 2]
```

The operation $\prec$ is not symmetric, nor if $a \prec b \neq 0$, then $b \prec a = 0$ (as it would be for a single monomial):

```
sage: M[1,2,1].dendriform_less(M[1,2])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3]
 + M[1, 1, 4, 1] + 2*M[1, 2, 1, 1, 2] + M[1, 2, 1, 2, 1]
 + M[1, 2, 1, 3] + M[1, 2, 2, 2] + M[1, 3, 1, 2]
 + M[1, 3, 2, 1] + M[1, 3, 3]
sage: M[1,2].dendriform_less(M[1,2,1])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3]
 + M[1, 1, 4, 1] + M[1, 2, 1, 2, 1] + M[1, 3, 2, 1]
```

expand(*n*, *alphabet='x'*)

Expand the quasi-symmetric function into n variables in an alphabet, which by default is 'x'.

INPUT:

•n – A nonnegative integer; the number of variables in the expansion

•alphabet – (default: 'x'); the alphabet in which self is to be expanded

OUTPUT:

•An expansion of self into the n variables specified by alphabet.

EXAMPLES:

```
sage: F=QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(3)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 +
sage: F[2,1].expand(3)
x0^2*x1 + x0^2*x2 + x0*x1*x2 + x1^2*x2
```

One can use a different set of variable by adding an optional argument alphabet=...

```
sage: F=QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(2,alphabet='y')
```

```
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
```

TESTS:

```
sage: (3*F([])).expand(2)
3
sage: F[4,2].expand(0)
0
sage: F([]).expand(0)
1
```

frobenius(*n*)

Return the image of the quasi-symmetric function `self` under the n-th Frobenius operator.

The n-th Frobenius operator $\mathbf{f}_n$ is defined to be the map from the R-algebra of quasi-symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$f_n M_{(i_1,i_2,i_3,\ldots)} = M_{(ni_1,ni_2,ni_3,\ldots)}$$

for every composition $(i_1, i_2, i_3, \ldots)$ (where M means the monomial basis).

The n-th Frobenius operator is also called the n-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n-th Frobenius operator is also the n-th Adams operator of the Λ-ring of quasi-symmetric functions over the integers.

The restriction of the n-th Frobenius operator to the subring formed by all symmetric functions is, not unexpectedly, the n-th Frobenius operator of the ring of symmetric functions.

See also:

`Symmetric functions plethsym`

INPUT:

- n – a positive integer

OUTPUT:

The result of applying the n-th Frobenius operator (on the ring of quasi-symmetric functions) to `self`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M[3,2].frobenius(2)
M[6, 4]
sage: (M[2,1] - 2*M[3]).frobenius(4)
M[8, 4] - 2*M[12]
sage: M([]).frobenius(3)
M[]
sage: F[1,1].frobenius(2)
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
```

The Frobenius endomorphisms are multiplicative:

```
sage: all( all( M(I).frobenius(3) * M(J).frobenius(3)
....:           == (M(I) * M(J)).frobenius(3)
....:           for I in Compositions(3) )
....:      for J in Compositions(2) )
True
```

Being Hopf algebra endomorphisms, the Frobenius operators commute with the antipode:

```
sage: all( M(I).frobenius(4).antipode()
....:      == M(I).antipode().frobenius(4)
....:      for I in Compositions(3) )
True
```

The restriction of the Frobenius operators to the subring of symmetric functions are the Frobenius operators of the latter:

```
sage: e = SymmetricFunctions(ZZ).e()
sage: all( M(e(lam)).frobenius(3)
....:      == M(e(lam).frobenius(3))
....:      for lam in Partitions(3) )
True
```

internal_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism $\Delta^{\times}$ from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If I is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is I. If A is a $(0, I)$-matrix, then $\mathrm{row}(A)$ will denote the vector of row sums of A (regarded as a composition), and $\mathrm{column}(A)$ will denote the vector of column sums of A (regarded as a composition).

   For every composition I, the internal coproduct $\Delta^{\times}(M_I)$ of the I-th monomial quasisymmetric function M_I is the sum

   $$\sum_{A \text{ is a } (0,I)\text{-matrix}} M_{\mathrm{row}(A)} \otimes M_{\mathrm{column}(A)}.$$

   See Section 11.39 of [HazWitt1].

2. For every permutation w, let $C(w)$ denote the descent composition of w. Then, for any composition I of size n, the internal coproduct $\Delta^{\times}(F_I)$ of the I-th fundamental quasisymmetric function F_I is the sum

   $$\sum_{\substack{\sigma \in S_n, \\ \tau \in S_n, \\ \tau\sigma = \pi}} F_{C(\sigma)} \otimes F_{C(\tau)},$$

   where π is any permutation in S_n having descent composition I and where permutations act from the left and multiply accordingly, so $\tau\sigma$ means first applying σ and then τ. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the R-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method `kronecker_coproduct()` is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of M_{21} (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$\begin{bmatrix} 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^{\times}(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

Further examples:

```
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
....:      for i in range(1, 4) )
True

sage: M([1, 2]).internal_coproduct()
M[1, 2] # M[1, 2] + M[1, 2] # M[2, 1] + M[1, 2] # M[3] + M[3] # M[1, 2]
```

The definition of $\Delta^{\times}(M_I)$ in terms of $(0, I)$-matrices is not suitable for computation in cases where the length of I is large, but we can use it as a doctest. Here is a naive implementation:

```
sage: def naive_internal_coproduct_on_M(I):
....:     # INPUT: composition I
....:     #        (not quasi-symmetric function)
....:     # OUTPUT: interior coproduct of M_I
....:     M = QuasiSymmetricFunctions(ZZ).M()
....:     M2 = M.tensor(M)
....:     res = M2.zero()
....:     l = len(I)
....:     n = I.size()
....:     for S in Subsets(range(l**2), l):
....:         M_list = sorted(S)
....:         row_M = [sum([I[M_list.index(l * i + j)]
....:                       for j in range(l) if
....:                       l * i + j in S])
....:                  for i in range(l)]
....:         col_M = [sum([I[M_list.index(l * i + j)]
....:                       for i in range(l) if
....:                       l * i + j in S])
....:                  for j in range(l)]
....:         if 0 in row_M:
....:             first_zero = row_M.index(0)
....:             row_M = row_M[:first_zero]
....:             if sum(row_M) != n:
....:                 continue
....:         if 0 in col_M:
....:             first_zero = col_M.index(0)
....:             col_M = col_M[:first_zero]
....:             if sum(col_M) != n:
....:                 continue
....:         res += tensor([M(Compositions(n)(row_M)),
....:                        M(Compositions(n)(col_M))])
....:     return res
sage: all( naive_internal_coproduct_on_M(I)
....:      == M(I).internal_coproduct()
....:      for I in Compositions(3) )
True
```

TESTS:

Border cases:

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: M([]).internal_coproduct()
M[] # M[]
sage: F([]).internal_coproduct()
F[] # F[]
```

The implementations on the `F` and `M` bases agree with each other:

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: def int_copr_on_F_via_M(I):
....:     result = tensor([F.zero(), F.zero()])
....:     w = M(F(I)).internal_coproduct()
....:     for lam, a in w:
....:         (U, V) = lam
....:         result += a * tensor([F(M(U)), F(M(V))])
....:     return result
sage: all( int_copr_on_F_via_M(I) == F(I).internal_coproduct()
....:      for I in Compositions(3) )
True
sage: all( int_copr_on_F_via_M(I) == F(I).internal_coproduct()
....:      for I in Compositions(4) )
True
```

Restricting to the subring of symmetric functions gives the standard internal coproduct on the latter:

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_copr_of_e_in_M(mu):
....:     result = tensor([M.zero(), M.zero()])
....:     w = e(mu).internal_coproduct()
....:     for lam, a in w:
....:         (nu, kappa) = lam
....:         result += a * tensor([M(e(nu)), M(e(kappa))])
....:     return result
sage: all( int_copr_of_e_in_M(mu) == M(e(mu)).internal_coproduct()
....:      for mu in Partitions(3) )
True
sage: all( int_copr_of_e_in_M(mu) == M(e(mu)).internal_coproduct()
....:      for mu in Partitions(4) )
True
```

Todo

Implement this directly on the monomial basis maybe? The $(0, I)$-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above "further examples" should be moved to the M-method.

---

is_symmetric()

Return `True` if `self` is an element of the symmetric functions.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:

- `True` if `self` is symmetric. `False` if `self` is not symmetric.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).is_symmetric()
False
sage: (F[1, 1, 1, 2] + F[1, 1, 3] + F[1, 3, 1] + F[2, 1, 1, 1] + F[3, 1, 1]).is_symme
True
sage: F([]).is_symmetric()
True
```

kronecker_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism $\Delta^\times$ from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If I is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is I. If A is a $(0, I)$-matrix, then $\mathrm{row}(A)$ will denote the vector of row sums of A (regarded as a composition), and $\mathrm{column}(A)$ will denote the vector of column sums of A (regarded as a composition).

   For every composition I, the internal coproduct $\Delta^\times(M_I)$ of the I-th monomial quasisymmetric function M_I is the sum

   $$\sum_{A \text{ is a } (0,I)\text{-matrix}} M_{\mathrm{row}(A)} \otimes M_{\mathrm{column}(A)}.$$

   See Section 11.39 of [HazWitt1].

2. For every permutation w, let $C(w)$ denote the descent composition of w. Then, for any composition I of size n, the internal coproduct $\Delta^\times(F_I)$ of the I-th fundamental quasisymmetric function F_I is the sum

   $$\sum_{\substack{\sigma \in S_n, \\ \tau \in S_n, \\ \tau\sigma = \pi}} F_{C(\sigma)} \otimes F_{C(\tau)},$$

   where π is any permutation in S_n having descent composition I and where permutations act from the left and multiply accordingly, so $\tau\sigma$ means first applying σ and then τ. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the R-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method `kronecker_coproduct()` is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of M_{21} (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$\begin{bmatrix} 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

Further examples:

```
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
....:      for i in range(1, 4) )
True

sage: M([1, 2]).internal_coproduct()
M[1, 2] # M[1, 2] + M[1, 2] # M[2, 1] + M[1, 2] # M[3] + M[3] # M[1, 2]
```

The definition of $\Delta^{\times}(M_I)$ in terms of $(0, I)$-matrices is not suitable for computation in cases where the length of I is large, but we can use it as a doctest. Here is a naive implementation:

```
sage: def naive_internal_coproduct_on_M(I):
....:     # INPUT: composition I
....:     #        (not quasi-symmetric function)
....:     # OUTPUT: interior coproduct of M_I
....:     M = QuasiSymmetricFunctions(ZZ).M()
....:     M2 = M.tensor(M)
....:     res = M2.zero()
....:     l = len(I)
....:     n = I.size()
....:     for S in Subsets(range(l**2), l):
....:         M_list = sorted(S)
....:         row_M = [sum([I[M_list.index(l * i + j)]
....:                       for j in range(l) if
....:                       l * i + j in S])
....:                  for i in range(l)]
....:         col_M = [sum([I[M_list.index(l * i + j)]
....:                       for i in range(l) if
....:                       l * i + j in S])
....:                  for j in range(l)]
....:         if 0 in row_M:
....:             first_zero = row_M.index(0)
....:             row_M = row_M[:first_zero]
....:             if sum(row_M) != n:
....:                 continue
....:         if 0 in col_M:
....:             first_zero = col_M.index(0)
....:             col_M = col_M[:first_zero]
....:             if sum(col_M) != n:
....:                 continue
....:         res += tensor([M(Compositions(n)(row_M)),
....:                        M(Compositions(n)(col_M))])
....:     return res
sage: all( naive_internal_coproduct_on_M(I)
....:      == M(I).internal_coproduct()
....:      for I in Compositions(3) )
True
```

TESTS:

Border cases:

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: M([]).internal_coproduct()
```

```
M[] # M[]
sage: F([]).internal_coproduct()
F[] # F[]
```

The implementations on the `F` and `M` bases agree with each other:

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: def int_copr_on_F_via_M(I):
....:     result = tensor([F.zero(), F.zero()])
....:     w = M(F(I)).internal_coproduct()
....:     for lam, a in w:
....:         (U, V) = lam
....:         result += a * tensor([F(M(U)), F(M(V))])
....:     return result
sage: all( int_copr_on_F_via_M(I) == F(I).internal_coproduct()
....:      for I in Compositions(3) )
True
sage: all( int_copr_on_F_via_M(I) == F(I).internal_coproduct()
....:      for I in Compositions(4) )
True
```

Restricting to the subring of symmetric functions gives the standard internal coproduct on the latter:

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_copr_of_e_in_M(mu):
....:     result = tensor([M.zero(), M.zero()])
....:     w = e(mu).internal_coproduct()
....:     for lam, a in w:
....:         (nu, kappa) = lam
....:         result += a * tensor([M(e(nu)), M(e(kappa))])
....:     return result
sage: all( int_copr_of_e_in_M(mu) == M(e(mu)).internal_coproduct()
....:      for mu in Partitions(3) )
True
sage: all( int_copr_of_e_in_M(mu) == M(e(mu)).internal_coproduct()
....:      for mu in Partitions(4) )
True
```

Todo

Implement this directly on the monomial basis maybe? The $(0, I)$-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above "further examples" should be moved to the M-method.

---

omega_involution()

Return the image of the quasisymmetric function `self` under the omega involution.

The omega involution is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the fundamental quasisymmetric function F_I to F_{I^t}, where I^t denotes the conjugate (`conjugate()`) of the composition I. This map is commonly denoted by ω. It is an algebra homomorphism and a coalgebra antihomomorphism; it also is an involution and an automorphism of the graded vector space $QSym$. Also, every composition I satisfies

$$\omega(M_I) = (-1)^{|I|-\ell(I)} \sum M_J,$$

where the sum ranges over all compositions J of $|I|$ which are coarser than the reversed composition I^r of I. Here, $\ell(I)$ denotes the length of the composition I (that is, the number of parts of

I).

If f is a homogeneous element of $NCSF$ of degree n, then

$$\omega(f) = (-1)^n S(f),$$

where S denotes the antipode of $QSym$.

The restriction of ω to the ring of symmetric functions (which is a subring of $QSym$) is precisely the omega involution (`omega()`) of said ring.

The omega involution on $QSym$ is adjoint to the omega involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The omega involution has been denoted by ω in [LMvW13], section 3.6.

See also:

`omega involution on NCSF`, `psi involution on QSym`, `star involution on QSym`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].omega_involution()
F[1, 2, 1, 1]
sage: F[6,3].omega_involution()
F[1, 1, 2, 1, 1, 1, 1, 1]
sage: (F[9,1] - F[8,2] + 2*F[2,4] - 3*F[3] + 4*F[[]]).omega_involution()
4*F[] - 3*F[1, 1, 1] + 2*F[1, 1, 1, 2, 1] - F[1, 2, 1, 1, 1, 1, 1, 1, 1] + F[2, 1, 1,
sage: (F[3,3] - 2*F[2]).omega_involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: F([2,1,1]).omega_involution()
F[3, 1]
sage: M = QSym.M()
sage: M([2,1]).omega_involution()
-M[1, 2] - M[3]
sage: M.zero().omega_involution()
0
```

Testing the fact that the restriction of ω to Sym is the omega automorphism of Sym:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).omega_involution() == F(e[lam].omega())
....:      for lam in Partitions(4) )
True
```

psi_involution()

Return the image of the quasisymmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the fundamental quasisymmetric function F_I to F_{I^c}, where I^c denotes the complement of the composition I. The map ψ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution ψ of $QSym$ is adjoint to the involution ψ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also:

psi involution on NCSF, star involution on QSym.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].psi_involution()
F[1, 1, 2, 1]
sage: F[6,3].psi_involution()
F[1, 1, 1, 1, 1, 2, 1, 1]
sage: (F[9,1] - F[8,2] + 2*F[2,4] - 3*F[3] + 4*F[[]]).psi_involution()
4*F[] - 3*F[1, 1, 1] + F[1, 1, 1, 1, 1, 1, 1, 1, 2] - F[1, 1, 1, 1, 1, 1, 1, 2, 1] +
sage: (F[3,3] - 2*F[2]).psi_involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: F([2,1,1]).psi_involution()
F[1, 3]
sage: M = QSym.M()
sage: M([2,1]).psi_involution()
-M[2, 1] - M[3]
sage: M.zero().psi_involution()
0
```

The involution ψ commutes with the antipode:

```
sage: all( F(I).psi_involution().antipode()
....:      == F(I).antipode().psi_involution()
....:      for I in Compositions(4) )
True
```

Testing the fact that the restriction of ψ to Sym is the omega automorphism of Sym:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).psi_involution() == F(e[lam].omega())
....:      for lam in Partitions(4) )
True
```

star_involution()

Return the image of the quasisymmetric function `self` under the star involution.

The star involution is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the monomial quasisymmetric function M_I to M_{I^r}. Here, if I is a composition, we denote by I^r the reversed composition of I. Denoting by f^* the image of an element $f \in QSym$ under the star involution, it can be shown that every composition I satisfies

$$(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},$$

where F_I denotes the fundamental quasisymmetric function corresponding to the composition I. The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $QSym$. It also is an automorphism of the graded vector space $QSym$, and is the identity on the subspace Sym of $QSym$. It is adjoint to the star involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6.

See also:

star involution on NCSF.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].star_involution()
```

```
M[2, 3]
sage: M[6,3].star_involution()
M[3, 6]
sage: (M[9,1] - M[6,2] + 2*M[6,4] - 3*M[3] + 4*M[[]]).star_involution()
4*M[] + M[1, 9] - M[2, 6] - 3*M[3] + 2*M[4, 6]
sage: (M[3,3] - 2*M[2]).star_involution()
-2*M[2] + M[3, 3]
sage: M([4,2]).star_involution()
M[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

The star involution commutes with the antipode:

```
sage: all( M(I).star_involution().antipode()
....:      == M(I).antipode().star_involution()
....:      for I in Compositions(4) )
True
```

The star involution is the identity on Sym:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( M(e(lam)).star_involution() == M(e(lam))
....:      for lam in Partitions(4) )
True
```

to_symmetric_function()

Convert a quasi-symmetric function to a symmetric function.

OUTPUT:

- If `self` is a symmetric function, then return the expansion in the monomial basis. Otherwise raise an error.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
sage: m = SymmetricFunctions(QQ).m()
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,1,1]).to_symmetric_function()
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
sage: m(s[3,1,1])
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
```

class QuasiSymmetricFunctions.Bases.**ParentMethods**

Methods common to all bases of `QuasiSymmetricFunctions`.

Eulerian(*n*, *j*, *k=None*)

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ in terms of `self`.

INPUT:

- `n` – the value n or a partition
- `j` – the number of excedances
- `k` – (optional) if specified, determines the number of fixed points of the permtutation

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M.Eulerian(3, 1)
4*M[1, 1, 1] + 3*M[1, 2] + 3*M[2, 1] + 2*M[3]
sage: M.Eulerian(4, 1, 2)
6*M[1, 1, 1, 1] + 4*M[1, 1, 2] + 4*M[1, 2, 1]
 + 2*M[1, 3] + 4*M[2, 1, 1] + 3*M[2, 2] + 2*M[3, 1] + M[4]
sage: QS = QSym.QS()
sage: QS.Eulerian(4, 2)
2*QS[1, 3] + QS[2, 2] + 2*QS[3, 1] + 3*QS[4]
sage: QS.Eulerian([2, 2, 1], 2)
QS[1, 2, 2] + QS[1, 4] + QS[2, 1, 2] + QS[2, 2, 1]
 + QS[2, 3] + QS[3, 2] + QS[4, 1] + QS[5]
sage: dI = QSym.dI()
sage: dI.Eulerian(5, 2)
-dI[1, 3, 1] - 5*dI[1, 4] + dI[2, 2, 1] + dI[3, 1, 1]
 + 5*dI[3, 2] + 6*dI[4, 1] + 6*dI[5]
```

from_polynomial (*f*, *check=True*)

The quasi-symmetric function expanded in this basis corresponding to the quasi-symmetric polynomial `f`.

This is a default implementation that computes the expansion in the Monomial basis and converts to this basis.

INPUT:

- `f` – a polynomial in finitely many variables over the same base ring as `self`. It is assumed that this polynomial is quasi-symmetric.
- `check` – boolean (default: `True`), checks whether the polynomial is indeed quasi-symmetric.

OUTPUT:

- quasi-symmetric function

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: M.from_polynomial(f)
M[1]
sage: F.from_polynomial(f)
F[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: M.from_polynomial(f)
M[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

If the polynomial is not quasi-symmetric, an error is raised:

```
sage: f = x[0]^2+x[1]
sage: M.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
sage: F.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
```

TESTS:

We convert some quasi-symmetric functions to quasi-symmetric polynomials and back:

```
sage: f = (M[1,2] + M[1,1]).expand(3); f
x0*x1^2 + x0*x2^2 + x1*x2^2 + x0*x1 + x0*x2 + x1*x2
sage: M.from_polynomial(f)
M[1, 1] + M[1, 2]
sage: f = (2*M[2,1]+M[1,1]+3*M[3]).expand(3)
sage: M.from_polynomial(f)
M[1, 1] + 2*M[2, 1] + 3*M[3]
sage: f = (F[1,2] + F[1,1]).expand(3); f
x0*x1^2 + x0*x1*x2 + x0*x2^2 + x1*x2^2 + x0*x1 + x0*x2 + x1*x2
sage: F.from_polynomial(f)
F[1, 1] + F[1, 2]
sage: f = (2*F[2,1]+F[1,1]+3*F[3]).expand(3)
sage: F.from_polynomial(f)
F[1, 1] + 2*F[2, 1] + 3*F[3]
```

QuasiSymmetricFunctions.Bases.**super_categories**()

Return the super categories of bases of the Quasi-symmetric functions.

OUTPUT:

- a list of categories

TESTS:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.Bases().super_categories()
[Category of commutative bases of Non-Commutative Symmetric Functions or Quasisymmetric
```

class QuasiSymmetricFunctions.**Fundamental**(*QSym*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of quasi-symmetric functions in the Fundamental basis.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(M[2,2])
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,2])
F[1, 2, 2] + F[1, 3, 1] + F[2, 2, 1] + F[2, 3] + F[3, 2]
sage: (1+F[1])^3
F[] + 3*F[1] + 3*F[1, 1] + F[1, 1, 1] + 2*F[1, 2] + 3*F[2] + 2*F[2, 1] + F[3]
sage: F[1,2,1].coproduct()
F[] # F[1, 2, 1] + F[1] # F[2, 1] + F[1, 1] # F[1, 1] + F[1, 2] # F[1] + F[1, 2, 1] # F[]
```

The following is an alias for this basis:

```
sage: QSym.Fundamental()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

TESTS:

```
sage: F(M([]))
F[]
sage: F(M(0))
0
sage: F(s([]))
```

```
F[]
sage: F(s(0))
0
```

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

internal_coproduct()

Return the inner coproduct of self in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism $\Delta^{\times}$ from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If I is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is I. If A is a $(0, I)$-matrix, then $\mathrm{row}(A)$ will denote the vector of row sums of A (regarded as a composition), and $\mathrm{column}(A)$ will denote the vector of column sums of A (regarded as a composition).

   For every composition I, the internal coproduct $\Delta^{\times}(M_I)$ of the I-th monomial quasisymmetric function M_I is the sum

   $$\sum_{A \text{ is a } (0,I)\text{-matrix}} M_{\mathrm{row}(A)} \otimes M_{\mathrm{column}(A)}.$$

   See Section 11.39 of [HazWitt1].

2. For every permutation w, let $C(w)$ denote the descent composition of w. Then, for any composition I of size n, the internal coproduct $\Delta^{\times}(F_I)$ of the I-th fundamental quasisymmetric function F_I is the sum

   $$\sum_{\substack{\sigma \in S_n, \\ \tau \in S_n, \\ \tau\sigma = \pi}} F_{C(\sigma)} \otimes F_{C(\tau)},$$

   where π is any permutation in S_n having descent composition I and where permutations act from the left and multiply accordingly, so $\tau\sigma$ means first applying σ and then τ. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the R-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method kronecker_coproduct() is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of M_{21} (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$\begin{bmatrix} 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^{\times}(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

Some examples on the Fundamental basis:

```
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
F[1, 1] # F[2] + F[2] # F[1, 1]
sage: F([2]).internal_coproduct()
F[1, 1] # F[1, 1] + F[2] # F[2]
sage: F([3]).internal_coproduct()
F[1, 1, 1] # F[1, 1, 1] + F[1, 2] # F[1, 2] + F[1, 2] # F[2, 1]
 + F[2, 1] # F[1, 2] + F[2, 1] # F[2, 1] + F[3] # F[3]
sage: F([1,2]).internal_coproduct()
F[1, 1, 1] # F[1, 2] + F[1, 2] # F[2, 1] + F[1, 2] # F[3]
 + F[2, 1] # F[1, 1, 1] + F[2, 1] # F[2, 1] + F[3] # F[1, 2]
```

kronecker_coproduct()

Return the inner coproduct of `self` in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism $\Delta^{\times}$ from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If I is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is I. If A is a $(0, I)$-matrix, then $\mathrm{row}(A)$ will denote the vector of row sums of A (regarded as a composition), and $\mathrm{column}(A)$ will denote the vector of column sums of A (regarded as a composition).

   For every composition I, the internal coproduct $\Delta^{\times}(M_I)$ of the I-th monomial quasisymmetric function M_I is the sum

   $$\sum_{A \text{ is a } (0,I)\text{-matrix}} M_{\mathrm{row}(A)} \otimes M_{\mathrm{column}(A)}.$$

   See Section 11.39 of [HazWitt1].

2. For every permutation w, let $C(w)$ denote the descent composition of w. Then, for any composition I of size n, the internal coproduct $\Delta^{\times}(F_I)$ of the I-th fundamental quasisymmetric function F_I is the sum

   $$\sum_{\substack{\sigma \in S_n, \\ \tau \in S_n, \\ \tau\sigma = \pi}} F_{C(\sigma)} \otimes F_{C(\tau)},$$

where π is any permutation in S_n having descent composition I and where permutations act from the left and multiply accordingly, so $\tau\sigma$ means first applying σ and then τ. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the R-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method `kronecker_coproduct()` is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of M_{21} (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$\begin{bmatrix} 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^{\times}(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

Some examples on the Fundamental basis:

```
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
F[1, 1] # F[2] + F[2] # F[1, 1]
sage: F([2]).internal_coproduct()
F[1, 1] # F[1, 1] + F[2] # F[2]
sage: F([3]).internal_coproduct()
F[1, 1, 1] # F[1, 1, 1] + F[1, 2] # F[1, 2] + F[1, 2] # F[2, 1]
 + F[2, 1] # F[1, 2] + F[2, 1] # F[2, 1] + F[3] # F[3]
sage: F([1,2]).internal_coproduct()
F[1, 1, 1] # F[1, 2] + F[1, 2] # F[2, 1] + F[1, 2] # F[3]
 + F[2, 1] # F[1, 1, 1] + F[2, 1] # F[2, 1] + F[3] # F[1, 2]
```

star_involution()

Return the image of the quasisymmetric function `self` under the star involution.

The star involution is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the monomial quasisymmetric function M_I to M_{I^r}. Here, if I is a composition, we denote by I^r the reversed composition of I. Denoting by f^* the image of an element $f \in QSym$ under the star involution, it can be shown that every composition I satisfies

$$(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},$$

where F_I denotes the fundamental quasisymmetric function corresponding to the composition I. The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $QSym$. It also is an automorphism of the graded vector space $QSym$, and is the identity on the subspace Sym of $QSym$. It is adjoint to the star involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6.

See also:

star involution on QSym, star involution on NCSF.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,1].star_involution()
F[1, 3]
sage: F[5,3].star_involution()
F[3, 5]
sage: (F[9,1] - F[6,2] + 2*F[6,4] - 3*F[3] + 4*F[[]]).star_involution()
4*F[] + F[1, 9] - F[2, 6] - 3*F[3] + 2*F[4, 6]
sage: (F[3,3] - 2*F[2]).star_involution()
-2*F[2] + F[3, 3]
sage: F([4,2]).star_involution()
F[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

QuasiSymmetricFunctions.Fundamental.**Eulerian**(*n*, *j*, *k=None*)

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ (with n either an integer or a partition) defined in [SW2010] in terms of the fundamental quasisymmetric functions. Or, if the optional argument k is specified, return the function $Q_{n,j,k}$ defined ibidem.

If n and j are nonnegative integers, then the Eulerian quasisymmetric function $Q_{n,j}$ is defined as

$$Q_{n,j} := \sum_{\sigma} F_{\mathrm{Dex}(\sigma)},$$

where we sum over all permutations $\sigma \in S_n$ such that the number of excedances of σ is j, and where $\mathrm{Dex}(\sigma)$ is a composition of n defined as follows: Let S be the set of all $i \in \{1, 2, \ldots, n-1\}$ such that either $\sigma_i > \sigma_{i+1} > i+1$ or $i \geq \sigma_i > \sigma_{i+1}$ or $\sigma_{i+1} > i+1 > \sigma_i$. Then, $\mathrm{Dex}(\sigma)$ is set to be the composition of n whose descent set is S.

Here, an excedance of a permutation $\sigma \in S_n$ means an element $i \in \{1, 2, \ldots, n-1\}$ satisfying $\sigma_i > i$.

Similarly we can define a quasisymmetric function $Q_{\lambda,j}$ for every partition λ and every nonnegative integer j. This differs from $Q_{n,j}$ only in that the sum is restricted to all permutations $\sigma \in S_n$ whose cycle type is λ (where $n = |\lambda|$, and where we still require the number of excedances to be j). The method at hand allows computing these functions by passing λ as the n parameter.

Analogously we can define a quasisymmetric function $Q_{n,j,k}$ for any nonnegative integers n, j and k by restricting the sum to all permutations $\sigma \in S_n$ that have exactly k fixed points (and j excedances). This can be obtained by specifying the optional k argument in this method.

All three versions of Eulerian quasisymmetric functions ($Q_{n,j}$, $Q_{\lambda,j}$ and $Q_{n,j,k}$) are actually symmetric functions. See Eulerian().

INPUT:

- n – the nonnegative integer n or a partition
- j – the number of excedances
- k – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

ValueError: invalid input, k cannot be specified
```

QuasiSymmetricFunctions.Fundamental.**antipode_on_basis**(*compo*)

Return the antipode to a Fundamental quasi-symmetric basis element.

INPUT:

- compo – composition

OUTPUT:

- The result of the antipode applied to the quasi-symmetric Fundamental basis element indexed by compo.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.antipode_on_basis(Composition([2,1]))
-F[2, 1]
```

QuasiSymmetricFunctions.Fundamental.**coproduct_on_basis**(*compo*)

Return the coproduct to a Fundamental quasi-symmetric basis element.

Combinatorial rule: quasi-deconcatenation.

INPUT:

- compo – composition

OUTPUT:

- The application of the coproduct to the Fundamental quasi-symmetric function indexed by the composition compo.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[4].coproduct()
F[] # F[4] + F[1] # F[3] + F[2] # F[2] + F[3] # F[1] + F[4] # F[]
sage: F[2,1,3].coproduct()
F[] # F[2, 1, 3] + F[1] # F[1, 1, 3] + F[2] # F[1, 3] + F[2, 1] # F[3] + F[2, 1, 1] # F[
```

TESTS:

```
sage: F.coproduct_on_basis(Composition([2,1,3]))
F[] # F[2, 1, 3] + F[1] # F[1, 1, 3] + F[2] # F[1, 3] + F[2, 1] # F[3] + F[2, 1, 1] # F[
sage: F.one().coproduct()           # generic for graded / graded connected
F[] # F[]
```

QuasiSymmetricFunctions.Fundamental.**dual**()

Return the dual basis to the Fundamental basis. This is the ribbon basis of the non-commutative symmetric functions.

OUTPUT:

•The ribbon basis of the non-commutative symmetric functions.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon basis
```

class QuasiSymmetricFunctions.**HazewinkelLambda**(*QSym*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hazewinkel lambda basis of the quasi-symmetric functions.

This basis goes back to [Haz2004], albeit it is indexed in a different way here. It is a multiplicative basis in a weak sense of this word (the product of any two basis elements is a basis element, but of course not the one obtained by concatenating the indexing compositions).

In [Haz2004], Hazewinkel showed that the $\mathbf{k}$-algebra QSym is a polynomial algebra. (The proof is correct but rests upon an unproven claim that the lexicographically largest term of the n-th shuffle power of a Lyndon word is the n-fold concatenation of this Lyndon word with itself, occurring $n!$ times in that shuffle power. But this can be deduced from Section 2 of [Rad1979]. See also Chapter 6 of [GriRei2014], specifically Theorem 6.99, for a complete proof.) More precisely, he showed that QSym is generated, as a free commutative $\mathbf{k}$-algebra, by the elements $\lambda^n(M_I)$, where n ranges over the positive integers, and I ranges over all compositions which are Lyndon words and whose entries have gcd 1. Here, λ^n denotes the n-th lambda operation as explained in lambda_of_monomial().

Thus, products of these generators form a $\mathbf{k}$-module basis of QSym. We index this basis by compositions here. More precisely, we define the Hazewinkel lambda basis $(\mathrm{HWL}_I)_I$ (with I ranging over all compositions) as follows:

Let I be a composition. Let $I = I_1 I_2 \ldots I_k$ be the Chen-Fox-Lyndon factorization of I (see lyndon_factorization()). For every $j \in \{1, 2, \ldots, k\}$, let g_j be the gcd of the entries of the Lyndon word I_j, and let J_j be the result of dividing the entries of I_j by this gcd. Then, HWL_I is defined to be $\prod_{j=1}^{k} \lambda^{g_j}(M_{J_j})$.

Todo

The conversion from the M basis to the HWL basis is currently implemented in the naive way (inverting the base-change matrix in the other direction). This matrix is not triangular (not even after any permutations of the bases), and there could very well be a faster method (the one given by Hazewinkel?).

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: HWL = QSym.HazewinkelLambda()
sage: M = QSym.M()
sage: M(HWL([2]))
M[1, 1]
sage: M(HWL([1,1]))
2*M[1, 1] + M[2]
sage: M(HWL([1,2]))
M[1, 2]
sage: M(HWL([2,1]))
3*M[1, 1, 1] + M[1, 2] + M[2, 1]
sage: M(HWL(Composition([])))
M[]
sage: HWL(M([1,1]))
HWL[2]
sage: HWL(M(Composition([2])))
HWL[1, 1] - 2*HWL[2]
sage: HWL(M([1]))
HWL[1]
```

TESTS:

Transforming from the M-basis into the HWL-basis and back returns us to where we started:

```
sage: all( M(HWL(M[I])) == M[I] for I in Compositions(3) )
True
sage: all( HWL(M(HWL[I])) == HWL[I] for I in Compositions(4) )
True
```

Checking the HWL basis elements corresponding to Lyndon words:

```
sage: all( M(HWL[Composition(I)])
....:      == M.lambda_of_monomial([i // gcd(I) for i in I], gcd(I))
....:      for I in LyndonWords(e=3, k=2) )
True
```

product_on_basis(*I*, *J*)

The product on Hazewinkel Lambda basis elements.

The product of the basis elements indexed by two compositions I and J is the basis element obtained by concatenating the Lyndon factorizations of the words I and J, then reordering the Lyndon factors in nonincreasing order, and finally concatenating them in this order (giving a new composition).

INPUT:

- I, J – compositions

OUTPUT:

- The product of the Hazewinkel Lambda quasi-symmetric functions indexed by I and J, expressed in the Hazewinkel Lambda basis.

EXAMPLES:

```
sage: HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
sage: c1 = Composition([1, 2, 1])
sage: c2 = Composition([2, 1, 3, 2])
sage: HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
sage: HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
sage: HWL.product_on_basis(Composition([]), Composition([]))
HWL[]
```

TESTS:

```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: all( all( M(HWL[I] * HWL[J]) == M(HWL[I]) * M(HWL[J])  # long time
....:           for I in Compositions(3) )
....:       for J in Compositions(3) )
True
```

class QuasiSymmetricFunctions.**Monomial**(*QSym*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of quasi-symmetric function in the Monomial basis.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,2])
M[1, 1, 1, 1] + M[1, 1, 2] + M[2, 1, 1] + M[2, 2]
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1])
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: (1+M[1])^3
M[] + 3*M[1] + 6*M[1, 1] + 6*M[1, 1, 1] + 3*M[1, 2] + 3*M[2] + 3*M[2, 1] + M[3]
sage: M[1,2,1].coproduct()
M[] # M[1, 2, 1] + M[1] # M[2, 1] + M[1, 2] # M[1] + M[1, 2, 1] # M[]
```

The following is an alias for this basis:

```
sage: QSym.Monomial()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

TESTS:

```
sage: M(F([]))
M[]
sage: M(F(0))
0
sage: M(m([]))
M[]
```

class **Element**(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Element methods of the Monomial basis of QuasiSymmetricFunctions.

expand(*n*, *alphabet='x'*)

Expand the quasi-symmetric function written in the monomial basis in n variables.

INPUT:

- n – an integer
- alphabet – (default: 'x') a string

OUTPUT:

- The quasi-symmetric function self expressed in the n variables described by alphabet.

Todo

accept an *alphabet* as input

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2].expand(3)
x0^4*x1^2 + x0^4*x2^2 + x1^4*x2^2
```

One can use a different set of variables by using the optional argument `alphabet`:

```
sage: M=QuasiSymmetricFunctions(QQ).Monomial()
sage: M[2,1,1].expand(4,alphabet='y')
y0^2*y1*y2 + y0^2*y1*y3 + y0^2*y2*y3 + y1^2*y2*y3
```

TESTS:

```
sage: (3*M([])).expand(2)
3
sage: M[4,2].expand(0)
0
sage: M([]).expand(0)
1
```

is_symmetric()

Determine if a quasi-symmetric function, written in the Monomial basis, is symmetric.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:

- `True` if `self` is an element of the symmetric functions and `False` otherwise.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).is_symmetric()
False
sage: (M[3,2] + M[2,3]).is_symmetric()
True
sage: (M[1,2,1] + M[1,1,2]).is_symmetric()
False
sage: (M[1,2,1] + M[1,1,2] + M[2,1,1]).is_symmetric()
True
```

psi_involution()

Return the image of the quasisymmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the fundamental quasisymmetric function F_I to F_{I^c}, where I^c denotes the complement of the composition I. The map ψ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution ψ of $QSym$ is adjoint to the involution ψ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also:

`psi involution on QSym`, `psi involution on NCSF`, `star involution on QSym`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].psi_involution()
```

```
-M[3, 2] - M[5]
sage: M[3,1].psi_involution()
M[3, 1] + M[4]
sage: M[3,1,1].psi_involution()
M[3, 1, 1] + M[3, 2] + M[4, 1] + M[5]
sage: M[1,1,1].psi_involution()
M[1, 1, 1] + M[1, 2] + M[2, 1] + M[3]
sage: M[[]].psi_involution()
M[]
sage: M(0).psi_involution()
0
sage: (2*M[[]] - M[3,1] + 4*M[2]).psi_involution()
2*M[] - 4*M[2] - M[3, 1] - M[4]
```

This particular implementation is tailored to the monomial basis. It is semantically equivalent to the generic implementation it overshadows:

```
sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
....:      for I in Compositions(3) )
True

sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

to_symmetric_function()

Take a quasi-symmetric function, expressed in the monomial basis, and return its symmetric realization, when possible, expressed in the monomial basis of symmetric functions.

OUTPUT:

- If `self` is a symmetric function, then the expansion in the monomial basis of the symmetric functions is returned. Otherwise an error is raised.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: M[2, 3] + M[3, 2] + M[4, 1] is not a symmetric function
sage: (M[3,2] + M[2,3] + 2*M[4,1] + 2*M[1,4]).to_symmetric_function()
m[3, 2] + 2*m[4, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1]).to_symmetric_function()
m[3, 1, 1]
sage: (M(m[2,1])*M(m[2,1])).to_symmetric_function()-m[2,1]*m[2,1]
0
```

TESTS:

```
sage: (M(0)).to_symmetric_function()
0
sage: (M([])).to_symmetric_function()
m[]
sage: (2*M([])).to_symmetric_function()
2*m[]
```

We check that the result is indexed by partitions:

```
sage: M([]).to_symmetric_function().leading_support().parent()
Partitions
```

QuasiSymmetricFunctions.Monomial.**antipode_on_basis**(*compo*)

Return the result of the antipode applied to a quasi-symmetric Monomial basis element.

INPUT:

- compo – composition

OUTPUT:

- The result of the antipode applied to the composition compo, expressed in the Monomial basis.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.antipode_on_basis(Composition([2,1]))
M[1, 2] + M[3]
sage: M.antipode_on_basis(Composition([]))
M[]
```

QuasiSymmetricFunctions.Monomial.**coproduct_on_basis**(*compo*)

Return the coproduct of a Monomial basis element.

Combinatorial rule: deconcatenation.

INPUT:

- compo – composition

OUTPUT:

- The coproduct applied to the Monomial quasi-symmetric function indexed by compo, expressed in the Monomial basis.

EXAMPLES:

```
sage: M=QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2,3].coproduct()
M[] # M[4, 2, 3] + M[4] # M[2, 3] + M[4, 2] # M[3] + M[4, 2, 3] # M[]
sage: M.coproduct_on_basis(Composition([]))
M[] # M[]
```

QuasiSymmetricFunctions.Monomial.**dual**()

Return the dual basis to the Monomial basis. This is the complete basis of the non-commutative symmetric functions.

OUTPUT:

- The complete basis of the non-commutative symmetric functions.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

QuasiSymmetricFunctions.Monomial.**lambda_of_monomial**(*I*, *n*)

Return the image of the monomial quasi-symmetric function M_I under the lambda-map λ^n, expanded in the monomial basis.

The ring of quasi-symmetric functions over the integers, $\mathrm{QSym}_{\mathbf{Z}}$ (and more generally, the ring of quasi-symmetric functions over any binomial ring) becomes a λ-ring (with the λ-structure inherited from the ring of formal power series, so that $\lambda^i(x_j)$ is x_j if $i = 1$ and 0 if $i > 1$).

The Adams operations of this λ-ring are the Frobenius endomorphisms $\mathbf{f}_n$ (see frobenius() for their definition). Using these endomorphisms, the λ-operations can be explicitly computed via the

formula

$$\exp\left(-\sum_{n=1}^{\infty}\frac{1}{n}\mathbf{f}_n(x)t^n\right)=\sum_{j=0}^{\infty}(-1)^j\lambda^j(x)t^j$$

in the ring of formal power series in a variable t over the ring of quasi-symmetric functions. In particular, every composition $I=(I_1,I_2,\cdots,I_\ell)$ satisfies

$$\exp\left(-\sum_{n=1}^{\infty}\frac{1}{n}M_{(nI_1,nI_2,\cdots,nI_\ell)}t^n\right)=\sum_{j=0}^{\infty}(-1)^j\lambda^j(M_I)t^j$$

(corrected version of Remark 2.4 in [Haz2004]).

The quasi-symmetric functions $\lambda^i(M_I)$ with n ranging over the positive integers and I ranging over the reduced Lyndon compositions (i. e., compositions which are Lyndon words and have the gcd of their entries equal to 1) form a set of free polynomial generators for QSym. See [GriRei2014], Chapter 6, for the proof, and [Haz2004] for a major part of it.

INPUT:

- `I` – composition
- `n` – nonnegative integer

OUTPUT:

The quasi-symmetric function $\lambda^n(M_I)$, expanded in the monomial basis over the ground ring of `self`.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(CyclotomicField()).Monomial()
sage: M.lambda_of_monomial([1, 2], 2)
2*M[1, 1, 2, 2] + M[1, 1, 4] + M[1, 2, 1, 2] + M[1, 3, 2] + M[2, 2, 2]
sage: M.lambda_of_monomial([1, 1], 2)
3*M[1, 1, 1, 1] + M[1, 1, 2] + M[1, 2, 1] + M[2, 1, 1]
sage: M = QuasiSymmetricFunctions(Integers(19)).Monomial()
sage: M.lambda_of_monomial([1, 2], 3)
6*M[1, 1, 1, 2, 2, 2] + 3*M[1, 1, 1, 2, 4] + 3*M[1, 1, 1, 4, 2]
+ M[1, 1, 1, 6] + 4*M[1, 1, 2, 1, 2, 2] + 2*M[1, 1, 2, 1, 4]
+ 2*M[1, 1, 2, 2, 1, 2] + 2*M[1, 1, 2, 3, 2] + 4*M[1, 1, 3, 2, 2]
+ 2*M[1, 1, 3, 4] + M[1, 1, 4, 1, 2] + M[1, 1, 5, 2]
+ 2*M[1, 2, 1, 1, 2, 2] + M[1, 2, 1, 1, 4] + M[1, 2, 1, 2, 1, 2]
+ M[1, 2, 1, 3, 2] + 4*M[1, 2, 2, 2, 2] + M[1, 2, 2, 4] + M[1, 2, 4, 2]
+ 2*M[1, 3, 1, 2, 2] + M[1, 3, 1, 4] + M[1, 3, 2, 1, 2] + M[1, 3, 3, 2]
+ M[1, 4, 2, 2] + 3*M[2, 1, 2, 2, 2] + M[2, 1, 2, 4] + M[2, 1, 4, 2]
+ 2*M[2, 2, 1, 2, 2] + M[2, 2, 1, 4] + M[2, 2, 2, 1, 2] + M[2, 2, 3, 2]
+ 2*M[2, 3, 2, 2] + M[2, 3, 4] + M[3, 2, 2, 2]
```

The map λ^0 sends everything to 1:

```
sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 0) == M.one()
....:      for I in Compositions(3) )
True
```

The map λ^1 is the identity map:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I)
....:      for I in Compositions(3) )
True
sage: M = QuasiSymmetricFunctions(Integers(5)).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I)
```

```
....:       for I in Compositions(3) )
True
sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I)
....:       for I in Compositions(3) )
True
```

QuasiSymmetricFunctions.Monomial.**product_on_basis**(*I*, *J*)

The product on Monomial basis elements.

The product of the basis elements indexed by two compositions I and J is the sum of the basis elements indexed by compositions in the stuffle product (also called the overlapping shuffle product) of I and J.

INPUT:

- I, J – compositions

OUTPUT:

- The product of the Monomial quasi-symmetric functions indexed by I and J, expressed in the Monomial basis.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: c1 = Composition([2])
sage: c2 = Composition([1,3])
sage: M.product_on_basis(c1, c2)
M[1, 2, 3] + M[1, 3, 2] + M[1, 5] + M[2, 1, 3] + M[3, 3]
sage: M.product_on_basis(c1, Composition([]))
M[2]
```

class QuasiSymmetricFunctions.**Quasisymmetric_Schur**(*QSym*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The Hopf algebra of quasi-symmetric function in the Quasisymmetric Schur basis.

The basis of Quasisymmetric Schur functions is defined in [QSCHUR] and in Definition 5.1.1 of [LMvW13]. Don't mistake them for the completely unrelated quasi-Schur functions of [NCSF1]!

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QS = QSym.QS()
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(QS[1,2])
F[1, 2]
sage: M(QS[1,2])
M[1, 1, 1] + M[1, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: QS(s[2,1,1])
QS[1, 1, 2] + QS[1, 2, 1] + QS[2, 1, 1]
```

QuasiSymmetricFunctions.**a_realization**()

Return the realization of the Monomial basis of the ring of quasi-symmetric functions.

OUTPUT:

- The Monomial basis of quasi-symmetric functions.

EXAMPLES:

```
sage: QuasiSymmetricFunctions(QQ).a_realization()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

QuasiSymmetricFunctions.**dual**()

Return the dual Hopf algebra of the quasi-symmetric functions, which is the non-commutative symmetric functions.

OUTPUT:

- The non-commutative symmetric functions.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.dual()
Non-Commutative Symmetric Functions over the Rational Field
```

class QuasiSymmetricFunctions.**dualImmaculate**(*QSym*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

The dual immaculate basis of the quasi-symmetric functions.

This basis first appears in [BBSSZ2012].

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dI()
sage: dI([1,3,2])*dI([1])  # long time (6s on sage.math, 2013)
dI[1, 1, 3, 2] + dI[2, 3, 2]
sage: dI([1,3])*dI([1,1])
dI[1, 1, 1, 3] + dI[1, 1, 4] + dI[1, 2, 3] - dI[1, 3, 2] - dI[1, 4, 1] - dI[1, 5] + dI[2, 3,
sage: dI([3,1])*dI([2,1])  # long time (7s on sage.math, 2013)
dI[1, 1, 5] - dI[1, 4, 1, 1] - dI[1, 4, 2] - 2*dI[1, 5, 1] - dI[1, 6] - dI[2, 4, 1] - dI[2,
sage: F = QSym.F()
sage: dI(F[1,3,1])
-dI[1, 1, 1, 2] + dI[1, 1, 2, 1] - dI[1, 2, 2] + dI[1, 3, 1]
sage: F(dI(F([2,1,3])))
F[2, 1, 3]
```

QuasiSymmetricFunctions.**from_polynomial**(*f*, *check=True*)

Return the quasi-symmetric function in the Monomial basis corresponding to the quasi-symmetric polynomial `f`.

INPUT:

- `f` – a polynomial in finitely many variables over the same base ring as `self`. It is assumed that this polynomial is quasi-symmetric.
- `check` – boolean (default: `True`), checks whether the polynomial is indeed quasi-symmetric.

OUTPUT:

- quasi-symmetric function in the Monomial basis

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: QSym = QuasiSymmetricFunctions(QQ)
```

```
sage: QSym.from_polynomial(f)
M[1]
```

Beware of setting `check=False`:

```
sage: f = x[0] + 2*x[1] + x[2]
sage: QSym.from_polynomial(f, check=True)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a quasi-symmetric polynomial
sage: QSym.from_polynomial(f, check=False)
M[1]
```

To expand the quasi-symmetric function in a basis other than the Monomial basis, the following shorthands are provided:

```
sage: M = QSym.Monomial()
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: g = M.from_polynomial(f); g
M[2]
sage: F = QSym.Fundamental()
sage: F(g)
-F[1, 1] + F[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

5.1.131 Introduction to Quasisymmetric Functions

In this document we briefly explain the quasisymmetric function bases and related functionality in Sage. We assume the reader is familar with the package `SymmetricFunctions`.

Quasisymmetric functions, denoted $QSym$, form a subring of the power series ring in countably many variables. $QSym$ contains the symmetric functions. These functions first arose in the theory of P-partitions. The initial ideas in this field are attributed to MacMahon, Knuth, Kreweras, Glânffrwd Thomas, Stanley. In 1984, Gessel formalized the study of quasisymmetric functions and introduced the basis of fundamental quasisymmetric functions [Ges]. In 1995, Gelfand, Krob, Lascoux, Leclerc, Retakh, and Thibon showed that the ring of quasisymmetric functions is Hopf dual to the noncommutative symmetric functions [NCSF]. Many results have built on these.

One advantage of working in $QSym$ is that many interesting families of symmetric functions have explicit expansions in fundamental quasisymmetric functions such as Schur functions [Ges], Macdonald polynomials [HHL05], and plethysm of Schur functions [LW12].

For more background see Wikipedia article Quasisymmetric_function.

To begin, initialize the ring. Below we chose to use the rational numbers $\mathbf{Q}$. Other options include the integers $\mathbf{Z}$ and $\mathbf{C}$:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym
Quasisymmetric functions over the Rational Field

sage: QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision

sage: QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

All bases of $QSym$ are indexed by compositions e.g. $[3, 1, 1, 4]$. The convention is to use capital letters for bases of $QSym$ and lowercase letters for bases of the symmetric functions Sym. Next set up names for the known bases by running `inject_shorthands()`. As with symmetric functions, you do not need to run this command and you could assign these bases other names.

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.inject_shorthands()
Injecting M as shorthand for Quasisymmetric functions over the Rational Field in the Monomial basis
Injecting F as shorthand for Quasisymmetric functions over the Rational Field in the Fundamental basi
Injecting dI as shorthand for Quasisymmetric functions over the Rational Field in the dualImmaculate
Injecting QS as shorthand for Quasisymmetric functions over the Rational Field in the Quasisymmetric
```

Now one can start constructing quasisymmetric functions.

Note: It is best to use variables other than `M` and `F`.

```
sage: x = M[2,1] + M[1,2]
sage: x
M[1, 2] + M[2, 1]

sage: y = 3*M[1,2] + M[3]^2; y
3*M[1, 2] + 2*M[3, 3] + M[6]

sage: F[3,1,3] + 7*F[2,1]
7*F[2, 1] + F[3, 1, 3]

sage: 3*F[2,1,2] + F[3]^2
F[1, 2, 2, 1] + F[1, 2, 3] + 2*F[1, 3, 2] + F[1, 4, 1] + F[1, 5] + 3*F[2, 1, 2]
 + 2*F[2, 2, 2] + 2*F[2, 3, 1] + 2*F[2, 4] + F[3, 2, 1] + 3*F[3, 3] + 2*F[4, 2] + F[5, 1] + F[6]
```

To convert from one basis to another is easy:

```
sage: z = M[1,2,1]
sage: z
M[1, 2, 1]

sage: F(z)
-F[1, 1, 1, 1] + F[1, 2, 1]

sage: M(F(z))
M[1, 2, 1]
```

To expand in variables, one can specify a finite size alphabet $x_1, x_2, \ldots, x_m$:

```
sage: y = M[1,2,1]
sage: y.expand(4)
x0*x1^2*x2 + x0*x1^2*x3 + x0*x2^2*x3 + x1*x2^2*x3
```

The usual methods on free modules are available such as coefficients, degrees, and the support:

```
sage: z=3*M[1,2]+M[3]^2; z
3*M[1, 2] + 2*M[3, 3] + M[6]

sage: z.coefficient([1,2])
3

sage: z.degree()
6
```

```
sage: sorted(z.coefficients())
[1, 2, 3]

sage: sorted(z.monomials(), key=lambda x: x.support())
[M[1, 2], M[3, 3], M[6]]

sage: z.monomial_coefficients()
{[1, 2]: 3, [3, 3]: 2, [6]: 1}
```

As with the symmetric functions package, the quasisymmetric function `1` has several instantiations. However, the most obvious way to write `1` leads to an error (this is due to the semantics of python):

```
sage: M[[]]
M[]
sage: M.one()
M[]
sage: M(1)
M[]
sage: M[[]] == 1
True
sage: M[]
Traceback (most recent call last):
...
SyntaxError: invalid syntax
```

Working with symmetric functions

The quasisymmetric functions are a ring which contains the symmetric functions as a subring. The Monomial quasisymmetric functions are related to the monomial symmetric functions by $m_\lambda = \sum_{\mathrm{sort}(c)=\lambda} M_c$, where $\mathrm{sort}(c)$ means the partition obtained by sorting the composition c:

```
sage: SymmetricFunctions(QQ).inject_shorthands()
doctest:...: RuntimeWarning: redefining global value `e`
sage: m[2,1]
m[2, 1]
sage: M(m[2,1])
M[1, 2] + M[2, 1]
sage: M(s[2,1])
2*M[1, 1, 1] + M[1, 2] + M[2, 1]
```

There are methods to test if an expression f in the quasisymmetric functions is a symmetric function:

```
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: f = M[3,1] + M[1,3]
sage: f.is_symmetric()
True
```

If f is symmetric, there are methods to convert f to an expression in the symmetric functions:

```
sage: f.to_symmetric_function()
m[3, 1]
```

The expansion of the Schur function in terms of the Fundamental quasisymmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```
sage: f = F[3,2] + F[2,2,1] + F[2,3] + F[1,3,1] + F[1,2,2]
sage: f.is_symmetric()
True
sage: f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
sage: s(f.to_symmetric_function())
s[3, 2]
```

It is also possible to convert any symmetric function to the quasisymmetric function expansion in any known basis. The converse is not true:

```
sage: M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: F( s[2,2,1] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]

sage: s(M[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= M[2, 1]) an element of self
```

It is possible to experiment with the quasisymmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

```
sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSymt = QuasiSymmetricFunctions(R)
sage: Ft = QSymt.F()
sage: Ft( Qp[2,2] )
F[1, 2, 1] + t*F[1, 3] + (t+1)*F[2, 2] + t*F[3, 1] + t^2*F[4]

sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of `F` is not equal to the base ring of `Ht`:

```
sage: F(Ht[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self (=Quasisymmetric functions ov
```

QSym is a Hopf algebra

The product on $QSym$ is commutative and is inherited from the product by the realization within the polynomial ring:

```
sage: M[3]*M[1,1] == M[1,1]*M[3]
True
sage: M[3]*M[1,1]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[3, 1, 1] + M[4, 1]
sage: F[3]*F[1,1]
F[1, 1, 3] + F[1, 2, 2] + F[1, 3, 1] + F[1, 4] + F[2, 1, 2] + F[2, 2, 1] + F[2, 3] + F[3, 1, 1] + F[
sage: M[3]*F[2]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[2, 3] + M[3, 1, 1] + M[3, 2] + M[4, 1] + M[5]
```

```
sage: F[2]*M[3]
F[1, 1, 1, 2] - F[1, 2, 2] + F[2, 1, 1, 1] - F[2, 1, 2] - F[2, 2, 1] + F[5]
```

There is a coproduct on this ring as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The co-product is non-co-commutative:

```
sage: M[1,3,1].coproduct()
M[] # M[1, 3, 1] + M[1] # M[3, 1] + M[1, 3] # M[1] + M[1, 3, 1] # M[]
sage: F[1,3,1].coproduct()
F[] # F[1, 3, 1] + F[1] # F[3, 1] + F[1, 1] # F[2, 1] + F[1, 2] # F[1, 1] + F[1, 3] # F[1] + F[1, 3,
```

The Duality Pairing with Non-Commutative Symmetric Functions

These two operations endow $QSym$ with the structure of a Hopf algebra. It is the dual Hopf algebra of the non-commutative symmetric functions $NCSF$. Under this duality, the Monomial basis of $QSym$ is dual to the Complete basis of $NCSF$, and the Fundamental basis of $QSym$ is dual to the Ribbon basis of $NCSF$ (see [MR]):

```
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1
sage: M.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: F.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[1 1 0 0 0 0 0 0]
[1 0 1 0 0 0 0 0]
[1 1 1 1 0 0 0 0]
[1 0 0 0 1 0 0 0]
[1 1 0 0 1 1 0 0]
[1 0 1 0 1 0 1 0]
[1 1 1 1 1 1 1 1]
sage: NCSF = M.realization_of().dual()
sage: R = NCSF.Ribbon()
sage: F.duality_pairing_matrix( R, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: M.duality_pairing_matrix( R, degree=4 )
[ 1  0  0  0  0  0  0  0]
[-1  1  0  0  0  0  0  0]
[-1  0  1  0  0  0  0  0]
[ 1 -1 -1  1  0  0  0  0]
[-1  0  0  0  1  0  0  0]
```

```
[ 1 -1  0  0 -1  1  0  0]
[ 1  0 -1  0 -1  0  1  0]
[-1  1  1 -1  1 -1 -1  1]
```

Let H and G be elements of $QSym$ and h an element of $NCSF$. Then if we represent the duality pairing with the mathematical notation $[\cdot, \cdot]$, we have:

$$[H \cdot G, h] = [H \otimes G, \Delta(h)].$$

For example, the coefficient of `M[2,1,4,1]` in `M[1,3]*M[2,1,1]` may be computed with the duality pairing:

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
1
```

And the coefficient of `S[1,3] # S[2,1,1]` in `S[2,1,4,1].coproduct()` is equal to this result:

```
sage: S[2,1,4,1].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing()` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if H is an element of $QSym$ and g and h are elements of $NCSF$, then

$$[H, g \cdot h] = [\Delta(H), g \otimes h].$$

For example, the coefficient of `R[2,3,1]` in `R[2,1]*R[2,1]` is computed with the duality pairing by the following command:

```
sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])
1
sage: R[2,1]*R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```

This coefficient should then be equal to the coefficient of `F[2,1] # F[2,1]` in `F[2,3,1].coproduct()`:

```
sage: F[2,3,1].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1]  + ... + F[2, 3, 1] # F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

The Operation Adjoint to Multiplication by a Non-Commutative Symmetric Function

Let $g \in NCSF$ and consider the linear endomorphism of $NCSF$ defined by left (respectively, right) multiplication by g. Since there is a duality between $QSym$ and $NCSF$, this linear transformation induces an operator $g^\perp$ on $QSym$ satisfying

$$[g^\perp(H), h] = [H, g \cdot h].$$

for any non-commutative symmetric function h.

This is implemented by the method `skew_by()`. Explicitly, if `H` is a quasisymmetric function and `g` a non-commutative symmetric function, then `H.skew_by(g)` and `H.skew_by(g, side='right')` are expressions that satisfy, for any non-commutative symmetric function `h`, the following identities:

```
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)
```

For example, `M[J].skew_by(S[I])` is 0 unless the composition J begins with I and `M(J).skew_by(S(I), side='right')` is 0 unless the composition J ends with I:

```
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism( lambda x,y: x.duality_pairing(S[3])*y )
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

The antipode

The antipode sends the Fundamental basis element indexed by the composition I to -1 to the size of I times the Fundamental basis element indexed by the conjugate composition to I:

```
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
sage: M[3,2,2].antipode()
-M[2, 2, 3] - M[2, 5] - M[4, 3] - M[7]
```

We demonstrate here the defining relation of the antipode:

```
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

class sage.combinat.ncsym.bases.**MultiplicativeNCSymBases**(*parent_with_realization*)
Bases: sage.categories.realizations.Category_realization_of_parent

Category of multiplicative bases of symmetric functions in non-commuting variables.

A multiplicative basis is one for which $\mathbf{b}_A \mathbf{b}_B = \mathbf{b}_{A|B}$ where $A|B$ is the pipe() operation on set partitions.

EXAMPLES:

```
sage: from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: MultiplicativeNCSymBases(NCSym)
Category of multiplicative bases of symmetric functions in non-commuting variables over the Rati
```

class ElementMethods

class MultiplicativeNCSymBases.**ParentMethods**

product_on_basis(*A*, *B*)
The product on basis elements.

The product on a multiplicative basis is given by $\mathbf{b}_A \cdot \mathbf{b}_B = \mathbf{b}_{A|B}$.

The bases $\{\mathbf{e}, \mathbf{h}, \mathbf{x}, \mathbf{cp}, \mathbf{p}, \mathbf{chi}, \mathbf{rho}\}$ are all multiplicative.

INPUT:
•A, B – set partitions
OUTPUT:
•an element in the basis self
EXAMPLES:

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: chi = SymmetricFunctionsNonCommutingVariables(QQ).chi()
sage: rho = SymmetricFunctionsNonCommutingVariables(QQ).rho()
sage: A = SetPartition([[1], [2, 3]])
sage: B = SetPartition([[1], [3], [2,4]])
sage: e.product_on_basis(A, B)
e{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: h.product_on_basis(A, B)
h{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: x.product_on_basis(A, B)
```

```
x{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: cp.product_on_basis(A, B)
cp{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: p.product_on_basis(A, B)
p{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: chi.product_on_basis(A, B)
chi{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: rho.product_on_basis(A, B)
rho{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: e.product_on_basis(A,B)==e(h(e(A))*h(e(B)))
True
sage: h.product_on_basis(A,B)==h(x(h(A))*x(h(B)))
True
sage: x.product_on_basis(A,B)==x(h(x(A))*h(x(B)))
True
sage: cp.product_on_basis(A,B)==cp(p(cp(A))*p(cp(B)))
True
sage: p.product_on_basis(A,B)==p(e(p(A))*e(p(B)))
True
```

MultiplicativeNCSymBases.**super_categories**()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

- a list of categories

TESTS:

```
sage: from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: MultiplicativeNCSymBases(NCSym).super_categories()
[Category of bases of symmetric functions in non-commuting variables over the Rational Field
```

class sage.combinat.ncsym.bases.**NCSymBases**(*parent_with_realization*)

Bases: sage.categories.realizations.Category_realization_of_parent

Category of bases of symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: from sage.combinat.ncsym.bases import NCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymBases(NCSym)
Category of bases of symmetric functions in non-commuting variables over the Rational Field
```

class ElementMethods

expand(*n*, *alphabet='x'*)

Expand the symmetric function into n non-commuting variables in an alphabet, which by default is 'x'.

This computation is completed by coercing the element self into the monomial basis and computing the expansion in the alphabet there.

INPUT:

- n – the number of variables in the expansion
- alphabet – (default: 'x') the alphabet in which self is to be expanded

OUTPUT:

•an expansion of `self` into the `n` non-commuting variables specified by `alphabet`

EXAMPLES:

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].expand(3)
2*x0^3 + x0^2*x1 + x0^2*x2 + 2*x0*x1*x0 + x0*x1^2 + x0*x1*x2 + 2*x0*x2*x0
 + x0*x2*x1 + x0*x2^2 + x1*x0^2 + 2*x1*x0*x1 + x1*x0*x2 + x1^2*x0 + 2*x1^3
 + x1^2*x2 + x1*x2*x0 + 2*x1*x2*x1 + x1*x2^2 + x2*x0^2 + x2*x0*x1 + 2*x2*x0*x2
 + x2*x1*x0 + x2*x1^2 + 2*x2*x1*x2 + x2^2*x0 + x2^2*x1 + 2*x2^3
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].expand(3)
-x0^2*x1 - x0^2*x2 - x0*x1^2 - x0*x1*x2 - x0*x2*x1 - x0*x2^2 - x1*x0^2
 - x1*x0*x2 - x1^2*x0 - x1^2*x2 - x1*x2*x0 - x1*x2^2 - x2*x0^2 - x2*x0*x1
 - x2*x1*x0 - x2*x1^2 - x2^2*x0 - x2^2*x1
```

internal_coproduct()

Return the internal coproduct of `self`.

The internal coproduct is defined on the power sum basis as

$$\mathbf{p}_A \mapsto \mathbf{p}_A \otimes \mathbf{p}_A$$

and the map is extended linearly.

OUTPUT:

•an element of the tensor square of the basis of `self`

EXAMPLES:

```
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 3}, {2}} + x{{1, 3}, {2}} # x{{1}, {2}, {3}}
 + x{{1, 3}, {2}} # x{{1, 3}, {2}}
```

omega()

Return the involution ω applied to `self`.

The involution ω is defined by

$$\mathbf{e}_A \mapsto \mathbf{h}_A$$

and the result is extended linearly.

OUTPUT:

•an element in the same basis as `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]].omega()
-2*m{{1, 2, 3}} - m{{1, 3}, {2}}
sage: p = NCSym.p()
sage: p[[1,3],[2]].omega()
-p{{1, 3}, {2}}
sage: cp = NCSym.cp()
sage: cp[[1,3],[2]].omega()
-2*cp{{1, 2, 3}} - cp{{1, 3}, {2}}
sage: x = NCSym.x()
sage: x[[1,3],[2]].omega()
-2*x{{1}, {2}, {3}} - x{{1, 3}, {2}}
```

to_symmetric_function()

Compute the projection of an element of symmetric function in non-commuting variables to the symmetric functions.

The projection of a monomial symmetric function in non-commuting variables indexed by the set partition A is defined as

$$\mathbf{m}_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of i in μ. For other bases this map is extended linearly.

OUTPUT:

- an element of the symmetric functions in the monomial basis

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: cp[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: x[[1,3],[2]].to_symmetric_function()
-6*m[1, 1, 1] - 2*m[2, 1]
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
```

class NCSymBases.**ParentMethods**

from_symmetric_function(*f*)

Return the image of the symmetric function f in self.

This is performed by converting to the monomial basis and extending the method sum_of_partitions() linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also:

to_symmetric_function()

INPUT:

- f – a symmetric function

OUTPUT:

- an element of self

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: Sym = SymmetricFunctions(QQ)
sage: e = NCSym.e()
sage: elem = Sym.e()
sage: elt = e.from_symmetric_function(elem[2,1,1]); elt
1/12*e{{1}, {2}, {3, 4}} + 1/12*e{{1}, {2, 3}, {4}} + 1/12*e{{1}, {2, 4}, {3}}
 + 1/12*e{{1, 2}, {3}, {4}} + 1/12*e{{1, 3}, {2}, {4}} + 1/12*e{{1, 4}, {2}, {3}}
sage: elem(elt.to_symmetric_function())
e[2, 1, 1]
sage: e.from_symmetric_function(elem[4])
1/24*e{{1, 2, 3, 4}}
```

```
sage: p = NCSym.p()
sage: pow = Sym.p()
sage: elt = p.from_symmetric_function(pow[2,1,1]); elt
1/6*p{{1}, {2}, {3, 4}} + 1/6*p{{1}, {2, 3}, {4}} + 1/6*p{{1}, {2, 4}, {3}}
 + 1/6*p{{1, 2}, {3}, {4}} + 1/6*p{{1, 3}, {2}, {4}} + 1/6*p{{1, 4}, {2}, {3}}
sage: pow(elt.to_symmetric_function())
p[2, 1, 1]
sage: p.from_symmetric_function(pow[4])
p{{1, 2, 3, 4}}
sage: h = NCSym.h()
sage: comp = Sym.complete()
sage: elt = h.from_symmetric_function(comp[2,1,1]); elt
1/12*h{{1}, {2}, {3, 4}} + 1/12*h{{1}, {2, 3}, {4}} + 1/12*h{{1}, {2, 4}, {3}}
 + 1/12*h{{1, 2}, {3}, {4}} + 1/12*h{{1, 3}, {2}, {4}} + 1/12*h{{1, 4}, {2}, {3}}
sage: comp(elt.to_symmetric_function())
h[2, 1, 1]
sage: h.from_symmetric_function(comp[4])
1/24*h{{1, 2, 3, 4}}
```

internal_coproduct()

Compute the internal coproduct of `self`.

If `internal_coproduct_on_basis()` is available, construct the internal coproduct morphism from `self` to `self` $\otimes$ `self` by extending it by linearity. Otherwise, this uses `internal_coproduct_by_coercion()`, if available.

OUTPUT:

- an element of the tensor squared of `self`

EXAMPLES:

```
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: cp.internal_coproduct(cp[[1,3],[2]] - 2*cp[[1]])
-2*cp{{1}} # cp{{1}} + cp{{1, 2, 3}} # cp{{1, 3}, {2}} + cp{{1, 3}, {2}} # cp{{1, 2, 3}}
 + cp{{1, 3}, {2}} # cp{{1, 3}, {2}}
```

internal_coproduct_by_coercion(x)

Return the internal coproduct by coercing the element to the powersum basis.

INPUT:

- `x` – an element of `self`

OUTPUT:

- an element of the tensor squared of `self`

EXAMPLES:

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].internal_coproduct() # indirect doctest
2*h{{1}, {2}, {3}} # h{{1}, {2}, {3}} - h{{1}, {2}, {3}} # h{{1, 3}, {2}}
 - h{{1, 3}, {2}} # h{{1}, {2}, {3}} + h{{1, 3}, {2}} # h{{1, 3}, {2}}
```

internal_coproduct_on_basis(i)

The internal coproduct of the algebra on the basis (optional).

INPUT:

- `i` – the indices of an element of the basis of `self`

OUTPUT:

- an element of the tensor squared of `self`

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.internal_coproduct_on_basis(SetPartition([[1,2]]))
m{{1, 2}} # m{{1, 2}}
```

primitive(*A*, *i=1*)

Return the primitive associated to `A` in `self`.

See also:

`primitive()`

INPUT:

- `A` – a set partition
- `i` – a positive integer

OUTPUT:

- an element of `self`

EXAMPLES:

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elt = e.primitive(SetPartition([[1,3],[2]])); elt
e{{1, 2}, {3}} - e{{1, 3}, {2}}
sage: elt.coproduct()
e{} # e{{1, 2}, {3}} - e{} # e{{1, 3}, {2}} + e{{1, 2}, {3}} # e{} - e{{1, 3}, {2}} # e{
```

NCSymBases.**super_categories**()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

- a list of categories

TESTS:

```
sage: from sage.combinat.ncsym.bases import NCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymBases(NCSym).super_categories()
[Category of bases of NCSym or NCSym^* over the Rational Field]
```

class sage.combinat.ncsym.bases.**NCSymBasis_abstract**(*R*, *basis_keys*, *element_class=None*, *category=None*, *prefix='B'*, ***kwds*)

Bases: `sage.combinat.free_module.CombinatorialFreeModule`, `sage.misc.bindable_class.BindableClass`

Abstract base class for a basis of $NCSym$ or its dual.

class sage.combinat.ncsym.bases.**NCSymDualBases**(*parent_with_realization*)

Bases: `sage.categories.realizations.Category_realization_of_parent`

Category of bases of dual symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: from sage.combinat.ncsym.bases import NCSymDualBases
sage: DNCSym = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymDualBases(DNCSym)
Category of bases of dual symmetric functions in non-commuting variables over the Rational Field
```

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

- a list of categories

TESTS:

```
sage: from sage.combinat.ncsym.bases import NCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymBases(NCSym).super_categories()
[Category of bases of NCSym or NCSym^* over the Rational Field]
```

class sage.combinat.ncsym.bases.**NCSymOrNCSymDualBases**(*parent_with_realization*)

Bases: sage.categories.realizations.Category_realization_of_parent

Base category for the category of bases of symmetric functions in non-commuting variables or its Hopf dual for the common code.

class ElementMethods

duality_pairing(*other*)

Compute the pairing between self and an element other of the dual.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: elt = m[[1,3],[2]] - 3*m[[1,2],[3]]
sage: elt.duality_pairing(w[[1,3],[2]])
1
sage: elt.duality_pairing(w[[1,2],[3]])
-3
sage: elt.duality_pairing(w[[1,2]])
0
sage: e = NCSym.e()
sage: w[[1,3],[2]].duality_pairing(e[[1,3],[2]])
0
```

class NCSymOrNCSymDualBases.**ParentMethods**

counit_on_basis(*A*)

The counit is defined by sending all elements of positive degree to zero.

INPUT:

- A – a set partition

OUTPUT:

- either the 0 or the 1 of the base ring of self

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: m.counit_on_basis(SetPartition([]))
1
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: w.counit_on_basis(SetPartition([]))
1
```

duality_pairing(*x*, *y*)

Compute the pairing between an element of self and an element of the dual.

Carry out this computation by converting x to the $\mathbf{m}$ basis and y to the $\mathbf{w}$ basis.

INPUT:

- x – an element of symmetric functions in non-commuting variables
- y – an element of the dual of symmetric functions in non-commuting variables

OUTPUT:

- an element of the base ring of self

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: w = NCSym.m().dual_basis()
sage: matrix([[h(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartiti
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
sage: (h[[1,2],[3]] + 3*h[[1,3],[2]]).duality_pairing(2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[
32
```

duality_pairing_matrix(*basis*, *degree*)

The matrix of scalar products between elements of $NCSym$ and elements of $NCSym^*$.

INPUT:

- basis – a basis of the dual Hopf algebra
- degree – a non-negative integer

OUTPUT:

- the matrix of scalar products between the basis self and the basis basis in the dual Hopf algebra of degree degree

EXAMPLES:

The matrix between the $\mathbf{m}$ basis and the $\mathbf{w}$ basis:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = NCSym.dual().w()
sage: m.duality_pairing_matrix(w, 3)
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

Similarly for some of the other basis of $NCSym$ and the $\mathbf{w}$ basis:

```
sage: e = NCSym.e()
sage: e.duality_pairing_matrix(w, 3)
[0 0 0 0 1]
[0 0 1 1 1]
[0 1 0 1 1]
[0 1 1 0 1]
[1 1 1 1 1]
sage: p = NCSym.p()
sage: p.duality_pairing_matrix(w, 3)
[1 0 0 0 0]
[1 1 0 0 0]
[1 0 1 0 0]
[1 0 0 1 0]
[1 1 1 1 1]
sage: cp = NCSym.cp()
sage: cp.duality_pairing_matrix(w, 3)
[1 0 0 0 0]
[1 1 0 0 0]
```

```
[0 0 1 0 0]
[1 0 0 1 0]
[1 1 1 1 1]
sage: x = NCSym.x()
sage: w.duality_pairing_matrix(x, 3)
[ 0  0  0  0  1]
[ 1  0 -1 -1  1]
[ 1 -1  0 -1  1]
[ 1 -1 -1  0  1]
[ 2 -1 -1 -1  1]
```

A base case test:

```
sage: m.duality_pairing_matrix(w, 0)
[1]
```

one_basis()

Return the index of the basis element containing 1.

OUTPUT:

- The empty set partition

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.one_basis()
{}
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.one_basis()
{}
```

NCSymOrNCSymDualBases.**super_categories**()

Return the super categories of bases of (the Hopf dual of) the symmetric functions in non-commuting variables.

OUTPUT:

- a list of categories

TESTS:

```
sage: from sage.combinat.ncsym.bases import NCSymOrNCSymDualBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymOrNCSymDualBases(NCSym).super_categories()
[Category of realizations of Symmetric functions in
  non-commuting variables over the Rational Field,
 Category of graded hopf algebras with basis over Rational Field,
 Join of Category of realizations of hopf algebras over Rational Field
  and Category of graded algebras over Rational Field]
```

5.1.135 Dual Symmetric Functions in Non-Commuting Variables

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

class sage.combinat.ncsym.dual.**SymmetricFunctionsNonCommutingVariablesDual**(*R*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The Hopf dual to the symmetric functions in non-commuting variables.

See Section 2.3 of [BZ05] for a study.

a_realization()
Return the realization of the **w** basis of `self`.

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual().a_realization()
Dual symmetric functions in non-commuting variables over the Rational Field in the w basis
```

dual()
Return the dual Hopf algebra of the dual symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymD.dual()
Symmetric functions in non-commuting variables over the Rational Field
```

class w(*NCSymD*)
Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the **w** basis.

EXAMPLES:

```
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: w = NCSymD.w()
```

We have the embedding χ^* of Sym into $NCSym^*$ available as a coercion:

```
sage: h = SymmetricFunctions(QQ).h()
sage: w(h[2,1])
w{{1}, {2, 3}} + w{{1, 2}, {3}} + w{{1, 3}, {2}}
```

Similarly we can pull back when we are in the image of χ^*:

```
sage: elt = 3*(w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]])
sage: h(elt)
3*h[2, 1]
```

class Element(*M*, *x*)
Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the **w** basis.

expand(*n*, *letter='x'*)
Expand `self` written in the **w** basis in n^2 commuting variables which satisfy the relation $x_{ij}x_{ik} = 0$ for all i, j, and k.

The expansion of an element of the **w** basis is given by equations (26) and (55) in [HNT06].

INPUT:
- `n` – an integer
- `letter` – (default: `'x'`) a string

OUTPUT:
- The symmetric function of `self` expressed in the `n*n` non-commuting variables described by `letter`.

REFERENCES:

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1,3],[2]].expand(4)
x02*x11*x20 + x03*x11*x30 + x03*x22*x30 + x13*x22*x31
```

One can use a different set of variable by using the optional argument `letter`:

```
sage: w[[1,3],[2]].expand(3, letter='y')
y02*y11*y20
```

is_symmetric()

Determine if a $NCSym^*$ function, expressed in the $\mathbf{w}$ basis, is symmetric.

A function f in the $\mathbf{w}$ basis is a symmetric function if it is in the image of χ^*. That is to say we have

$$f = \sum_{\lambda} c_\lambda \prod_i m_i(\lambda)! \sum_{\lambda(A)=\lambda} \mathbf{w}_A$$

where the second sum is over all set partitions A whose shape $\lambda(A)$ is equal to λ and $m_i(\mu)$ is the multiplicity of i in the partition μ.

OUTPUT:

- `True` if $\lambda(A) = \lambda(B)$ implies the coefficients of $\mathbf{w}_A$ and $\mathbf{w}_B$ are equal, `False` otherwise

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1])
sage: elt.is_symmetric()
True
sage: elt -= 3*w.sum_of_partitions([1,1])
sage: elt.is_symmetric()
True
sage: w = SymmetricFunctionsNonCommutingVariables(ZZ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.is_symmetric()
False
sage: elt = w[[1,3],[2]]
sage: elt.is_symmetric()
False
sage: elt = w[[1],[2,3]] + w[[1,2],[3]] + 2*w[[1,3],[2]]
sage: elt.is_symmetric()
False
```

to_symmetric_function()

Take a function in the $\mathbf{w}$ basis, and return its symmetric realization, when possible, expressed in the homogeneous basis of symmetric functions.

OUTPUT:

- If `self` is a symmetric function, then the expansion in the homogeneous basis of the symmetric functions is returned. Otherwise an error is raised.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]]
sage: elt.to_symmetric_function()
h[2, 1]
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.to_symmetric_function()
1/2*h[2, 1, 1]
```

TESTS:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w(0).to_symmetric_function()
0
sage: w([]).to_symmetric_function()
h[]
sage: (2*w([])).to_symmetric_function()
2*h[]
```

SymmetricFunctionsNonCommutingVariablesDual.w.**antipode_on_basis**(*A*)

Return the antipode applied to the basis element indexed by A.

INPUT:

- A – a set partition

OUTPUT:

- an element in the basis self

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.antipode_on_basis(SetPartition([[1],[2,3]]))
-3*w{{1}, {2}, {3}} + w{{1, 2}, {3}} + w{{1, 3}, {2}}
sage: F = w[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

SymmetricFunctionsNonCommutingVariablesDual.w.**coproduct_on_basis**(*A*)

Return the coproduct of a $\mathbf{w}$ basis element.

The coproduct on the basis element $\mathbf{w}_A$ is the sum over tensor product terms $\mathbf{w}_B \otimes \mathbf{w}_C$ where B is the restriction of A to $\{1, 2, \ldots, k\}$ and C is the restriction of A to $\{k+1, k+2, \ldots, n\}$.

INPUT:

- A – a set partition

OUTPUT:

- The coproduct applied to the $\mathbf{w}$ dual symmetric function in non-commuting variables indexed by A expressed in the $\mathbf{w}$ basis.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1], [2,3]].coproduct()
w{} # w{{1}, {2, 3}} + w{{1}} # w{{1, 2}}
 + w{{1}, {2}} # w{{1}} + w{{1}, {2, 3}} # w{}
sage: w.coproduct_on_basis(SetPartition([]))
w{} # w{}
```

SymmetricFunctionsNonCommutingVariablesDual.w.**dual_basis**()

Return the dual basis to the $\mathbf{w}$ basis.

The dual basis to the $\mathbf{w}$ basis is the monomial basis of the symmetric functions in non-commuting variables.

OUTPUT:

- the monomial basis of the symmetric functions in non-commuting variables

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.dual_basis()
Symmetric functions in non-commuting variables over the Rational Field in the monomial ba
```

SymmetricFunctionsNonCommutingVariablesDual.w.**duality_pairing**(*x*, *y*)

Compute the pairing between an element of self and an element of the dual.

INPUT:

- x – an element of the dual of symmetric functions in non-commuting variables
- y – an element of the symmetric functions in non-commuting variables

OUTPUT:

- an element of the base ring of self

EXAMPLES:

```
sage: DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
sage: w = DNCSym.w()
sage: m = w.dual_basis()
sage: matrix([[w(A).duality_pairing(m(B)) for A in SetPartitions(3)] for B in SetPartiti
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: (w[[1,2],[3]] + 3*w[[1,3],[2]]).duality_pairing(2*m[[1,3],[2]] + m[[1,2,3]] + 2*m[
8
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: matrix([[w(A).duality_pairing(h(B)) for A in SetPartitions(3)] for B in SetPartiti
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
sage: (2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[[1,2],[3]]).duality_pairing(h[[1,2],[3]] + 3*h[
32
```

SymmetricFunctionsNonCommutingVariablesDual.w.**product_on_basis**(A, B)

The product on $\mathbf{w}$ basis elements.

The product on the $\mathbf{w}$ is the dual to the coproduct on the $\mathbf{m}$ basis. On the basis $\mathbf{w}$ it is defined as

$$\mathbf{w}_A \mathbf{w}_B = \sum_{S \subseteq [n]} \mathbf{w}_{A\uparrow_S \cup B\uparrow_{S^c}}$$

where the sum is over all possible subsets S of $[n]$ such that $|S| = |A|$ with a term indexed the union of $A\uparrow_S$ and $B\uparrow_{S^c}$. The notation $A\uparrow_S$ represents the unique set partition of the set S such that the standardization is A. This product is commutative.

INPUT:

- A, B – set partitions

OUTPUT:

- an element of the $\mathbf{w}$ basis

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1, 2, 3]])
sage: w.product_on_basis(A, B)
w{{1}, {2, 3}, {4, 5, 6}} + w{{1}, {2, 3, 4}, {5, 6}}
 + w{{1}, {2, 3, 5}, {4, 6}} + w{{1}, {2, 3, 6}, {4, 5}}
 + w{{1}, {2, 4}, {3, 5, 6}} + w{{1}, {2, 4, 5}, {3, 6}}
 + w{{1}, {2, 4, 6}, {3, 5}} + w{{1}, {2, 5}, {3, 4, 6}}
 + w{{1}, {2, 5, 6}, {3, 4}} + w{{1}, {2, 6}, {3, 4, 5}}
 + w{{1, 2, 3}, {4}, {5, 6}} + w{{1, 2, 4}, {3}, {5, 6}}
 + w{{1, 2, 5}, {3}, {4, 6}} + w{{1, 2, 6}, {3}, {4, 5}}
 + w{{1, 3, 4}, {2}, {5, 6}} + w{{1, 3, 5}, {2}, {4, 6}}
 + w{{1, 3, 6}, {2}, {4, 5}} + w{{1, 4, 5}, {2}, {3, 6}}
 + w{{1, 4, 6}, {2}, {3, 5}} + w{{1, 5, 6}, {2}, {3, 4}}
sage: B = SetPartition([[1], [2]])
```

```
sage: w.product_on_basis(A, B)
3*w{{1}, {2}, {3}, {4, 5}} + 2*w{{1}, {2}, {3, 4}, {5}}
 + 2*w{{1}, {2}, {3, 5}, {4}} + w{{1}, {2, 3}, {4}, {5}}
 + w{{1}, {2, 4}, {3}, {5}} + w{{1}, {2, 5}, {3}, {4}}
sage: w.product_on_basis(A, SetPartition([]))
w{{1}, {2, 3}}
```

SymmetricFunctionsNonCommutingVariablesDual.w.**sum_of_partitions**(*la*)

Return the sum over all sets partitions whose shape is `la`, scaled by $\prod_i m_i!$ where m_i is the multiplicity of i in `la`.

INPUT:

- `la` – an integer partition

OUTPUT:

- an element of `self`

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.sum_of_partitions([2,1,1])
2*w{{1}, {2}, {3, 4}} + 2*w{{1}, {2, 3}, {4}} + 2*w{{1}, {2, 4}, {3}}
 + 2*w{{1, 2}, {3}, {4}} + 2*w{{1, 3}, {2}, {4}} + 2*w{{1, 4}, {2}, {3}}
```

SymmetricFunctionsNonCommutingVariablesDual.w.**to_symmetric_function**()

The preimage of χ^* in the **w** basis.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.to_symmetric_function
Generic morphism:
  From: Dual symmetric functions in non-commuting variables over the Rational Field in t
  To:   Symmetric Functions over Rational Field in the homogeneous basis
```

5.1.136 Symmetric Functions in Non-Commuting Variables

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

class sage.combinat.ncsym.ncsym.**SymmetricFunctionsNonCommutingVariables**(*R*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Symmetric functions in non-commutative variables.

The ring of symmetric functions in non-commutative variables, which is not to be confused with the non-commutative symmetric functions, is the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in $R\langle\langle x_1, x_2, x_3, \ldots\rangle\rangle$ of bounded degree) which are invariant with respect to the action of the symmetric group S_∞ on the indices of the indeterminates. It can be regarded as a direct limit over all $n \to \infty$ of rings of S_n-invariant polynomials in n non-commuting variables (that is, S_n-invariant elements of $R\langle x_1, x_2, \ldots, x_n\rangle$).

This ring is implemented as a Hopf algebra whose basis elements are indexed by set paritions.

Let $A = \{A_1, A_2, \ldots, A_r\}$ be a set partition of the integers $\{1, 2, \ldots, k\}$. A monomial basis element indexed by A represents the sum of monomials $x_{i_1} x_{i_2} \cdots x_{i_k}$ where $i_c = i_d$ if and only if c and d are in the same part A_i for some i.

The k-th graded component of the ring of symmetric functions in non-commutative variables has its dimension equal to the number of set partitions of k. (If we work, instead, with finitely many – say, n – variables, then its

dimension is equal to the number of set partitions of k where the number of parts is at most n.)

Note: All set partitions are considered standard, a set partition of $[n]$ for some n, unless otherwise stated.

REFERENCES:

EXAMPLES:

We begin by first creating the ring of $NCSym$ and the bases that are analogues of the usual symmetric functions:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: m
Symmetric functions in non-commuting variables over the Rational Field in the monomial basis
```

The basis is indexed by set partitions, so we create a few elements and convert them between these bases:

```
sage: elt = m(SetPartition([[1,3],[2]])) - 2*m(SetPartition([[1],[2]])); elt
-2*m{{1}, {2}} + m{{1, 3}, {2}}
sage: e(elt)
1/2*e{{1}, {2, 3}} - 2*e{{1, 2}} + 1/2*e{{1, 2}, {3}} - 1/2*e{{1, 2, 3}} - 1/2*e{{1, 3}, {2}}
sage: h(elt)
-4*h{{1}, {2}} - 2*h{{1}, {2}, {3}} + 1/2*h{{1}, {2, 3}} + 2*h{{1, 2}}
 + 1/2*h{{1, 2}, {3}} - 1/2*h{{1, 2, 3}} + 3/2*h{{1, 3}, {2}}
sage: p(elt)
-2*p{{1}, {2}} + 2*p{{1, 2}} - p{{1, 2, 3}} + p{{1, 3}, {2}}
sage: m(p(elt))
-2*m{{1}, {2}} + m{{1, 3}, {2}}

sage: elt = p(SetPartition([[1,3],[2]])) - 4*p(SetPartition([[1],[2]])) + 2; elt
2*p{} - 4*p{{1}, {2}} + p{{1, 3}, {2}}
sage: e(elt)
2*e{} - 4*e{{1}, {2}} + e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: m(elt)
2*m{} - 4*m{{1}, {2}} - 4*m{{1, 2}} + m{{1, 2, 3}} + m{{1, 3}, {2}}
sage: h(elt)
2*h{} - 4*h{{1}, {2}} - h{{1}, {2}, {3}} + h{{1, 3}, {2}}
sage: p(m(elt))
2*p{} - 4*p{{1}, {2}} + p{{1, 3}, {2}}
```

There is also a shorthand for creating elements. We note that we must use `p[[]]` to create the empty set partition due to python's syntax.

```
sage: eltm = m[[1,3],[2]] - 3*m[[1],[2]]; eltm
-3*m{{1}, {2}} + m{{1, 3}, {2}}
sage: elte = e[[1,3],[2]]; elte
e{{1, 3}, {2}}
sage: elth = h[[1,3],[2,4]]; elth
h{{1, 3}, {2, 4}}
sage: eltp = p[[1,3],[2,4]] + 2*p[[1]] - 4*p[[]]; eltp
-4*p{} + 2*p{{1}} + p{{1, 3}, {2, 4}}
```

There is also a natural projection to the usual symmetric functions by letting the variables commute. This projection map preserves the product and coproduct structure. We check that Theorem 2.1 of [RS06] holds:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sm = Sym.m()
```

```
sage: Se = Sym.e()
sage: Sh = Sym.h()
sage: Sp = Sym.p()
sage: eltm.to_symmetric_function()
-6*m[1, 1] + m[2, 1]
sage: Sm(p(eltm).to_symmetric_function())
-6*m[1, 1] + m[2, 1]
sage: elte.to_symmetric_function()
2*e[2, 1]
sage: Se(h(elte).to_symmetric_function())
2*e[2, 1]
sage: elth.to_symmetric_function()
4*h[2, 2]
sage: Sh(m(elth).to_symmetric_function())
4*h[2, 2]
sage: eltp.to_symmetric_function()
-4*p[] + 2*p[1] + p[2, 2]
sage: Sp(e(eltp).to_symmetric_function())
-4*p[] + 2*p[1] + p[2, 2]
```

a_realization()

Return the realization of the powersum basis of `self`.

OUTPUT:

- The powersum basis of symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).a_realization()
Symmetric functions in non-commuting variables over the Rational Field in the powersum basis
```

class coarse_powersum(*NCSym*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the $\mathbf{cp}$ basis.

This basis was defined in [BZ05] as

$$\mathbf{cp}_A = \sum_{A \leq_* B} \mathbf{m}_B,$$

where we sum over all strict coarsenings of the set partition A. An alternative description of this basis was given in [BT13] as

$$\mathbf{cp}_A = \sum_{A \subseteq B} \mathbf{m}_B,$$

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition A.

Note: In [BZ05], this basis was denoted by $\mathbf{q}$. In [BT13], this basis was called the powersum basis and denoted by p. However it is a coarser basis than the usual powersum basis in the sense that it does not yield the usual powersum basis of the symmetric function under the natural map of letting the variables commute.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: cp = NCSym.cp()
sage: cp[[1,3],[2,4]]*cp[[1,2,3]]
```

```
cp{{1, 3}, {2, 4}, {5, 6, 7}}
sage: cp[[1,2],[3]].internal_coproduct()
cp{{1, 2}, {3}} # cp{{1, 2}, {3}}
sage: ps = SymmetricFunctions(NCSym.base_ring()).p()
sage: ps(cp[[1,3],[2]].to_symmetric_function())
p[2, 1] - p[3]
sage: ps(cp[[1,2],[3]].to_symmetric_function())
p[2, 1]
```

class SymmetricFunctionsNonCommutingVariables.**deformed_coarse_powersum**(*NCSym*, *q=2*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the ρ basis.

This basis was defined in [BT13] as a q-deformation of the $\mathbf{cp}$ basis:

$$\rho_A = \sum_{A \subseteq B} \frac{1}{q^{\mathrm{nst}_{B-A}^{A}}} \mathbf{m}_B,$$

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition A.

INPUT:

- q – (default: 2) the parameter q

EXAMPLES:

```
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
```

We construct Example 3.1 in [BT13]:

```
sage: rnode = lambda A: sorted([a[1] for a in A.arcs()], reverse=True)
sage: dimv = lambda A: sorted([a[1]-a[0] for a in A.arcs()], reverse=True)
sage: lst = list(SetPartitions(4))
sage: S = sorted(lst, key=lambda A: (dimv(A), rnode(A)))
sage: m = NCSym.m()
sage: matrix([[m(rho[A])[B] for B in S] for A in S])
[  1   1   1   1   1   1   1   1   1   1   1   1   1   1   1]
[  0   1   0   0   1   1   0   1   0   0   1   0   0   0   0]
[  0   0   1   0   1   0   1   1   0   0   0   0   0   0   1]
[  0   0   0   1   0   1   1   1   0   0   0   1   0   0   0]
[  0   0   0   0   1   0   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   1   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   1   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   0   0   1   0   0   1   1   0   0]
[  0   0   0   0   0   0   0   0   0   1   1   0   1   0   0]
[  0   0   0   0   0   0   0   0   0   0   1   0   0   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   1   0   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   0   1   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   0   0   1 1/q]
[  0   0   0   0   0   0   0   0   0   0   0   0   0   0   1]
```

q()

Return the deformation parameter q of self.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: rho = NCSym.rho(5)
sage: rho.q()
5

sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
sage: rho.q() == q
True
```

SymmetricFunctionsNonCommutingVariables.**dual**()

Return the dual Hopf algebra of the symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual()
Dual symmetric functions in non-commuting variables over the Rational Field
```

class SymmetricFunctionsNonCommutingVariables.**elementary**(*NCSym*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the elementary basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
```

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the elementary basis of $NCSym$.

omega()

Return the involution ω applied to self.

The involution ω on $NCSym$ is defined by $\omega(\mathbf{e}_A) = \mathbf{h}_A$.

OUTPUT:

- an element in the basis self

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: elt = e[[1,3],[2]].omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: elt.omega()
e{{1, 3}, {2}}
sage: h(elt)
h{{1, 3}, {2}}
```

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the $\mathbf{e}$ basis, and return the projection of expressed in the elementary basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is given by

$$\mathbf{e}_A \mapsto e_{\lambda(A)} \prod_i \lambda(A)_i!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts.

OUTPUT:

•An element of the symmetric functions in the elementary basis

EXAMPLES:

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: e[[1],[3],[2]].to_symmetric_function()
e[1, 1, 1]
```

class SymmetricFunctionsNonCommutingVariables.**homogeneous**(*NCSym*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the homogeneous basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: h[[1,3],[2,4]]*h[[1,2,3]]
h{{1, 3}, {2, 4}, {5, 6, 7}}
sage: h[[1,2]].coproduct()
h{} # h{{1, 2}} + 2*h{{1}} # h{{1}} + h{{1, 2}} # h{}
```

class **Element**(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the homogeneous basis of $NCSym$.

omega()

Return the involution ω applied to `self`.

The involution ω on $NCSym$ is defined by $\omega(\mathbf{h}_A) = \mathbf{e}_A$.

OUTPUT:

•an element in the basis `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: e = NCSym.e()
sage: elt = h[[1,3],[2]].omega(); elt
2*h{{1}, {2}, {3}} - h{{1, 3}, {2}}
sage: elt.omega()
h{{1, 3}, {2}}
sage: e(elt)
e{{1, 3}, {2}}
```

to_symmetric_function()

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the $\mathbf{h}$ basis, and return the projection of expressed in the complete basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is given by

$$\mathbf{h}_A \mapsto h_{\lambda(A)} \prod_i \lambda(A)_i!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts.

OUTPUT:

•An element of the symmetric functions in the complete basis

EXAMPLES:

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: h[[1],[3],[2]].to_symmetric_function()
h[1, 1, 1]
```

class SymmetricFunctionsNonCommutingVariables.**monomial**(*NCSym*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the monomial basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]]*m[[1,2]]
m{{1, 3}, {2}, {4, 5}} + m{{1, 3}, {2, 4, 5}} + m{{1, 3, 4, 5}, {2}}
sage: m[[1,3],[2]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1,
 3}, {2}} # m{}
```

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the monomial basis of $NCSym$.

expand(*n*, *alphabet='x'*)

Expand self written in the monomial basis in n non-commuting variables.

INPUT:

•n – an integer

•alphabet – (default: 'x') a string

OUTPUT:

•The symmetric function of self expressed in the n non-commuting variables described by alphabet.

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].expand(4)
x0*x1*x0 + x0*x2*x0 + x0*x3*x0 + x1*x0*x1 + x1*x2*x1 + x1*x3*x1
 + x2*x0*x2 + x2*x1*x2 + x2*x3*x2 + x3*x0*x3 + x3*x1*x3 + x3*x2*x3
```

One can use a different set of variables by using the optional argument alphabet:

```
sage: m[[1],[2,3]].expand(3,alphabet='y')
y0*y1^2 + y0*y2^2 + y1*y0^2 + y1*y2^2 + y2*y0^2 + y2*y1^2
```

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the $\mathbf{m}$ basis, and return the projection of expressed in the monomial basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is defined by

$$\mathbf{m}_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of i in μ.

OUTPUT:

•an element of the symmetric functions in the monomial basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: m[[1],[3],[2]].to_symmetric_function()
6*m[1, 1, 1]
```

SymmetricFunctionsNonCommutingVariables.monomial.**coproduct_on_basis**(*A*)

Return the coproduct of a monomial basis element.

INPUT:

•A – a set partition

OUTPUT:

•The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1, 3], [2]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3}, {2}} # m{}
sage: m.coproduct_on_basis(SetPartition([]))
m{} # m{}
sage: m.coproduct_on_basis(SetPartition([[1,2,3]]))
m{} # m{{1, 2, 3}} + m{{1, 2, 3}} # m{}
sage: m[[1,5],[2,4],[3,7],[6]].coproduct()
m{} # m{{1, 5}, {2, 4}, {3, 7}, {6}} + m{{1}} # m{{1, 5}, {2, 4}, {3, 6}}
 + 2*m{{1, 2}} # m{{1, 3}, {2, 5}, {4}} + m{{1, 2}} # m{{1, 4}, {2, 3}, {5}}
 + 2*m{{1, 2}, {3}} # m{{1, 3}, {2, 4}} + m{{1, 3}, {2}} # m{{1, 4}, {2, 3}}
 + 2*m{{1, 3}, {2, 4}} # m{{1, 2}, {3}} + 2*m{{1, 3}, {2, 5}, {4}} # m{{1, 2}}
 + m{{1, 4}, {2, 3}} # m{{1, 3}, {2}} + m{{1, 4}, {2, 3}, {5}} # m{{1, 2}}
 + m{{1, 5}, {2, 4}, {3, 6}} # m{{1}} + m{{1, 5}, {2, 4}, {3, 7}, {6}} # m{}
```

SymmetricFunctionsNonCommutingVariables.monomial.**dual_basis**()

Return the dual basis to the monomial basis.

OUTPUT:

•the w basis of the dual Hopf algebra

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.dual_basis()
Dual symmetric functions in non-commuting variables over the Rational Field in the w bas
```

SymmetricFunctionsNonCommutingVariables.monomial.**duality_pairing**(*x*, *y*)

Compute the pairing between an element of self and an element of the dual.

INPUT:

•x – an element of symmetric functions in non-commuting variables

•y – an element of the dual of symmetric functions in non-commuting variables

OUTPUT:

•an element of the base ring of self

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
```

```
sage: w = m.dual_basis()
sage: matrix([[m(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartiti
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: (m[[1,2],[3]] + 3*m[[1,3],[2]]).duality_pairing(2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[
8
```

SymmetricFunctionsNonCommutingVariables.monomial.**from_symmetric_function**(f)

Return the image of the symmetric function `f` in `self`.

This is performed by converting to the monomial basis and extending the method `sum_of_partitions()` linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also:

`to_symmetric_function()`

INPUT:

- `f` – an element of the symmetric functions

OUTPUT:

- An element of the $\mathbf{m}$ basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: mon = SymmetricFunctions(QQ).m()
sage: elt = m.from_symmetric_function(mon[2,1,1]); elt
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4}, {3}}
 + 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4}, {2}, {3}}
sage: elt.to_symmetric_function()
m[2, 1, 1]
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elm = SymmetricFunctions(QQ).e()
sage: e(m.from_symmetric_function(elm[4]))
1/24*e{{1, 2, 3, 4}}
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: hom = SymmetricFunctions(QQ).h()
sage: h(m.from_symmetric_function(hom[4]))
1/24*h{{1, 2, 3, 4}}
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: pow = SymmetricFunctions(QQ).p()
sage: p(m.from_symmetric_function(pow[4]))
p{{1, 2, 3, 4}}
sage: p(m.from_symmetric_function(pow[2,1]))
1/3*p{{1}, {2, 3}} + 1/3*p{{1, 2}, {3}} + 1/3*p{{1, 3}, {2}}
sage: p([[1,2]])*p([[1]])
p{{1, 2}, {3}}
```

Check that $\chi \circ \widetilde{\chi}$ is the identity on Sym:

```
sage: all(m.from_symmetric_function(pow(la)).to_symmetric_function() == pow(la)
....:     for la in Partitions(4))
True
```

SymmetricFunctionsNonCommutingVariables.monomial.**internal_coproduct_on_basis**(A)

Return the internal coproduct of a monomial basis element.

The internal coproduct is defined by

$$\Delta^{\odot}(\mathbf{m}_A) = \sum_{B \wedge C = A} \mathbf{m}_B \otimes \mathbf{m}_C$$

where we sum over all pairs of set partitions B and C whose infimum is A.

INPUT:

•A – a set partition

OUTPUT:

•an element of the tensor square of the $\mathbf{m}$ basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
m{{1, 2, 3}} # m{{1, 3}, {2}} + m{{1, 3}, {2}} # m{{1, 2, 3}} + m{{1, 3}, {2}} # m{{1, 3
```

SymmetricFunctionsNonCommutingVariables.monomial.**product_on_basis**(*A*, *B*)

The product on monomial basis elements.

The product of the basis elements indexed by two set partitions A and B is the sum of the basis elements indexed by set partitions C such that $C \wedge ([n]|[k]) = A|B$ where $n = |A|$ and $k = |B|$. Here $A \wedge B$ is the infimum of A and B and $A|B$ is the `SetPartition.pipe()` operation. Equivalently we can describe all C as matchings between the partitions of A and B where if $a \in A$ is matched with $b \in B$, we take $a \cup b$ instead of a and b in C.

INPUT:

•A, B – set partitions

OUTPUT:

•an element of the $\mathbf{m}$ basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1], [3], [2,4]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5, 7}, {6}} + m{{1}, {2, 3, 4}, {5, 7}, {6}}
 + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}}
 + m{{1, 4}, {2, 3}, {5, 7}, {6}} + m{{1, 4}, {2, 3, 5, 7}, {6}}
 + m{{1, 4}, {2, 3, 6}, {5, 7}} + m{{1, 5, 7}, {2, 3}, {4}, {6}}
 + m{{1, 5, 7}, {2, 3, 4}, {6}} + m{{1, 5, 7}, {2, 3, 6}, {4}}
 + m{{1, 6}, {2, 3}, {4}, {5, 7}} + m{{1, 6}, {2, 3, 4}, {5, 7}}
 + m{{1, 6}, {2, 3, 5, 7}, {4}}
sage: B = SetPartition([[1], [2]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}}
 + m{{1}, {2, 3, 5}, {4}} + m{{1, 4}, {2, 3}, {5}} + m{{1, 4}, {2, 3, 5}}
 + m{{1, 5}, {2, 3}, {4}} + m{{1, 5}, {2, 3, 4}}
sage: m.product_on_basis(A, SetPartition([]))
m{{1}, {2, 3}}
```

TESTS:

We check that we get all of the correct set partitions:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1], [2]])
sage: S = SetPartition([[1,2,3], [4,5]])
sage: AB = SetPartition([[1], [2,3], [4], [5]])
sage: L = sorted(filter(lambda x: S.inf(x) == AB, SetPartitions(5)), key=str)
```

```
sage: map(list, L) == map(list, sorted(m.product_on_basis(A, B).support(), key=str))
True
```

SymmetricFunctionsNonCommutingVariables.monomial.**sum_of_partitions**(*la*)

Return the sum over all set partitions whose shape is `la` with a fixed coefficient C defined below.

Fix a partition λ, we define $\lambda! := \prod_i \lambda_i!$ and $\lambda^! := \prod_i m_i!$. Recall that $|\lambda| = \sum_i \lambda_i$ and m_i is the number of parts of length i of λ. Thus we defined the coefficient as

$$C := \frac{\lambda!\lambda^!}{|\lambda|!}.$$

Hence we can define a lift $\widetilde{\chi}$ from Sym to $NCSym$ by

$$m_\lambda \mapsto C \sum_A \mathbf{m}_A$$

where the sum is over all set partitions whose shape is λ.

INPUT:

- `la` – an integer partition

OUTPUT:

- an element of the $\mathbf{m}$ basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.sum_of_partitions(Partition([2,1,1]))
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4}, {3}}
 + 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4}, {2}, {3}}
```

TESTS:

Check that $\chi \circ \widetilde{\chi}$ is the identity on Sym:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: mon = SymmetricFunctions(QQ).monomial()
sage: all(m.from_symmetric_function(mon[la]).to_symmetric_function() == mon[la]
....:     for i in range(6) for la in Partitions(i))
True
```

class SymmetricFunctionsNonCommutingVariables.**powersum**(*NCSym*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the powersum basis.

The powersum basis is given by

$$\mathbf{p}_A = \sum_{A \leq B} \mathbf{m}_B,$$

where we sum over all coarsenings of the set partition A. If we allow our variables to commute, then $\mathbf{p}_A$ goes to the usual powersum symmetric function p_λ whose (integer) partition λ is the shape of A.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: p = NCSym.p()

sage: x = p.an_element()**2; x
4*p{} + 8*p{{1}} + 4*p{{1}, {2}} + 6*p{{1}, {2, 3}}
 + 12*p{{1, 2}} + 6*p{{1, 2}, {3}} + 9*p{{1, 2}, {3, 4}}
sage: x.to_symmetric_function()
4*p[] + 8*p[1] + 4*p[1, 1] + 12*p[2] + 12*p[2, 1] + 9*p[2, 2]
```

class Element(M, x)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element in the powersum basis of $NCSym$.

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the $\mathbf{p}$ basis, and return the projection of expressed in the powersum basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is given by

$$\mathbf{p}_A \mapsto p_{\lambda(A)}$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts.

OUTPUT:

•an element of symmetric functions in the power sum basis

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
sage: p[[1],[3],[2]].to_symmetric_function()
p[1, 1, 1]
```

SymmetricFunctionsNonCommutingVariables.powersum.**antipode_on_basis**(A)

Return the result of the antipode applied to a powersum basis element.

Let A be a set partition. The antipode given in [LM2011] is

$$S(\mathbf{p}_A) = \sum_{\gamma} (-1)^{\ell(\gamma)} \mathbf{p}_{\gamma[A]}$$

where we sum over all ordered set partitions (i.e. set compositions) of $[\ell(A)]$ and

$$\gamma[A] = A^{\downarrow}_{\gamma_1} | \cdots | A^{\downarrow}_{\gamma_{\ell(A)}}$$

is the action of γ on A defined in SetPartition.ordered_set_partition_action().

INPUT:

•A – a set partition

OUTPUT:

•an element in the basis self

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.antipode_on_basis(SetPartition([[1], [2,3]]))
p{{1, 2}, {3}}
sage: p.antipode_on_basis(SetPartition([]))
p{}
sage: F = p[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

SymmetricFunctionsNonCommutingVariables.powersum.**coproduct_on_basis**(A)

Return the coproduct of a monomial basis element.

INPUT:

•A – a set partition

OUTPUT:

•The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p[[1, 3], [2]].coproduct()
p{} # p{{1, 3}, {2}} + p{{1}} # p{{1, 2}} + p{{1, 2}} # p{{1}} + p{{1, 3}, {2}} # p{}
sage: p.coproduct_on_basis(SetPartition([[1]]))
p{} # p{{1}} + p{{1}} # p{}
sage: p.coproduct_on_basis(SetPartition([]))
p{} # p{}
```

SymmetricFunctionsNonCommutingVariables.powersum.**internal_coproduct_on_basis**(*A*)

Return the internal coproduct of a powersum basis element.

The internal coproduct is defined by

$$\Delta^{\odot}(\mathbf{p}_A) = \mathbf{p}_A \otimes \mathbf{p}_A$$

INPUT:

•A – a set partition

OUTPUT:

•an element of the tensor square of self

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
p{{1, 3}, {2}} # p{{1, 3}, {2}}
```

SymmetricFunctionsNonCommutingVariables.powersum.**primitive**(*A*, *i=1*)

Return the primitive associated to A in self.

Fix some $i \in S$. Let A be an atomic set partition of S, then the primitive $p(A)$ given in [LM2011] is

$$p(A) = \sum_{\gamma} (-1)^{\ell(\gamma)-1} \mathbf{p}_{\gamma[A]}$$

where we sum over all ordered set partitions of $[\ell(A)]$ such that $i \in \gamma_1$ and $\gamma[A]$ is the action of γ on A defined in SetPartition.ordered_set_partition_action(). If A is not atomic, then $p(A) = 0$.

See also:

SetPartition.is_atomic()

INPUT:

•A – a set partition

•i – (default: 1) index in the base set for A specifying which set of primitives this belongs to

OUTPUT:

•an element in the basis self

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: elt = p.primitive(SetPartition([[1,3], [2]])); elt
-p{{1, 2}, {3}} + p{{1, 3}, {2}}
sage: elt.coproduct()
-p{} # p{{1, 2}, {3}} + p{} # p{{1, 3}, {2}} - p{{1, 2}, {3}} # p{} + p{{1, 3}, {2}} # p
sage: p.primitive(SetPartition([[1], [2,3]]))
0
sage: p.primitive(SetPartition([]))
p{}
```

SymmetricFunctionsNonCommutingVariables.**q**()
Old name for the **cp**-basis. Deprecated in trac ticket #18371.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSym.q()
doctest:...: DeprecationWarning: q is deprecated, use instead cp or coarse_powersum.
See http://trac.sagemath.org/18371 for details.
Symmetric functions in non-commuting variables over the Rational Field in the coarse_powersu
```

class SymmetricFunctionsNonCommutingVariables.**supercharacter**(*NCSym*, *q=2*)
Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the supercharacter χ basis.

This basis was defined in [BT13] as a q-deformation of the supercharacter basis.

$$\chi_A = \sum_B \chi_A(B)\mathbf{m}_B,$$

where we sum over all set partitions A and $\chi_A(B)$ is the evaluation of the supercharacter χ_A on the superclass μ_B.

Note: The supercharacters considered in [BT13] are coarser than those considered by Aguiar et. al.

INPUT:

- q – (default: 2) the parameter q

EXAMPLES:

```
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi[[1,3],[2]]*chi[[1,2]]
chi{{1, 3}, {2}, {4, 5}}
sage: chi[[1,3],[2]].coproduct()
chi{} # chi{{1, 3}, {2}} + (2*q-2)*chi{{1}} # chi{{1}, {2}} +
 (3*q-2)*chi{{1}} # chi{{1, 2}} + (2*q-2)*chi{{1}, {2}} # chi{{1}} +
 (3*q-2)*chi{{1, 2}} # chi{{1}} + chi{{1, 3}, {2}} # chi{}
sage: chi2 = NCSym.chi()
sage: chi(chi2[[1,2],[3]])
((-q+2)/q)*chi{{1}, {2}, {3}} + 2/q*chi{{1, 2}, {3}}
sage: chi2
Symmetric functions in non-commuting variables over the Fraction Field
 of Univariate Polynomial Ring in q over Rational Field in the
 supercharacter basis with parameter q=2
```

q()
Return the deformation parameter q of self.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: chi = NCSym.chi(5)
sage: chi.q()
5

sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
```

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi.q() == q
True
```

class SymmetricFunctionsNonCommutingVariables.**x_basis**(*NCSym*)

Bases: sage.combinat.ncsym.bases.NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the $\mathbf{x}$ basis.

This basis is defined in [BHRZ06] by the formula:

$$\mathbf{x}_A = \sum_{B \leq A} \mu(B, A) \mathbf{p}_B$$

and has the following properties:

$$\mathbf{x}_A \mathbf{x}_B = \mathbf{x}_{A|B}, \qquad \Delta^{\odot}(\mathbf{x}_C) = \sum_{A \vee B = C} \mathbf{x}_A \otimes \mathbf{x}_B.$$

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: x = NCSym.x()
sage: x[[1,3],[2,4]]*x[[1,2,3]]
x{{1, 3}, {2, 4}, {5, 6, 7}}
sage: x[[1,2],[3]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 2}, {3}} + x{{1, 2}, {3}} # x{{1}, {2}, {3}} +
 x{{1, 2}, {3}} # x{{1, 2}, {3}}
```

sage.combinat.ncsym.ncsym.**matchings**(*A*, *B*)

Iterate through all matchings of the sets A and B.

EXAMPLES:

```
sage: from sage.combinat.ncsym.ncsym import matchings
sage: list(matchings([1, 2, 3], [-1, -2]))
[[[1], [2], [3], [-1], [-2]],
 [[1], [2], [3, -1], [-2]],
 [[1], [2], [3, -2], [-1]],
 [[1], [2, -1], [3], [-2]],
 [[1], [2, -1], [3, -2]],
 [[1], [2, -2], [3], [-1]],
 [[1], [2, -2], [3, -1]],
 [[1, -1], [2], [3], [-2]],
 [[1, -1], [2], [3, -2]],
 [[1, -1], [2, -2], [3]],
 [[1, -2], [2], [3], [-1]],
 [[1, -2], [2], [3, -1]],
 [[1, -2], [2, -1], [3]]]
```

sage.combinat.ncsym.ncsym.**nesting**(*la*, *nu*)

Return the nesting number of `la` inside of `nu`.

If we consider a set partition A as a set of arcs $i - j$ where i and j are in the same part of A. Define

$$\mathrm{nst}_{\lambda}^{\nu} = \#\{i < j < k < l \mid i - l \in \nu, j - k \in \lambda\},$$

and this corresponds to the number of arcs of λ strictly contained inside of ν.

EXAMPLES:

```
sage: from sage.combinat.ncsym.ncsym import nesting
sage: nu = SetPartition([[1,4], [2], [3]])
sage: mu = SetPartition([[1,4], [2,3]])
sage: nesting(set(mu).difference(nu), nu)
1
```

```
sage: lst = list(SetPartitions(4))
sage: d = {}
sage: for i, nu in enumerate(lst):
....:     for mu in nu.coarsenings():
....:         if set(nu.arcs()).issubset(mu.arcs()):
....:             d[i, lst.index(mu)] = nesting(set(mu).difference(nu), nu)
sage: matrix(d)
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]

```

5.1.137 Necklaces

The algorithm used in this file comes from

- Sawada, Joe. "A fast algorithm to generate necklaces with fixed content", Source Theoretical Computer Science archive Volume 301 , Issue 1-3 (May 2003)

`sage.combinat.necklace.`**`Necklaces`**(*content*)

Return the combinatorial class of necklaces with evaluation `content`.

A necklace is a list of integers that such that the list is the smallest lexicographic representative of all the cyclic shifts of the list.

See also:

`LyndonWords`

INPUT:

- `content` – a list of non-negative integers

EXAMPLES:

```
sage: Necklaces([2,1,1])
Necklaces with evaluation [2, 1, 1]
sage: Necklaces([2,1,1]).cardinality()
3
sage: Necklaces([2,1,1]).first()
[1, 1, 2, 3]
sage: Necklaces([2,1,1]).last()
[1, 2, 1, 3]
```

```
sage: Necklaces([2,1,1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
sage: Necklaces([0,2,1,1]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
sage: Necklaces([2,0,1,1]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

class sage.combinat.necklace.**Necklaces_evaluation**(*content*)

Bases: sage.combinat.combinat.CombinatorialClass

Necklaces with a fixed evaluation (content).

INPUT:

- content – a list of non-negative integers

cardinality()

Return the number of integer necklaces with the evaluation content.

The formula for the number of necklaces of content α a composition of n is:

$$\sum_{d|gcd(\alpha)} \phi(d) \binom{n/d}{\alpha_1/d, \ldots, \alpha_\ell/d},$$

where $\phi(d)$ is the Euler ϕ function.

EXAMPLES:

```
sage: Necklaces([]).cardinality()
0
sage: Necklaces([2,2]).cardinality()
2
sage: Necklaces([2,3,2]).cardinality()
30
sage: Necklaces([0,3,2]).cardinality()
2
```

Check to make sure that the count matches up with the number of necklace words generated.

```
sage: comps = [[],[2,2],[3,2,7],[4,2],[0,4,2],[2,0,4]]+Compositions(4).list()
sage: ns = [ Necklaces(comp) for comp in comps]
sage: all( [ n.cardinality() == len(n.list()) for n in ns] )
True
```

content()

Return the content (or evaluation) of the necklaces.

TESTS:

```
sage: N = Necklaces([2,2,2])
sage: N.content()
[2, 2, 2]
```

e()

Deprecated in trac ticket #17436. Use content() instead.

TESTS:

```
sage: N = Necklaces([2,2,2])
sage: N.e
doctest:...: DeprecationWarning: e attribute is deprecated. Use the content method instead
```

```
See http://trac.sagemath.org/17436 for details.
[2, 2, 2]
```

5.1.138 Non-Decreasing Parking Functions

A *non-decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size n is the n-th Catalan number.

The set of non-decreasing parking functions of size n is in bijection with the set of Dyck words of size n.

AUTHORS:

- Florent Hivert (2009-04)
- Christian Stump (2012-11) added pretty printing

class sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunction**(*lst*)

Bases: sage.combinat.combinat.CombinatorialObject

A *non decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

EXAMPLES:

```
sage: NonDecreasingParkingFunction([])
[]
sage: NonDecreasingParkingFunction([1])
[1]
sage: NonDecreasingParkingFunction([2])
Traceback (most recent call last):
...
ValueError: [2] is not a non-decreasing parking function
sage: NonDecreasingParkingFunction([1,2])
[1, 2]
sage: NonDecreasingParkingFunction([1,1,2])
[1, 1, 2]
sage: NonDecreasingParkingFunction([1,1,4])
Traceback (most recent call last):
...
ValueError: [1, 1, 4] is not a non-decreasing parking function
```

classmethod from_dyck_word(*dw*)

Bijection from Dyck words. It is the inverse of the bijection to_dyck_word(). You can find there the mathematical definition.

EXAMPLES:

```
sage: NonDecreasingParkingFunction.from_dyck_word([])
[]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0])
[1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,1,0,0])
[1, 1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,0])
[1, 2]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,1,0,1,0,0,1,0])
[1, 2, 2, 3, 5]
```

TESTS:

```
sage: ndpf=NonDecreasingParkingFunctions(5);
sage: list(ndpf) == [NonDecreasingParkingFunction.from_dyck_word(pf.to_dyck_word()) for pf i
True
```

to_dyck_word()

Implements the bijection to Dyck words, which is defined as follows. Take a non decreasing parking function, say [1,1,2,4,5,5], and draw its graph:

```
          ___
         |  . 5
        _|  . 5
    ___|  . . 4
 _|  . . . . 2
|  . . . . . 1
|  . . . . . 1
```

The corresponding Dyck word [1,1,0,1,0,0,1,0,1,1,0,0] is then read off from the sequence of horizontal and vertical steps. The converse bijection is from_dyck_word().

EXAMPLES:

```
sage: NonDecreasingParkingFunction([1,1,2,4,5,5]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 0]
sage: NonDecreasingParkingFunction([]).to_dyck_word()
[]
sage: NonDecreasingParkingFunction([1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0]
sage: NonDecreasingParkingFunction([1,2,3]).to_dyck_word()
[1, 0, 1, 0, 1, 0]
sage: NonDecreasingParkingFunction([1,1,3,3,4,6,6]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

TESTS:

```
sage: ndpf=NonDecreasingParkingFunctions(5);
sage: list(ndpf) == [pf.to_dyck_word().to_non_decreasing_parking_function() for pf in ndpf]
True
```

sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunctions**(*n=None*)

Returns the combinatorial class of Non-Decreasing Parking Functions.

A *non-decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

EXAMPLES:

Here are all the-non decreasing parking functions of size 5:

```
sage: NonDecreasingParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
```

If no size is specified, then NonDecreasingParkingFunctions returns the combinatorial class of all non-decreasing parking functions.

```
sage: PF = NonDecreasingParkingFunctions(); PF
Non-decreasing parking functions
sage: [] in PF
True
sage: [1] in PF
True
sage: [2] in PF
```

```
False
sage: [1,1,3] in PF
True
sage: [1,1,4] in PF
False
```

If the size n is specified, then NonDecreasingParkingFunctions returns combinatorial class of all non-decreasing parking functions of size n.

```
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.list()
[[]]
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]

sage: PF3 = NonDecreasingParkingFunctions(3); PF3
Non-decreasing parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,1,3] in PF3
True
sage: [1,1,4] in PF3
False
```

TESTS:

```
sage: PF = NonDecreasingParkingFunctions(5)
sage: len(PF.list()) == PF.cardinality()
True
sage: NonDecreasingParkingFunctions("foo")
Traceback (most recent call last):
...
TypeError: unable to convert 'foo' to an integer
```

class sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunctions_all**

Bases: sage.combinat.combinat.InfiniteAbstractCombinatorialClass

TESTS:

```
sage: DW = NonDecreasingParkingFunctions()
sage: DW == loads(dumps(DW))
True
```

class sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunctions_n**(n)

Bases: sage.combinat.combinat.CombinatorialClass

The combinatorial class of non-decreasing parking functions of size n.

A *non-decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size n is the n-th Catalan number.

EXAMPLES:

```
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
sage: PF = NonDecreasingParkingFunctions(4)
sage: PF.list()
[[1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 1, 3], [1, 1, 1, 4], [1, 1, 2, 2], [1, 1, 2, 3], [1, 1, 2, 4
sage: [ NonDecreasingParkingFunctions(i).cardinality() for i in range(10)]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

Warning: The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

AUTHORS:

•Florent Hivert

cardinality()

Returns the number of non-decreasing parking functions of size n. This number is the n-th Catalan number.

EXAMPLES:

```
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.cardinality()
5
sage: PF = NonDecreasingParkingFunctions(5)
sage: PF.cardinality()
42
```

sage.combinat.non_decreasing_parking_function.**is_a**(*x*, *n=None*)

Check whether a list is a non-decreasing parking function. If a size n is specified, checks if a list is a non-decreasing parking function of size n.

TESTS:

```
sage: from sage.combinat.non_decreasing_parking_function import is_a
sage: is_a([1,1,2])
True
sage: is_a([1,1,4])
False
sage: is_a([1,1,3], 3)
True
```

5.1.139 Ordered Rooted Trees

AUTHORS:

- Florent Hivert (2010-2011): initial revision
- Frederic Chapoton (2010): contributed some methods

class sage.combinat.ordered_tree.**LabelledOrderedTree**(*parent*, *children*, *label=None*, *check=True*)

Bases: sage.combinat.abstract_tree.AbstractLabelledClonableTree, sage.combinat.ordered_tree.OrderedTree

Labelled ordered trees.

A labelled ordered tree is an ordered tree with a label attached at each node.

INPUT:

- children – a list or tuple or more generally any iterable of trees or object convertible to trees
- label – any Sage object (default: None)

EXAMPLES:

```
sage: x = LabelledOrderedTree([], label = 3); x
3[]
sage: LabelledOrderedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledOrderedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledOrderedTree([[],[[], []]], label = 3)
3[None[], None[None[], None[]]]
```

left_right_symmetry()

Return the symmetric tree of self.

The symmetric tree $s(T)$ of a labelled ordered tree T is defined as follows: If T is a labelled ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of T is a labelled ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right), and with the same root label as T.

Note: If you have a subclass of LabelledOrderedTree() which also inherits from another subclass of OrderedTree() which does not come with a labelling, then (depending on the method resolution order) it might happen that this method gets overridden by an implementation from that other subclass, and thus forgets about the labels. In this case you need to manually override this method on your subclass.

EXAMPLES:

```
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.left_right_symmetry()
4[3[], 2[]]
sage: T223 = LabelledOrderedTree([L2, T23], label=17)
sage: T223.left_right_symmetry()
17[4[3[], 2[]], 2[]]
sage: T223.left_right_symmetry().left_right_symmetry() == T223
True
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled tree self.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the labelled tree uniquely, and can be used to sort the labelled ordered trees provided that the labels belong to a type which is totally ordered.

Warning: This method overrides `OrderedTree.sort_key()` and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `LabelledOrderedTree`; under some circumstances they could inherit it from another superclass instead of from `OrderedTree`, which would cause the method to forget the labelling. See the docstring of `OrderedTree.sort_key()`.

EXAMPLES:

```
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.sort_key()
((2, 4), (0, 2), (0, 3))
sage: T32 = LabelledOrderedTree([L3, L2], label=5)
sage: T32.sort_key()
((2, 5), (0, 3), (0, 2))
sage: T23322 = LabelledOrderedTree([T23, T32, L2], label=14)
sage: T23322.sort_key()
((3, 14), (2, 4), (0, 2), (0, 3), (2, 5), (0, 3), (0, 2), (0, 2))
```

class sage.combinat.ordered_tree.**LabelledOrderedTrees**(*category=None*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

This is a parent stub to serve as a factory class for trees with various label constraints.

EXAMPLES:

```
sage: LOT = LabelledOrderedTrees(); LOT
Labelled ordered trees
sage: x = LOT([], label = 3); x
3[]
sage: x.parent() is LOT
True
sage: y = LOT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LOT
True
```

Element

alias of `LabelledOrderedTree`

cardinality()

Return the cardinality of `self`.

EXAMPLE:

```
sage: LabelledOrderedTrees().cardinality()
+Infinity
```

labelled_trees()

Return the set of labelled trees associated to `self`.

This is precisely `self`, because `self` already is the set of labelled ordered trees.

EXAMPLES:

```
sage: LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
sage: LOT = LabelledOrderedTrees()
```

```
sage: x = LOT([], label = 3)
sage: y = LOT([x, x, x], label = 2)
sage: y.canonical_labelling()
1[2[], 3[], 4[]]
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

This is the set of ordered trees, since `self` is the set of labelled ordered trees.

EXAMPLES:

```
sage: LabelledOrderedTrees().unlabelled_trees()
Ordered trees
```

class sage.combinat.ordered_tree.**OrderedTree**(*parent=None*, *children=[]*, *check=True*)

Bases: sage.combinat.abstract_tree.AbstractClonableTree, sage.structure.list_clone.ClonableList

The class of (ordered rooted) trees.

An ordered tree is constructed from a node, called the root, on which one has grafted a possibly empty list of trees. There is a total order on the children of a node which is given by the order of the elements in the list. Note that there is no empty ordered tree (so the smallest ordered tree consists of just one node).

INPUT:

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree. Alternatively a string is also accepted. The syntax is the same as for printing: children are grouped by square brackets.

EXAMPLES:

```
sage: x = OrderedTree([])
sage: x1 = OrderedTree([x,x])
sage: x2 = OrderedTree([[],[]])
sage: x1 == x2
True
sage: tt1 = OrderedTree([x,x1,x2])
sage: tt2 = OrderedTree([[], [[], []], x2])
sage: tt1 == tt2
True

sage: OrderedTree([]) == OrderedTree()
True
```

TESTS:

```
sage: x1.__hash__() == x2.__hash__()
True
sage: tt1.__hash__() == tt2.__hash__()
True
```

Trees are usually immutable. However they inherit from `sage.structure.list_clone.ClonableList`, so that they can be modified using the clone protocol. Let us now see what this means.

Trying to modify a non-mutable tree raises an error:

```
sage: tt1[1] = tt2
Traceback (most recent call last):
...
ValueError: object is immutable; please change a copy instead.
```

Here is the correct way to do it:

```
sage: with tt2.clone() as tt2:
....:     tt2[1] = tt1
sage: tt2
[[], [[], [[], []], [[], []]], [[], []]]
```

It is also possible to append a child to a tree:

```
sage: with tt2.clone() as tt3:
....:     tt3.append(OrderedTree([]))
sage: tt3
[[], [[], [[], []], [[], []]], [[], []], []]
```

Or to insert a child in a tree:

```
sage: with tt2.clone() as tt3:
....:     tt3.insert(2, OrderedTree([]))
sage: tt3
[[], [[], [[], []], [[], []]], [], [[], []]]
```

We check that `tt1` is not modified and that everything is correct with respect to equality:

```
sage: tt1
[[], [[], []], [[], []]]
sage: tt1 == tt2
False
sage: tt1.__hash__() == tt2.__hash__()
False
```

TESTS:

```
sage: tt1bis = OrderedTree(tt1)
sage: with tt1.clone() as tt1:
....:     tt1[1] = tt1bis
sage: tt1
[[], [[], [[], []], [[], []]], [[], []]]
sage: tt1 == tt2
True
sage: tt1.__hash__() == tt2.__hash__()
True
sage: len(tt1)
3
sage: tt1[2]
[[], []]
sage: tt1[3]
Traceback (most recent call last):
...
IndexError: list index out of range
sage: tt1[1:2]
[[[], [[], []], [[], []]]]
```

Various tests involving construction, equality and hashing:

```
sage: OrderedTree() == OrderedTree()
True
sage: t1 = OrderedTree([[],[[]]])
sage: t2 = OrderedTree([[],[[]]])
sage: t1 == t2
```

```
True
sage: t2 = OrderedTree(t1)
sage: t1 == t2
True
sage: t1 = OrderedTree([[],[[]]])
sage: t2 = OrderedTree([[[]],[]])
sage: t1 == t2
False

sage: t1 = OrderedTree([[],[[]]])
sage: t2 = OrderedTree([[],[[]]])
sage: t1.__hash__() == t2.__hash__()
True
sage: t2 = OrderedTree([[[]],[]])
sage: t1.__hash__() == t2.__hash__()
False
sage: OrderedTree().__hash__() == OrderedTree([]).__hash__()
True
sage: tt1 = OrderedTree([t1,t2,t1])
sage: tt2 = OrderedTree([t1, [[[]],[]], t1])
sage: tt1.__hash__() == tt2.__hash__()
True
```

Check that the hash value is correctly updated after modification:

```
sage: with tt2.clone() as tt2:
....:     tt2[1,1] = tt1
sage: tt1.__hash__() == tt2.__hash__()
False
```

dendrog_cmp(*other*)

Return -1 if `self` is smaller than `other` in the dendrographical order; return 0 if they are equal; return 1 if `other` is smaller.

The dendrographical order is a total order on the set of unlabelled ordered rooted trees; it is defined recursively as follows: An ordered rooted tree T with children $T_1, T_2, \ldots, T_a$ is smaller than an ordered rooted tree S with children $S_1, S_2, \ldots, S_b$ if either $a < b$ or ($a = b$ and there exists a $1 \leq i \leq a$ such that $T_1 = S_1, T_2 = S_2, \ldots, T_{i-1} = S_{i-1}$ and $T_i < S_i$).

INPUT:

- `other` – an ordered rooted tree

OUTPUT:

- -1, if `smaller < other` with respect to the dendrographical order.
- 0, if `smaller == other` (as unlabelled ordered rooted trees).
- 1, if `smaller > other` with respect to the dendrographical order.

Note: It is possible to provide labelled trees to this method; however, their labels are ignored.

EXAMPLES:

```
sage: OT = OrderedTree
sage: ta = OT([])
sage: tb = OT([[], [], [[], []]])
sage: tc = OT([[], [[], []], []])
sage: td = OT([[[], []], [], []])
sage: te = OT([[], []])
```

```
sage: tf = OT([[], [], []])
sage: tg = OT([[[], []], [[], []]])
sage: l = [ta, tb, tc, td, te, tf, tg]
sage: [l[i].dendrog_cmp(l[j]) for i in range(7) for j in range(7)]
[0, -1, -1, -1, -1, -1, -1,
 1, 0, -1, -1, 1, 1, 1,
 1, 1, 0, -1, 1, 1, 1,
 1, 1, 1, 0, 1, 1, 1,
 1, -1, -1, -1, 0, -1, -1,
 1, -1, -1, -1, 1, 0, 1,
 1, -1, -1, -1, 1, -1, 0]
```

dendrog_normalize(*inplace=False*)

Return the normalized tree of the *unlabelled* ordered rooted tree `self` with respect to the dendrographical order.

INPUT:

- `inplace` – (default `False`) boolean; if `True`, then `self` is modified and nothing returned; otherwise the normalized tree is returned

The normalized tree of an unlabelled ordered rooted tree t with respect to the dendrographical order is an unlabelled ordered rooted tree defined recursively as follows: We first replace all children of t by their normalized trees (with respect to the dendrographical order); then, we reorder these children in weakly increasing order with respect to the dendrographical order (`dendrog_cmp()`).

This can be viewed as an alternative to `normalize()` for the case of unlabelled ordered rooted trees.

EXAMPLES:

```
sage: OT = OrderedTree
sage: ta = OT([[],[[]]])
sage: tb = OT([[[]],[]])
sage: ta.dendrog_normalize() == tb.dendrog_normalize()
True
sage: ta == tb
False
sage: ta.dendrog_normalize()
[[], [[]]]
```

An example with inplace normalization:

```
sage: OT = OrderedTree
sage: ta = OT([[],[[]]])
sage: tb = OT([[[]],[]])
sage: ta.dendrog_normalize(inplace=True); ta
[[], [[]]]
sage: tb.dendrog_normalize(inplace=True); tb
[[], [[]]]
```

is_empty()

Return if `self` is the empty tree.

For ordered trees, this always returns `False`.

Note: this is different from `bool(t)` which returns whether `t` has some child or not.

EXAMPLES:

```
sage: t = OrderedTrees(4)([[],[[]]])
sage: t.is_empty()
False
sage: bool(t)
True
```

left_right_symmetry()

Return the symmetric tree of `self`.

The symmetric tree $s(T)$ of an ordered tree T is defined as follows: If T is an ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of T is the ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right).

EXAMPLES:

```
sage: T = OrderedTree([[],[[]]])
sage: T.left_right_symmetry()
[[[]], []]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.left_right_symmetry()
[[[[]], []], [[], []], []]
```

normalize(*inplace=False*)

Return the normalized tree of `self`.

INPUT:

- `inplace` – boolean, (default `False`) if `True`, then `self` is modified and nothing returned. Otherwise the normalized tree is returned.

The normalization of an ordered tree t is an ordered tree s which has the property that t and s are isomorphic as *unordered* rooted trees, and that if two ordered trees t and t' are isomorphic as *unordered* rooted trees, then the normalizations of t and t' are identical. In other words, normalization is a map from the set of ordered trees to itself which picks a representative from every equivalence class with respect to the relation of "being isomorphic as unordered trees", and maps every ordered tree to the representative chosen from its class.

This map proceeds recursively by first normalizing every subtree, and then sorting the subtrees according to the value of the `sort_key()` method.

See also `dendrog_normalize()` for an alternative that works for unlabelled trees.

Consider the quotient map π that sends a planar rooted tree to the associated unordered rooted tree. Normalization is the composite $s \circ \pi$, where s is a section of π.

EXAMPLES:

```
sage: OT = OrderedTree
sage: ta = OT([[],[[]]])
sage: tb = OT([[[]],[]])
sage: ta.normalize() == tb.normalize()
True
sage: ta == tb
False
```

An example with inplace normalization:

```
sage: OT = OrderedTree
sage: ta = OT([[],[[]]])
sage: tb = OT([[[]],[]])
sage: ta.normalize(inplace=True); ta
[[], [[]]]
```

```
sage: tb.normalize(inplace=True); tb
[[], [[]]]
```

sort_key()

Return a tuple of nonnegative integers encoding the ordered tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the tree uniquely, and can be used to sort the ordered trees.

Note: By default, this method does not encode any extra structure that `self` might have – e.g., if you were to define a class `EdgeColoredOrderedTree` which implements edge-colored trees and which inherits from `OrderedTree`, then the `sort_key()` method it would inherit would forget about the colors of the edges (and thus would not characterize edge-colored trees uniquely). If you want to preserve extra data, you need to override this method or use a new method. For instance, on the `LabelledOrderedTree` subclass, this method is overridden by a slightly different method, which encodes not only the numbers of children of the nodes of `self`, but also their labels. Be careful with using overridden methods, however: If you have (say) a class `BalancedTree` which inherits from `OrderedTree` and which encodes balanced trees, and if you have another class `BalancedLabelledOrderedTree` which inherits both from `BalancedOrderedTree` and from `LabelledOrderedTree`, then (depending on the MRO) the default `sort_key()` method on `BalancedLabelledOrderedTree` (unless manually overridden) will be taken either from `BalancedTree` or from `LabelledOrderedTree`, and in the former case will ignore the labelling!

EXAMPLES:

```
sage: RT = OrderedTree
sage: RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[]]).sort_key()
(2, 1, 0, 0)
```

to_binary_tree_left_branch()

Return a binary tree of size $n-1$ (where n is the size of t, and where t is `self`) obtained from t by the following recursive rule:

- if x is the left brother of y in t, then x becomes the left child of y;
- if x is the last child of y in t, then x becomes the right child of y,

and removing the root of t.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_binary_tree_left_branch()
[[., .], .]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [., .]]]
```

TESTS:

```
sage: T = OrderedTree([[],[]])
sage: T == T.to_binary_tree_left_branch().to_ordered_tree_left_branch()
True
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
```

```
sage: T == T.to_binary_tree_left_branch().to_ordered_tree_left_branch()
True
```

to_binary_tree_right_branch()

Return a binary tree of size $n-1$ (where n is the size of t, and where t is `self`) obtained from t by the following recursive rule:

- if x is the right brother of y in t, then'x' becomes the right child of y;
- if x is the first child of y in t, then x becomes the left child of y,

and removing the root of t.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_binary_tree_right_branch()
[., [., .]]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.to_binary_tree_right_branch()
[., [[., [., .]], [[., [[., .], .]], .]]]
```

TESTS:

```
sage: T = OrderedTree([[],[]])
sage: T == T.to_binary_tree_right_branch().to_ordered_tree_right_branch()
True
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T == T.to_binary_tree_right_branch().to_ordered_tree_right_branch()
True
```

to_dyck_word()

Return the Dyck path corresponding to `self` where the maximal height of the Dyck path is the depth of `self`.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_dyck_word()
[1, 0, 1, 0]
sage: T = OrderedTree([[],[[]]])
sage: T.to_dyck_word()
[1, 0, 1, 1, 0, 0]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.to_dyck_word()
[1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
```

to_poset(*root_to_leaf=False*)

Return the poset obtained by interpreting the tree as a Hasse diagram. The default orientation is from leaves to root but you can pass `root_to_leaf=True` to obtain the inverse orientation.

INPUT:

- `root_to_leaf` – boolean, true if the poset orientation should be from root to leaves. It is false by default.

EXAMPLES:

```
sage: t = OrderedTree([])
sage: t.to_poset()
Finite poset containing 1 elements
sage: p = OrderedTree([[[]],[],[]]).to_poset()
```

```
sage: p.height(), p.width()
(3, 3)
```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:

```
sage: t = OrderedTree([[[]],[],[]]).canonical_labelling().to_poset()
sage: t.height(), t.width()
(3, 3)
```

to_undirected_graph()

Return the undirected graph obtained from the tree nodes and edges.

EXAMPLES:

```
sage: t = OrderedTree([])
sage: t.to_undirected_graph()
Graph on 1 vertex
sage: t = OrderedTree([[[]],[],[]])
sage: t.to_undirected_graph()
Graph on 5 vertices
```

If the tree is labelled, we use its labelling to label the graph. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

EXAMPLES:

```
sage: t = OrderedTree([[[]],[],[]])
sage: t.canonical_labelling().to_undirected_graph()
Graph on 5 vertices
sage: t.canonical_labelling().to_undirected_graph() == t.to_undirected_graph()
False
sage: OrderedTree([[],[]]).to_undirected_graph() == OrderedTree([[[]]]).to_undirected_graph(
True
sage: OrderedTree([[],[],[]]).to_undirected_graph() == OrderedTree([[[[]]]]).to_undirected_g
False
```

class sage.combinat.ordered_tree.**OrderedTrees**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Factory for ordered trees

INPUT:

- size – (optional) an integer

OUTPUT:

- the set of all ordered trees (of the given size if specified)

EXAMPLES:

```
sage: OrderedTrees()
Ordered trees

sage: OrderedTrees(2)
Ordered trees of size 2
```

Note: this is a factory class whose constructor returns instances of subclasses.

Note: the fact that OrderedTrees is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

---

leaf()

Return a leaf tree with `self` as parent

EXAMPLES:

```
sage: OrderedTrees().leaf()
[]
```

TEST:

```
sage: (OrderedTrees().leaf() is
....:     sage.combinat.ordered_tree.OrderedTrees_all().leaf())
True
```

class sage.combinat.ordered_tree.**OrderedTrees_all**

Bases: sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets, sage.combinat.ordered_tree.OrderedTrees

The set of all ordered trees.

EXAMPLES:

```
sage: OT = OrderedTrees(); OT
Ordered trees
sage: OT.cardinality()
+Infinity
```

Element

alias of OrderedTree

labelled_trees()

Return the set of labelled trees associated to `self`

EXAMPLES:

```
sage: OrderedTrees().labelled_trees()
Labelled ordered trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`

EXAMPLES:

```
sage: OrderedTrees().unlabelled_trees()
Ordered trees
```

class sage.combinat.ordered_tree.**OrderedTrees_size**(*size*)

Bases: sage.combinat.ordered_tree.OrderedTrees

The enumerated sets of binary trees of a given size

EXAMPLES:

```
sage: S = OrderedTrees(3); S
Ordered trees of size 3
sage: S.cardinality()
2
sage: S.list()
[[[], []], [[[]]]]
```

cardinality()
The cardinality of `self`

This is a Catalan number.

TESTS:

```
sage: OrderedTrees(0).cardinality()
0
sage: OrderedTrees(1).cardinality()
1
sage: OrderedTrees(6).cardinality()
42
```

element_class()
The class of the element of `self`

EXAMPLES:

```
sage: from sage.combinat.ordered_tree import OrderedTrees_size, OrderedTrees_all
sage: S = OrderedTrees_size(3)
sage: S.element_class is OrderedTrees().element_class
True
sage: S.first().__class__ == OrderedTrees_all().first().__class__
True
```

random_element()
Return a random `OrderedTree` with uniform probability.

This method generates a random `DyckWord` and then uses a bijection between Dyck words and ordered trees.

EXAMPLES:

```
sage: OrderedTrees(5).random_element() # random
[[[], []], []]
sage: OrderedTrees(0).random_element()
Traceback (most recent call last):
...
EmptySetError: There are no ordered trees of size 0
sage: OrderedTrees(1).random_element()
[]
```

TESTS:

```
sage: all([OrderedTrees(10).random_element() in OrderedTrees(10) for i in range(20)])
True
```

5.1.140 Output functions

These are the output functions for latexing partitions and tableaux.

AUTHORS:

- Mike Hansen (?): initial version
- Andrew Mathas (2013-02-14): Added support for displaying conventions and lines, and tableaux of skew partition, composition, and skew/composition/partition/tableaux tuple shape.

`sage.combinat.output.`**tex_from_array**(*array*, *with_lines=True*)
Return a latex string for a two dimensional array of partition, composition or skew composition shape

INPUT:

- `array` – a list of list
- **`with_lines` – a boolean (default: `True`)** Whether to draw a line to separate the entries in the array.

Empty rows are allowed; however, such rows should be given as `[None]` rather than `[]`.

The array is drawn using either the English or French convention following `Tableaux.global_options`().

See also:

`tex_from_array_tuple()`

EXAMPLES:

```
sage: from sage.combinat.output import tex_from_array
sage: print tex_from_array([[1,2,3],[4,5]])
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[b]{*{3}c}\cline{1-3}
\lr{1}&\lr{2}&\lr{3}\\\cline{1-3}
\lr{4}&\lr{5}\\\cline{1-2}
\end{array}$}
}
sage: print tex_from_array([[1,2,3],[4,5]], with_lines=False)
{\def\lr#1{\multicolumn{1}{@{\hspace{.6ex}}c@{\hspace{.6ex}}}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[b]{*{3}c}\\
\lr{1}&\lr{2}&\lr{3}\\
\lr{4}&\lr{5}\\
\end{array}$}
}
sage: print tex_from_array([[1,2,3],[4,5,6,7],[8]])
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[b]{*{4}c}\cline{1-3}
\lr{1}&\lr{2}&\lr{3}\\\cline{1-4}
\lr{4}&\lr{5}&\lr{6}&\lr{7}\\\cline{1-4}
\lr{8}\\\cline{1-1}
\end{array}$}
}
sage: print tex_from_array([[1,2,3],[4,5,6,7],[8]], with_lines=False)
{\def\lr#1{\multicolumn{1}{@{\hspace{.6ex}}c@{\hspace{.6ex}}}{\raisebox{-.3ex}{$#1$}}}

\raisebox{-.6ex}{$\begin{array}[t]{*{4}c}\\
&\lr{8}\\
&\lr{5}&\lr{6}&\lr{7}\\
&&\lr{3}\\
\end{array}$}
}
sage: Tableaux.global_options.reset()
```

sage.combinat.output.**tex_from_array_tuple**(*a_tuple*, *with_lines=True*)

Return a latex string for a tuple of two dimensional array of partition, composition or skew composition shape.

INPUT:

- `a_tuple` – a tuple of lists of lists
- `with_lines` – a boolean (default: `True`) Whether to draw lines to separate the entries in the components of `a_tuple`.

See also:

`tex_from_array()` for the description of each array

EXAMPLES:

```
sage: from sage.combinat.output import tex_from_array_tuple
sage: print tex_from_array_tuple([[[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]])
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[b]{*{3}c}\cline{1-3}
\lr{1}&\lr{2}&\lr{3}\\\cline{1-3}
\lr{4}&\lr{5}\\\cline{1-2}
\end{array}$},\emptyset,\raisebox{-.6ex}{$\begin{array}[b]{*{3}c}\cline{2-3}
&\lr{6}&\lr{7}\\\cline{2-3}
&\lr{8}\\\cline{1-2}
\lr{9}\\\cline{1-1}
\end{array}$}
}
sage: print tex_from_array_tuple([[[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]], with_lines=Fals
{\def\lr#1{\multicolumn{1}{@{\hspace{.6ex}}c@{\hspace{.6ex}}}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[b]{*{3}c}\\
\lr{1}&\lr{2}&\lr{3}\\
\lr{4}&\lr{5}\\
\end{array}$},\emptyset,\raisebox{-.6ex}{$\begin{array}[b]{*{3}c}\\
&\lr{6}&\lr{7}\\
```

```
&\lr{8}\\
\lr{9}\\
\end{array}$}
}
sage: Tableaux.global_options(convention="french")
sage: print tex_from_array_tuple([[[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]])
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[t]{*{3}c}\cline{1-2}
\lr{4}&\lr{5}\\\cline{1-3}
\lr{1}&\lr{2}&\lr{3}\\\cline{1-3}
\end{array}$},\emptyset,\raisebox{-.6ex}{$\begin{array}[t]{*{3}c}\cline{1-1}
\lr{9}\\\cline{1-2}
&\lr{8}\\\cline{2-3}
&\lr{6}&\lr{7}\\\cline{2-3}
\end{array}$}
}
sage: print tex_from_array_tuple([[[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]], with_lines=Fals
{\def\lr#1{\multicolumn{1}{@{\hspace{.6ex}}c@{\hspace{.6ex}}}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[t]{*{3}c}\\
\lr{4}&\lr{5}\\
\lr{1}&\lr{2}&\lr{3}\\
\end{array}$},\emptyset,\raisebox{-.6ex}{$\begin{array}[t]{*{3}c}\\
\lr{9}\\
&\lr{8}\\
&\lr{6}&\lr{7}\\
\end{array}$}
}
```

sage.combinat.output.**tex_from_skew_array**(*array*, *with_lines=False*, *align='b'*)

This function creates latex code for a "skew composition" `array`. That is, for a two dimensional array in which each row can begin with an arbitrary number `None`'s and the remaining entries could, in principe, be anything but probably should be strings or integers of similar width. A row consisting completely of `None`'s is allowed.

INPUT:

- `array` – The array
- `with_lines` – (Default: `False`) If `True` lines are drawn, if `False` they are not
- `align` – (Default: `'b'`) Determines the alignment on the latex array environments

EXAMPLES:

```
sage: array=[[None, 2,3,4],[None,None],[5,6,7,8]]
sage: print sage.combinat.output.tex_from_skew_array(array)
\raisebox{-.6ex}{$\begin{array}[b]{*{4}c}\\
&\lr{2}&\lr{3}&\lr{4}\\
&\\
\lr{5}&\lr{6}&\lr{7}&\lr{8}\\
\end{array}$}
```

5.1.141 Parking Functions

INFORMALLY (reference [Beck]):

Imagine a one-way cul-de-sac with n parking spots. We will give the first parking spot the number 1, the next one number 2, etc., down to the last one, number n. Initially they are all free, but there are n cars approaching the street, and they would all like to park there. To make life interesting, every car has a parking preference, and we record the

preferences in a sequence; For example, if $n = 3$, the sequence $(2, 1, 1)$ means that the first car would like to park at spot number 2, the second car prefers parking spot number 1, and the last car would also like to part at number 1. The street is very narrow, so there is no way to back up. Now each car enters the street and approaches its preferred parking spot; if it is free, it parks there, and if not, it moves down the street to the first available spot. We call a sequence a parking function (of length n) if all cars end up finding a parking spot. For example, the sequence $(2, 1, 1)$ is a parking sequence (of length 3), whereas the sequence $(2, 3, 2)$ is not.

FORMALLY:

A parking function of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck path of size n such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

`sage.combinat.parking_functions.`**`ParkingFunction`**(*pf=None*, *labelling=None*, *area_sequence=None*, *labelled_dyck_word=None*)

Return the combinatorial class of Parking Functions.

A *parking function* of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A *parking function* of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck Path of size n such that $D[i] \geq 0$, $D[i+1] \leq D[i]+1$ and if $D[i+1] = D[i]+1$ then $L[i+1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

INPUT:

- `pf` – (default: None) a list whose increasing rearrangement satisfies $b_i \leq i$
- `labelling` – (default: None) a labelling of the Dyck path
- `area_sequence` – (default: None) an area sequence of a Dyck path
- `labelled_dyck_word` – (default: None) a Dyck word with 1's replaced by labelling

OUTPUT:

- A parking function

EXAMPLES:

```
sage: ParkingFunction([])
[]
sage: ParkingFunction([1])
[1]
sage: ParkingFunction([2])
Traceback (most recent call last):
...
```

```
ValueError: [2] is not a parking function.
sage: ParkingFunction([1,2])

```

class sage.combinat.parking_functions.**ParkingFunction_class**(*lst*)

Bases: sage.combinat.combinat.CombinatorialObject

TESTS:

```
sage: ParkingFunction([1, 1, 2, 2, 5, 6])
[1, 1, 2, 2, 5, 6]
```

area()

Return the area of the labelled Dyck path corresponding to the parking function.

INPUT:

- self – parking function word

OUTPUT:

- the sum of squares under and over the main diagonal the Dyck Path, corresponding to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.area()
6

sage: ParkingFunction([3,1,1,4]).area()
1
sage: ParkingFunction([4,1,1,1]).area()
3
sage: ParkingFunction([2,1,4,1]).area()
2
```

cars_permutation()

Return the sequence of cars that take parking spots 1 through n and corresponding to the parking function.

For example, cars_permutation(PF) = [2, 4, 5, 6, 3, 1, 7] means that car 2 takes spots 1, car 4 takes spot 2, ..., car 1 takes spot 6 and car 7 takes spot 7.

INPUT:

- self – parking function word

OUTPUT:

- the permutation of cars corresponding to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.cars_permutation()
[2, 4, 5, 6, 3, 1, 7]

sage: ParkingFunction([3,1,1,4]).cars_permutation()
[2, 3, 1, 4]
sage: ParkingFunction([4,1,1,1]).cars_permutation()
[2, 3, 4, 1]
sage: ParkingFunction([2,1,4,1]).cars_permutation()
[2, 1, 4, 3]
```

characteristic_quasisymmetric_function(*q=None*, *R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field*)

Return the characteristic quasisymmetric function of `self`.

The characteristic function of the Parking Function is the sum over all permutation labellings of the Dyck path $q^{dinv(PF)}F_{ides(PF)}$ where $ides(PF)$ (`ides_composition()`) is the descent composition of diagonal reading word of the parking function.

INPUT:

- `q` – (default: `q = R('q')`) a parameter for the generating function power
- `R` – (default: `R = QQ['q','t'].fraction_field()`) the base ring to do the calculations over

OUTPUT:

- an element of the quasisymmetric functions over the ring `R`

EXAMPLES:

```
sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: cqf = sum(t**PF.area()*PF.characteristic_quasisymmetric_function() for PF in ParkingFu
(q^3+q^2*t+q*t^2+t^3+q*t)*F[1, 1, 1] + (q^2+q*t+t^2+q+t)*F[1, 2] + (q^2+q*t+t^2+q+t)*F[2, 1]
sage: s = SymmetricFunctions(R).s()
sage: s(cqf.to_symmetric_function())
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: s(cqf.to_symmetric_function()).nabla(power = -1)
s[1, 1, 1]

sage: p = ParkingFunction([3, 1, 2])
sage: p.characteristic_quasisymmetric_function()
q*F[2, 1]
sage: pf = ParkingFunction([1,2,7,2,1,2,3,2,1])
sage: pf.characteristic_quasisymmetric_function()
q^2*F[1, 1, 1, 2, 1, 3]
```

diagonal_composition()

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, `touch_composition(PF) = [4, 3]` means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

INPUT:

- self – parking function word

OUTPUT:

- the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]

sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]
```

diagonal_reading_word()

Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

INPUT:

- self – parking function word

OUTPUT:

- returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]

sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()
[2, 4, 3, 1]

sage: ParkingFunction([1, 1, 1]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 4, 3, 1]).diagonal_word()
[4, 2, 3, 1]
```

diagonal_word()

Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

INPUT:

- self – parking function word

OUTPUT:

- returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]

sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()
[2, 4, 3, 1]

sage: ParkingFunction([1, 1, 1]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 4, 3, 1]).diagonal_word()
[4, 2, 3, 1]
```

dinv()

Return the number of inversions of a labelled Dyck path corresponding to the parking function (see [Hag08] p. 74).

Same as the cardinality of `dinversion_pairs()`.

INPUT:

- `self` – parking function word

OUTPUT:

- the number of dinversion pairs

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinv()
6

sage: ParkingFunction([3,1,1,4]).dinv()
3
sage: ParkingFunction([4,1,1,1]).dinv()
1
sage: ParkingFunction([2,1,4,1]).dinv()
2
```

dinversion_pairs()

Return the descent inversion pairs of a labelled Dyck path corresponding to the parking function.

INPUT:

- `self` – parking function word

OUTPUT:

- the primary and secondary diversion pairs

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]
```

```
sage: ParkingFunction([3,1,1,4]).dinversion_pairs()
[(0, 3), (2, 3), (1, 2)]
sage: ParkingFunction([4,1,1,1]).dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).dinversion_pairs()
[(0, 3), (1, 3)]
```

ides()

Return the descents() sequence of the inverse of the diagonal_reading_word() of self.

For example, ides(PF) = [1, 2, 3, 5] means that descents are at the 2nd, 3rd, 4th and 6th positions in the inverse of the diagonal_reading_word() of the parking function (see [GXZ] p. 2).

INPUT:

- self – parking function word

OUTPUT:

- the descents sequence of the inverse of the diagonal_reading_word() of the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides()
[1, 2, 3, 5]

sage: ParkingFunction([3,1,1,4]).ides()
[1]
sage: ParkingFunction([4,1,1,1]).ides()
[1, 2]
sage: ParkingFunction([4,3,1,1]).ides()
[2]
```

ides_composition()

Return the descents_composition() of the inverse of the diagonal_reading_word() of corresponding parking function.

For example, ides_composition(PF) = [4, 2, 1] means that the descents of the inverse of the permutation diagonal_reading_word() of the parking function with word PF are at the 4th and 6th positions.

INPUT:

- self – parking function word

OUTPUT:

- the descents composition of the inverse of the diagonal_reading_word() of the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides_composition()
[2, 1, 1, 2, 1]

sage: ParkingFunction([3,1,1,4]).ides_composition()
[2, 2]
sage: ParkingFunction([4,1,1,1]).ides_composition()
[2, 1, 1]
sage: ParkingFunction([4,3,1,1]).ides_composition()
[3, 1]
```

jump()

Return the sum of the differences between the parked and preferred parking spots.

See [Shin] p. 18.

INPUT:

- `self` – a parking function word

OUTPUT:

- the sum of the differences between the parked and preferred parking spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump()
6

sage: ParkingFunction([3,1,1,4]).jump()
1
sage: ParkingFunction([4,1,1,1]).jump()
3
sage: ParkingFunction([2,1,4,1]).jump()
2
```

jump_list()

Return the displacements of cars that corresponds to the parking function.

For example, `jump_list(PF) = [0, 0, 0, 0, 1, 3, 2]` means that car 1 through 4 parked in their preferred spots, car 5 had to park one spot farther (jumped or was displaced by one spot), car 6 had to jump 3 spots, and car 7 had to jump two spots.

INPUT:

- `self` – parking function word

OUTPUT:

- the displacements sequence of parked cars which corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump_list()
[0, 0, 0, 0, 1, 3, 2]

sage: ParkingFunction([3,1,1,4]).jump_list()
[0, 0, 1, 0]
sage: ParkingFunction([4,1,1,1]).jump_list()
[0, 0, 1, 2]
sage: ParkingFunction([2,1,4,1]).jump_list()
[0, 0, 0, 2]
```

luck()

Return the number of cars that parked in their preferred parking spots (see [Shin] p. 33).

INPUT:

- `self` – parking function word

OUTPUT:

•the number of cars that parked in their preferred parking spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.luck()
4

sage: ParkingFunction([3,1,1,4]).luck()
3
sage: ParkingFunction([4,1,1,1]).luck()
2
sage: ParkingFunction([2,1,4,1]).luck()
3
```

lucky_cars()

Return the cars that can park in their preferred spots. For example, `lucky_cars(PF) = [1, 2, 7]` means that cars 1, 2 and 7 parked in their preferred spots and all the other cars did not.

INPUT:

•`self` – parking function word

OUTPUT:

•the cars that can park in their preferred spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.lucky_cars()
[1, 2, 3, 4]

sage: ParkingFunction([3,1,1,4]).lucky_cars()
[1, 2, 4]
sage: ParkingFunction([4,1,1,1]).lucky_cars()
[1, 2]
sage: ParkingFunction([2,1,4,1]).lucky_cars()
[1, 2, 3]
```

parking_permutation()

Return the sequence of parking spots that are taken by cars 1 through n and corresponding to the parking function.

For example, `parking_permutation(PF) = [6, 1, 5, 2, 3, 4, 7]` means that spot 6 is taken by car 1, spot 1 by car 2, spot 5 by car 3, spot 2 is taken by car 4, spot 3 is taken by car 5, spot 4 is taken by car 6 and spot 7 is taken by car 7.

INPUT:

•`self` – parking function word

OUTPUT:

•the permutation of parking spots that corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]
```

```
sage: ParkingFunction([3,1,1,4]).parking_permutation()
[3, 1, 2, 4]
sage: ParkingFunction([4,1,1,1]).parking_permutation()
[4, 1, 2, 3]
sage: ParkingFunction([2,1,4,1]).parking_permutation()
[2, 1, 4, 3]
```

pretty_print (*underpath=True*)

Displays a parking function as a lattice path consisting of a Dyck path and a labelling with the labels displayed along the edges of the Dyck path.

INPUT:

- `underpath` – if the length of the parking function is less than or equal to 9 then display the labels under the path if `underpath` is True otherwise display them to the right of the path (default: `True`)

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print()
          ___
         _|1x
        |7x  .
   _____|3 . .
  |5x x  . . .
 _|4x  . . . .
|6x  . . . . .
|2 . . . . . .

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print(underpath = false)
          ___
         _| x  1
        | x  . 7
   _____|  . . 3
  | x x  . . . 5
 _| x  . . . . 4
| x  . . . . . 6
|  . . . . . . 2

sage: ParkingFunction([3, 1, 1, 4]).pretty_print()
       _
     _|4
 ___|1 .
|3x  . .
|2 . . .

sage: ParkingFunction([1,1,1]).pretty_print()
 _____
|3x x
|2x  .
|1 . .

sage: ParkingFunction([4,1,1,1]).pretty_print()
       _
 _____|1
|4x x  .
|3x  . .
|2 . . .
```

```
sage: ParkingFunction([2,1,4,1]).pretty_print()
       _
   ___|3
 _|1x  .
|4x  . .
|2 . . .

sage: ParkingFunction([2,1,4,1]).pretty_print(underpath = false)
       _
   ___|  3
 _| x  . 1
| x  . . 4
|  . . . 2

sage: pf = ParkingFunction([1,2,3,7,3,2,1,2,3,2,1])
sage: pf.pretty_print()
              _________
     ________| x x x x   4
    | x x x x x x x x  .  9
    | x x x x x x x  . .  5
   _| x x x x x  . . .  3
  | x x x x x  . . . . 10
  | x x x x  . . . . .  8
  | x x x  . . . . . .  6
 _| x x  . . . . . . .  2
| x x  . . . . . . . . 11
| x  . . . . . . . . .  7
|  . . . . . . . . . .  1
```

primary_dinversion_pairs()

Return the primary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

INPUT:

- self – parking function word

OUTPUT:

- the pairs (i, j) such that $i < j$, and i^{th} area = j^{th} area, and i^{th} label < j^{th} label

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]

sage: ParkingFunction([3,1,1,4]).primary_dinversion_pairs()
[(0, 3), (2, 3)]
sage: ParkingFunction([4,1,1,1]).primary_dinversion_pairs()
[]
sage: ParkingFunction([2,1,4,1]).primary_dinversion_pairs()
[(0, 3)]
```

secondary_dinversion_pairs()

Return the secondary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

INPUT:

- self – parking function word

OUTPUT:

•the pairs (i, j) such that $i < j$, and i^{th} area = j^{th} area +1, and i^{th} label > j^{th} label

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.secondary_dinversion_pairs()
[(1, 4), (2, 4), (3, 6)]

sage: ParkingFunction([3,1,1,4]).secondary_dinversion_pairs()
[(1, 2)]
sage: ParkingFunction([4,1,1,1]).secondary_dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).secondary_dinversion_pairs()
[(1, 3)]
```

to_NonDecreasingParkingFunction()

Return the non-decreasing parking function which underlies the parking function.

INPUT:

•`self` – parking function word

OUTPUT:

•a sorted parking function

See also:

`NonDecreasingParkingFunction()`

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]

sage: ParkingFunction([3,1,1,4]).to_NonDecreasingParkingFunction()
[1, 1, 3, 4]
sage: ParkingFunction([4,1,1,1]).to_NonDecreasingParkingFunction()
[1, 1, 1, 4]
sage: ParkingFunction([2,1,4,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
sage: ParkingFunction([4,1,2,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

to_area_sequence()

Return the area sequence of the support Dyck path of the parking function.

INPUT:

•`self` – parking function word

OUTPUT:

•the area sequence of the Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_area_sequence()
[0, 1, 1, 2, 0, 1, 1]
```

```
sage: ParkingFunction([3,1,1,4]).to_area_sequence()
[0, 1, 0, 0]
sage: ParkingFunction([4,1,1,1]).to_area_sequence()
[0, 1, 2, 0]
sage: ParkingFunction([2,1,4,1]).to_area_sequence()
[0, 1, 1, 0]
```

to_dyck_word()

Return the support Dyck word of the parking function.

INPUT:

- self – parking function word

OUTPUT:

- the Dyck word of the corresponding parking function

See also:

DyckWord()

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0]

sage: ParkingFunction([3,1,1,4]).to_dyck_word()
[1, 1, 0, 0, 1, 0, 1, 0]
sage: ParkingFunction([4,1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0, 1, 0]
sage: ParkingFunction([2,1,4,1]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]
```

to_labelled_dyck_word()

Return the labelled Dyck word corresponding to the parking function.

This is a representation of the parking function as a list where the entries of 1 in the Dyck word are replaced with the corresponding label.

INPUT:

- self – parking function word

OUTPUT:

- the labelled Dyck word of the corresponding parking function which is twice the size of parking function word

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]

sage: ParkingFunction([3,1,1,4]).to_labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]
sage: ParkingFunction([4,1,1,1]).to_labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]
sage: ParkingFunction([2,1,4,1]).to_labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]
```

to_labelling_area_sequence_pair()

Return a pair consisting of a labelling and an area sequence of a Dyck path which corresponds to the given parking function.

INPUT:

- `self` – the parking function word

OUTPUT:

- returns a pair `(L, D)` where `L` is a labelling and `D` is the area sequence of the underlying Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])

sage: ParkingFunction([1, 1, 1]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 2])
sage: ParkingFunction([1, 2, 3]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 0, 0])
sage: ParkingFunction([1, 1, 2]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 1])
sage: ParkingFunction([1, 1, 3, 1]).to_labelling_area_sequence_pair()
([1, 2, 4, 3], [0, 1, 2, 1])
```

to_labelling_dyck_word_pair()

Return the pair `(L, D)` where `L` is a labelling and `D` is the Dyck word of the parking function.

INPUT:

- `self` – parking function word

OUTPUT:

- the pair `(L, D)`, where `L` is the labelling and `D` is the Dyck word of the parking function

See also:

`DyckWord()`

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_dyck_word_pair()
([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0])

sage: ParkingFunction([3,1,1,4]).to_labelling_dyck_word_pair()
([2, 3, 1, 4], [1, 1, 0, 0, 1, 0, 1, 0])
sage: ParkingFunction([4,1,1,1]).to_labelling_dyck_word_pair()
([2, 3, 4, 1], [1, 1, 1, 0, 0, 0, 1, 0])
sage: ParkingFunction([2,1,4,1]).to_labelling_dyck_word_pair()
([2, 4, 1, 3], [1, 1, 0, 1, 0, 0, 1, 0])
```

to_labelling_permutation()

Return the labelling of the support Dyck path of the parking function.

INPUT:

- `self` – parking function word

OUTPUT:

- the labelling of the Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_permutation()
[2, 6, 4, 5, 3, 7, 1]

sage: ParkingFunction([3,1,1,4]).to_labelling_permutation()
[2, 3, 1, 4]
sage: ParkingFunction([4,1,1,1]).to_labelling_permutation()
[2, 3, 4, 1]
sage: ParkingFunction([2,1,4,1]).to_labelling_permutation()
[2, 4, 1, 3]
```

touch_composition()

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, `touch_composition(PF) = [4, 3]` means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

INPUT:

- `self` – parking function word

OUTPUT:

- the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]

sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]
```

touch_points()

Return the sequence of touch points which corresponds to the labelled Dyck path after initial step.

For example, `touch_points(PF) = [4, 7]` means that after the initial step, the path touches the main diagonal at points $(4, 4)$ and $(7, 7)$.

INPUT:

- `self` – parking function word

OUTPUT:

- the sequence of touch points after the initial step of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_points()
[4, 7]

sage: ParkingFunction([3,1,1,4]).touch_points()
[2, 3, 4]
```

```
sage: ParkingFunction([4,1,1,1]).touch_points()
[3, 4]
sage: ParkingFunction([2,1,4,1]).touch_points()
[3, 4]
```

sage.combinat.parking_functions.**ParkingFunctions**(*n=None*)

Return the combinatorial class of Parking Functions.

A *parking function* of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A *parking function* of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck Path of size n such that $D[i] \geq 0$, $D[i+1] \leq D[i]+1$ and if $D[i+1] = D[i]+1$ then $L[i+1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

EXAMPLES:

Here are all parking functions of size 3:

```
sage: from sage.combinat.parking_functions import ParkingFunctions
sage: ParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1], [3, 1, 1],
 [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1],
 [3, 1, 2], [3, 2, 1]]
```

If no size is specified, then ParkingFunctions returns the combinatorial class of all parking functions.

```
sage: PF = ParkingFunctions(); PF
Parking functions
sage: [] in PF
True
sage: [1] in PF
True
sage: [2] in PF
False
sage: [1,3,1] in PF
True
sage: [1,4,1] in PF
False
```

If the size n is specified, then ParkingFunctions returns the combinatorial class of all parking functions of size n.

```
sage: PF = ParkingFunctions(0)
sage: PF.list()
[[]]
sage: PF = ParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
 [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
 [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: PF3 = ParkingFunctions(3); PF3
Parking functions of size 3
sage: [] in PF3
```

```
False
sage: [1] in PF3
False
sage: [1,3,1] in PF3
True
sage: [1,4,1] in PF3
False
```

TESTS:

```
sage: PF = ParkingFunctions(5)
sage: len(PF.list()) == PF.cardinality()
True
```

class sage.combinat.parking_functions.**ParkingFunctions_all**

Bases: sage.combinat.combinat.InfiniteAbstractCombinatorialClass

TESTS:

```
sage: from sage.combinat.parking_functions import ParkingFunctions
sage: DW = ParkingFunctions()
sage: DW == loads(dumps(DW))
True
```

class sage.combinat.parking_functions.**ParkingFunctions_n**(*n*)

Bases: sage.combinat.combinat.CombinatorialClass

The combinatorial class of parking functions of size n.

A *parking function* of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A *parking function* of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck Path of size n such that $D[i] \geq 0$, $D[i+1] \leq D[i]+1$ and if $D[i+1] = D[i]+1$ then $L[i+1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

EXAMPLES:

```
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
[1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]
```

Warning: The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

cardinality()

Return the number of parking functions of size n.

The cardinality is equal to $(n+1)^{n-1}$.

EXAMPLES:

```
sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]
```

random_element()

Return a random parking function of size n.

The algorithm uses a circular parking space with $n+1$ spots. Then all n cars can park and there remains one empty spot. Spots are then renumbered so that the empty spot is 0.

The probability distribution is uniform on the set of $(n+1)^{n-1}$ parking functions of size n.

EXAMPLES:

```
sage: pf = ParkingFunctions(8)
sage: a = pf.random_element(); a  # random
[5, 7, 2, 4, 2, 5, 1, 3]
sage: a in pf
True
```

sage.combinat.parking_functions.**from_labelled_dyck_word**(*LDW*)

Return the parking function corresponding to the labelled Dyck word.

INPUT:

- LDW – labelled Dyck word

OUTPUT:

- the parking function corresponding to the labelled Dyck word that is half the size of LDW

EXAMPLES:

```
sage: from sage.combinat.parking_functions import from_labelled_dyck_word
sage: LDW = [2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]
sage: from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]

sage: from_labelled_dyck_word([2, 3, 0, 0, 1, 0, 4, 0])
[3, 1, 1, 4]
sage: from_labelled_dyck_word([2, 3, 4, 0, 0, 0, 1, 0])
[4, 1, 1, 1]
sage: from_labelled_dyck_word([2, 4, 0, 1, 0, 0, 3, 0])
[2, 1, 4, 1]
```

sage.combinat.parking_functions.**from_labelling_and_area_sequence**(*L*, *D*)

Return the parking function corresponding to the labelling area sequence pair.

INPUT:

- L – a labelling permutation
- D – an area sequence for a Dyck word

OUTPUT:

- the parking function corresponding the labelling permutation L and D an area sequence of the corresponding Dyck path

EXAMPLES:

```
sage: from sage.combinat.parking_functions import from_labelling_and_area_sequence
sage: from_labelling_and_area_sequence([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
[6, 1, 5, 2, 2, 1, 5]
```

```
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 2])
[1, 1, 1]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 0, 0])
[1, 2, 3]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 1])
[1, 1, 2]
sage: from_labelling_and_area_sequence([1, 2, 4, 3], [0, 1, 2, 1])
[1, 1, 3, 1]
```

sage.combinat.parking_functions.**is_a**(*x*, *n=None*)

Check whether a list is a parking function.

If a size n is specified, checks if a list is a parking function of size n.

TESTS:

```
sage: from sage.combinat.parking_functions import is_a
sage: is_a([1,1,2])
True
sage: is_a([1,2,1])
True
sage: is_a([1,1,4])
False
sage: is_a([3,1,1], 3)
True
```

5.1.142 Integer partitions

A partition p of a nonnegative integer n is a non-increasing list of positive integers (the *parts* of the partition) with total sum n.

A partition can be depicted by a diagram made of rows of cells, where the number of cells in the i^{th} row starting from the top is the i^{th} part of the partition.

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition $[5, 3, 1]$ are $[[0, 4], [1, 2], [2, 0]]$.

For display options, see `Partitions.global_options`.

Note:

- Boxes is a synonym for cells. All methods will use 'cell' and 'cells' instead of 'box' and 'boxes'.
- Partitions are 0 based with coordinates in the form of (row-index, column-index).
- If given coordinates of the form `(r, c)`, then use Python's *-operator.
- Throughout this documentation, for a partition λ we will denote its conjugate partition by λ'. For more on conjugate partitions, see `Partition.conjugate()`.
- The comparisons on partitions use lexicographic order.

Note: We use the convention that lexicographic ordering is read from left-to-right. That is to say $[1, 3, 7]$ is smaller than $[2, 3, 4]$.

AUTHORS:

- Mike Hansen (2007): initial version

- Dan Drake (2009-03-28): deprecate RestrictedPartitions and implement Partitions_parts_in
- Travis Scrimshaw (2012-01-12): Implemented latex function to Partition_class
- Travis Scrimshaw (2012-05-09): Fixed Partitions(-1).list() infinite recursion loop by saying Partitions_n is the empty set.
- Travis Scrimshaw (2012-05-11): Fixed bug in inner where if the length was longer than the length of the inner partition, it would include 0's.
- Andrew Mathas (2012-06-01): Removed depreciated functions and added compatibility with the PartitionTuple classes. See trac ticket #13072
- Travis Scrimshaw (2012-10-12): Added global options. Made `Partition_class` to the element `Partition`. `Partitions*` are now all in the category framework except `PartitionsRestricted` (which will eventually be removed). Cleaned up documentation.

EXAMPLES:

There are 5 partitions of the integer 4:

```
sage: Partitions(4).cardinality()
5
sage: Partitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

We can use the method `.first()` to get the 'first' partition of a number:

```
sage: Partitions(4).first()
[4]
```

Using the method `.next()`, we can calculate the 'next' partition. When we are at the last partition, `None` will be returned:

```
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

We can use `iter` to get an object which iterates over the partitions one by one to save memory. Note that when we do something like `for part in Partitions(4)` this iterator is used in the background:

```
sage: g = iter(Partitions(4))
sage: next(g)
[4]
sage: next(g)
[3, 1]
sage: next(g)
[2, 2]
sage: for p in Partitions(4): print p
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
```

We can add constraints to the type of partitions we want. For example, to get all of the partitions of 4 of length 2, we'd do the following:

```
sage: Partitions(4, length=2).list()
[[3, 1], [2, 2]]
```

Here is the list of partitions of length at least 2 and the list of ones with length at most 2:

```
sage: Partitions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: Partitions(4, max_length=2).list()
[[4], [3, 1], [2, 2]]
```

The options `min_part` and `max_part` can be used to set constraints on the sizes of all parts. Using `max_part`, we can select partitions having only 'small' entries. The following is the list of the partitions of 4 with parts at most 2:

```
sage: Partitions(4, max_part=2).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The `min_part` options is complementary to `max_part` and selects partitions having only 'large' parts. Here is the list of all partitions of 4 with each part at least 2:

```
sage: Partitions(4, min_part=2).list()
[[4], [2, 2]]
```

The options `inner` and `outer` can be used to set part-by-part constraints. This is the list of partitions of 4 with `[3, 1, 1]` as an outer bound (that is, partitions of 4 contained in the partition `[3, 1, 1]`):

```
sage: Partitions(4, outer=[3,1,1]).list()
[[3, 1], [2, 1, 1]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear constraints on specific parts. Here is the list of the partitions of 4 of length at most 3 such that the second and third part are 1 when they exist:

```
sage: Partitions(4, outer=[oo,1,1]).list()
[[4], [3, 1], [2, 1, 1]]
```

Finally, here are the partitions of 4 with `[1,1,1]` as an inner bound (i. e., the partitions of 4 containing the partition `[1,1,1]`). Note that `inner` sets `min_length` to the length of its argument:

```
sage: Partitions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is on the difference `p[i+1]-p[i]` of two consecutive parts. Here is the list of the strictly decreasing partitions of 4:

```
sage: Partitions(4, max_slope=-1).list()
[[4], [3, 1]]
```

The constraints can be combined together in all reasonable ways. Here are all the partitions of 11 of length between 2 and 4 such that the difference between two consecutive parts is between -3 and -1:

```
sage: Partitions(11,min_slope=-3,max_slope=-1,min_length=2,max_length=4).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
```

Partition objects can also be created individually with `Partition`:

```
sage: Partition([2,1])
[2, 1]
```

Once we have a partition object, then there are a variety of methods that we can use. For example, we can get the conjugate of a partition. Geometrically, the conjugate of a partition is the reflection of that partition through its main diagonal. Of course, this operation is an involution:

```
sage: Partition([4,1]).conjugate()
[2, 1, 1, 1]
sage: Partition([4,1]).conjugate().conjugate()
[4, 1]
```

If we create a partition with extra zeros at the end, they will be dropped:

```
sage: Partition([4,1,0,0])
[4, 1]
sage: Partition([0])
[]
sage: Partition([0,0])
[]
```

The idea of a partition being followed by infinitely many parts of size 0 is consistent with the `get_part` method:

```
sage: p = Partition([5, 2])
sage: p.get_part(0)
5
sage: p.get_part(10)
0
```

We can go back and forth between the standard and the exponential notations of a partition. The exponential notation can be padded with extra zeros:

```
sage: Partition([6,4,4,2,1]).to_exp()
[1, 1, 0, 2, 0, 1]
sage: Partition(exp=[1,1,0,2,0,1])
[6, 4, 4, 2, 1]
sage: Partition([6,4,4,2,1]).to_exp(5)
[1, 1, 0, 2, 0, 1]
sage: Partition([6,4,4,2,1]).to_exp(7)
[1, 1, 0, 2, 0, 1, 0]
sage: Partition([6,4,4,2,1]).to_exp(10)
[1, 1, 0, 2, 0, 1, 0, 0, 0, 0]
```

We can get the (zero-based!) coordinates of the corners of a partition:

```
sage: Partition([4,3,1]).corners()
[(0, 3), (1, 2), (2, 0)]
```

We can compute the core and quotient of a partition and build the partition back up from them:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([2], [1], [2, 2, 2])
sage: p = Partition([11,5,5,3,2,2,2])
sage: p.core(3)
[]
sage: p.quotient(3)
([2, 1], [4], [1, 1, 1])
sage: Partition(core=[],quotient=([2, 1], [4], [1, 1, 1]))
[11, 5, 5, 3, 2, 2, 2]
```

We can compute the $0-1$ sequence and go back and forth:

```
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: all(Partitions().from_zero_one(mu.zero_one_sequence())
....:     == mu for n in range(5) for mu in Partitions(n))
True
```

We can compute the Frobenius coordinates and go back and forth:

```
sage: Partition([7,3,1]).frobenius_coordinates()
([6, 1], [2, 0])
sage: Partition(frobenius_coordinates=([6,1],[2,0]))
[7, 3, 1]
sage: all(mu == Partition(frobenius_coordinates=mu.frobenius_coordinates())
....:     for n in range(30) for mu in Partitions(n))
True
```

We use the lexicographic ordering:

```
sage: pl = Partition([4,1,1])
sage: ql = Partitions()([3,3])
sage: pl > ql
True
sage: PL = Partitions()
sage: pl = PL([4,1,1])
sage: ql = PL([3,3])
sage: pl > ql
True
```

class sage.combinat.partition.**OrderedPartitions**(n, k)

Bases: sage.combinat.partition.Partitions

The class of ordered partitions of n. If k is specified, then this contains only the ordered partitions of length k.

An *ordered partition* of a nonnegative integer n means a list of positive integers whose sum is n. This is the same as a composition of n.

Note: It is recommended that you use `Compositions()` instead as `OrderedPartitions()` wraps GAP.

EXAMPLES:

```
sage: OrderedPartitions(3)
Ordered partitions of 3
sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2)
Ordered partitions of 3 of length 2
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]

sage: OrderedPartitions(10,k=2).list()
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]
sage: OrderedPartitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: OrderedPartitions(3).cardinality()
4
sage: OrderedPartitions(3,2).cardinality()
2
sage: OrderedPartitions(10,2).cardinality()
9
sage: OrderedPartitions(15).cardinality()
16384
```

list()

Return a list of partitions in `self`.

EXAMPLES:

```
sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]
```

class sage.combinat.partition.**Partition**(*parent*, *mu*)

Bases: sage.combinat.combinat.CombinatorialElement

A partition p of a nonnegative integer n is a non-increasing list of positive integers (the *parts* of the partition) with total sum n.

A partition is often represented as a diagram consisting of **cells**, or **boxes**, placed in rows on top of each other such that the number of cells in the i^{th} row, reading from top to bottom, is the i^{th} part of the partition. The rows are left-justified (and become shorter and shorter the farther down one goes). This diagram is called the **Young diagram** of the partition, or more precisely its Young diagram in English notation. (French and Russian notations are variations on this representation.)

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition `[5, 3, 1]` are `[[0,4], [1,2], [2,0]]`.

For display options, see `Partitions.global_options()`.

Note: Partitions are 0 based with coordinates in the form of (row-index, column-index). For example consider the partition `mu=Partition([4,3,2,2])`, the first part is `mu[0]` (which is 4), the second is `mu[1]`, and so on, and the upper-left cell in English convention is `(0, 0)`.

A partition can be specified in one of the following ways:

- a list (the default)
- using exponential notation
- by Frobenius coordinates
- specifying its $0-1$ sequence
- specifying the core and the quotient

See the examples below.

EXAMPLES:

Creating partitions though parents:

```
sage: mu = Partitions(8)([3,2,1,1,1]); mu
[3, 2, 1, 1, 1]
sage: nu = Partition([3,2,1,1,1]); nu
[3, 2, 1, 1, 1]
```

```
sage: mu == nu
True
sage: mu is nu
False
sage: mu in Partitions()
True
sage: mu.parent()
Partitions of the integer 8
sage: mu.size()
8
sage: mu.category()
Category of elements of Partitions of the integer 8
sage: nu.parent()
Partitions
sage: nu.category()
Category of elements of Partitions
sage: mu[0]
3
sage: mu[1]
2
sage: mu[2]
1
sage: mu.pp()
***
**
*
*
*
sage: mu.removable_cells()
[(0, 2), (1, 1), (4, 0)]
sage: mu.down_list()
[[2, 2, 1, 1, 1], [3, 1, 1, 1, 1], [3, 2, 1, 1]]
sage: mu.addable_cells()
[(0, 3), (1, 2), (2, 1), (5, 0)]
sage: mu.up_list()
[[4, 2, 1, 1, 1], [3, 3, 1, 1, 1], [3, 2, 2, 1, 1], [3, 2, 1, 1, 1, 1]]
sage: mu.conjugate()
[5, 2, 1]
sage: mu.dominates(nu)
True
sage: nu.dominates(mu)
True
```

Creating partitions using `Partition`:

```
sage: Partition([3,2,1])
[3, 2, 1]
sage: Partition(exp=[2,1,1])
[3, 2, 1, 1]
sage: Partition(core=[2,1], quotient=[[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
sage: Partition(frobenius_coordinates=([3,2],[4,0]))
[4, 4, 1, 1, 1]
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: [2,1] in Partitions()
True
sage: [2,1,0] in Partitions()
True
```

```
sage: Partition([1,2,3])
Traceback (most recent call last):
...
ValueError: [1, 2, 3] is not an element of Partitions
```

Sage ignores trailing zeros at the end of partitions:

```
sage: Partition([3,2,1,0])
[3, 2, 1]
sage: Partitions()([3,2,1,0])
[3, 2, 1]
sage: Partitions(6)([3,2,1,0])
[3, 2, 1]
```

TESTS:

Check that only trailing zeros are stripped:

```
sage: TestSuite( Partition([]) ).run()
sage: TestSuite( Partition([4,3,2,2,2,1]) ).run()
sage: Partition([3,2,2,2,1,0,0,0])
[3, 2, 2, 2, 1]
sage: Partition([3,0,2,2,2,1,0])
Traceback (most recent call last):
...
ValueError: [3, 0, 2, 2, 2, 1, 0] is not an element of Partitions
sage: Partition([0,7,3])
Traceback (most recent call last):
...
ValueError: [0, 7, 3] is not an element of Partitions
```

add_cell(*i*, *j=None*)

Return a partition corresponding to `self` with a cell added in row `i`. (This does not change `self`.)

EXAMPLES:

```
sage: Partition([3, 2, 1, 1]).add_cell(0)
[4, 2, 1, 1]
sage: cell = [4, 0]; Partition([3, 2, 1, 1]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

add_horizontal_border_strip(*k*)

Return a list of all the partitions that can be obtained by adding a horizontal border strip of length `k` to `self`.

EXAMPLES:

```
sage: Partition([]).add_horizontal_border_strip(0)
[[]]
sage: Partition([]).add_horizontal_border_strip(2)
[[2]]
sage: Partition([2,2]).add_horizontal_border_strip(2)
[[2, 2, 2], [3, 2, 1], [4, 2]]
sage: Partition([3,2,2]).add_horizontal_border_strip(2)
[[3, 2, 2, 2], [3, 3, 2, 1], [4, 2, 2, 1], [4, 3, 2], [5, 2, 2]]
```

Todo

Reimplement like `remove_horizontal_border_strip` using `IntegerListsLex`

---

add_vertical_border_strip(*k*)

Return a list of all the partitions that can be obtained by adding a vertical border strip of length `k` to `self`.

EXAMPLES:

```
sage: Partition([]).add_vertical_border_strip(0)
[[]]
sage: Partition([]).add_vertical_border_strip(2)
[[1, 1]]
sage: Partition([2,2]).add_vertical_border_strip(2)
[[3, 3], [3, 2, 1], [2, 2, 1, 1]]
sage: Partition([3,2,2]).add_vertical_border_strip(2)
[[4, 3, 2], [4, 2, 2, 1], [3, 3, 3], [3, 3, 2, 1], [3, 2, 2, 1, 1]]
```

addable_cells()

Return a list of the outside corners of the partition `self`.

An outside corner (also called a cocorner) of a partition λ is a cell on $\mathbf{Z}^2$ which does not belong to the Young diagram of λ but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
sage: Partition([]).outside_corners()
[(0, 0)]
```

addable_cells_residue(*i*, *l*)

Return a list of the outside corners of the partition `self` having `l`-residue `i`.

An outside corner (also called a cocorner) of a partition λ is a cell on $\mathbf{Z}^2$ which does not belong to the Young diagram of λ but can be added to this Young diagram to still form a straight-shape Young diagram. See `residue()` for the definition of the `l`-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]
sage: Partition([3,2,1]).outside_corners_residue(1, 3)
[(1, 2)]
sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]
```

arm_cells(*i*, *j*)

Return the list of the cells of the arm of cell (i, j) in `self`.

The arm of cell $c = (i, j)$ is the boxes that appear to the right of c.

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i, j` – two integers

OUTPUT:

A list of pairs of integers

EXAMPLES:

```
sage: Partition([4,4,3,1]).arm_cells(1,1)
[(1, 2), (1, 3)]

sage: Partition([]).arm_cells(0,0)
Traceback (most recent call last):
...
ValueError: The cell is not in the diagram
```

arm_length(*i*, *j*)

Return the length of the arm of cell (i, j) in `self`.

The arm of cell (i, j) is the cells that appear to the right of cell (i, j).

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i, j` – two integers

OUTPUT:

An integer or a `ValueError`

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.arm_length(0, 0)
1
sage: p.arm_length(0, 1)
0
sage: p.arm_length(2, 0)
0
sage: Partition([3,3]).arm_length(0, 0)
2
sage: Partition([3,3]).arm_length(*[0,0])
2
```

arm_lengths(*flat=False*)

Return a tableau of shape `self` where each cell is filled with its arm length. The optional boolean parameter `flat` provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).arm_lengths()
[[1, 0], [1, 0], [0]]
sage: Partition([2,2,1]).arm_lengths(flat=True)
[1, 0, 1, 0, 0]
sage: Partition([3,3]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
sage: Partition([3,3]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]
```

arms_legs_coeff(*i*, *j*)

This is a statistic on a cell $c = (i, j)$ in the diagram of partition p given by

$$\frac{1 - q^a \cdot t^{\ell+1}}{1 - q^{a+1} \cdot t^{\ell}}$$

where a is the arm length of c and ℓ is the leg length of c.

The coordinates `i` and `j` of the cell are understood to be 0-based, so that `(0, 0)` is the northwesternmost cell (in English notation).

EXAMPLES:

```
sage: Partition([3,2,1]).arms_legs_coeff(1,1)
(-t + 1)/(-q + 1)
sage: Partition([3,2,1]).arms_legs_coeff(0,0)
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
sage: Partition([3,2,1]).arms_legs_coeff(*[0,0])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
```

atom()

Return a list of the standard tableaux of size `self.size()` whose atom is equal to `self`.

EXAMPLES:

```
sage: Partition([2,1]).atom()
[[[1, 2], [3]]]
sage: Partition([3,2,1]).atom()
[[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]]
```

attacking_pairs()

Return a list of the attacking pairs of the Young diagram of `self`.

A pair of cells (c, d) of a Young diagram (in English notation) is said to be attacking if one of the following conditions holds:

1. c and d lie in the same row with c strictly to the west of d.

2. c is in the row immediately to the south of d, and c lies strictly east of d.

This particular method returns each pair (c, d) as a tuple, where each of c and d is given as a tuple (i, j) with i and j zero-based (so $i = 0$ means that the cell lies in the topmost row).

EXAMPLES:

```
sage: p = Partition([3, 2])
sage: p.attacking_pairs()
[((0, 0), (0, 1)),
 ((0, 0), (0, 2)),
 ((0, 1), (0, 2)),
 ((1, 0), (1, 1)),
 ((1, 1), (0, 0))]
sage: Partition([]).attacking_pairs()
[]
```

aut()

Return a factor for the number of permutations with cycle type `self`.

This method returns $1^{j_1} j_1! \cdots n^{j_n} j_n!$ where j_k is the number of parts in `self` equal to k.

The number of permutations having `self` as a cycle type is given by

$$\frac{n!}{1^{j_1} j_1! \cdots n^{j_n} j_n!}$$

(where n is the size of `self`).

EXAMPLES:

```
sage: Partition([2,1]).aut()
2
```

beta_numbers(*length=None*)

Return the set of beta numbers corresponding to `self`.

The optional argument `length` specifies the length of the beta set (which must be at least the length of `self`).

For more on beta numbers, see `frobenius_coordinates()`.

EXAMPLES:

```
sage: Partition([4,3,2]).beta_numbers()
[6, 4, 2]
sage: Partition([4,3,2]).beta_numbers(5)
[8, 6, 4, 1, 0]
sage: Partition([]).beta_numbers()
[]
sage: Partition([]).beta_numbers(3)
[2, 1, 0]
sage: Partition([6,4,1,1]).beta_numbers()
[9, 6, 2, 1]
sage: Partition([6,4,1,1]).beta_numbers(6)
[11, 8, 4, 3, 1, 0]
sage: Partition([1,1,1]).beta_numbers()
[3, 2, 1]
sage: Partition([1,1,1]).beta_numbers(4)
[4, 3, 2, 0]
```

cell_poset(*orientation='SE'*)

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to `"SE"`). Concretely, `orientation` has to be specified to one of the strings `"NW"`, `"NE"`, `"SW"`, and `"SE"`, standing for "northwest", "northeast", "southwest" and "southeast", respectively. If `orientation` is `"SE"`, then the order relation of the poset is such that a cell u is greater or equal to a cell v in the poset if and only if u lies weakly southeast of v (this means that u can be reached from v by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that $(3, 7)$ stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: p = Partition([3,3,1])
sage: Q = p.cell_poset(); Q
Finite poset containing 7 elements
sage: sorted(Q)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: Q.minimal_elements()
[(0, 0)]
sage: sorted(Q.upper_covers((1, 0)))
[(1, 1), (2, 0)]
sage: Q.upper_covers((1, 1))
```

```
[(1, 2)]

sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 7 elements
sage: sorted(P)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: P.maximal_elements()
[(0, 0)]
sage: P.upper_covers((2, 0))
[(1, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
sage: sorted(P.upper_covers((1, 1)))
[(0, 1), (1, 0)]
sage: sorted([len(P.upper_covers(v)) for v in P])
[0, 1, 1, 1, 1, 2, 2]

sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 7 elements
sage: sorted(R)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1, 1, 2, 2]
sage: R.is_isomorphic(P)
False
sage: R.is_isomorphic(P.dual())
False
```

Linear extensions of `p.cell_poset()` are in 1-to-1 correspondence with standard Young tableaux of shape p:

```
sage: all( len(p.cell_poset().linear_extensions())
....:      == len(p.standard_tableaux())
....:      for n in range(8) for p in Partitions(n) )
True
```

This is not the case for northeast orientation:

```
sage: q = Partition([3, 1])
sage: q.cell_poset(orientation="NE").is_chain()
True
```

TESTS:

We check that the posets are really what they should be for size up to 7:

```
sage: def check_NW(n):
....:     for p in Partitions(n):
....:         P = p.cell_poset(orientation="NW")
....:         for c in p.cells():
....:             for d in p.cells():
....:                 if P.le(c, d) != (c[0] >= d[0]
....:                                   and c[1] >= d[1]):
....:                     return False
```

```
....:     return True
sage: all( check_NW(n) for n in range(8) )
True

sage: def check_NE(n):
....:     for p in Partitions(n):
....:         P = p.cell_poset(orientation="NE")
....:         for c in p.cells():
....:             for d in p.cells():
....:                 if P.le(c, d) != (c[0] >= d[0]
....:                                   and c[1] <= d[1]):
....:                     return False
....:     return True
sage: all( check_NE(n) for n in range(8) )
True

sage: def test_duality(n, ori1, ori2):
....:     for p in Partitions(n):
....:         P = p.cell_poset(orientation=ori1)
....:         Q = p.cell_poset(orientation=ori2)
....:         for c in p.cells():
....:             for d in p.cells():
....:                 if P.lt(c, d) != Q.lt(d, c):
....:                     return False
....:     return True
sage: all( test_duality(n, "NW", "SE") for n in range(8) )
True
sage: all( test_duality(n, "NE", "SW") for n in range(8) )
True
sage: all( test_duality(n, "NE", "SE") for n in range(4) )
False
```

cells()

Return the coordinates of the cells of `self`.

EXAMPLES:

```
sage: Partition([2,2]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: Partition([3,2]).cells()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1)]
```

centralizer_size(*t=0*, *q=0*)

Return the size of the centralizer of any permutation of cycle type `self`.

If m_i is the multiplicity of i as a part of p, this is given by

$$\prod_i m_i! i^{m_i}.$$

Including the optional parameters t and q gives the $q-t$ analog which is the former product times

$$\prod_{i=1}^{\text{length}(p)} \frac{1-q^{p_i}}{1-t^{p_i}}.$$

See [Ker].

EXAMPLES:

```
sage: Partition([2,2,1]).centralizer_size()
8
sage: Partition([2,2,2]).centralizer_size()
48
sage: Partition([2,2,1]).centralizer_size(q=2, t=3)
9/16
sage: Partition([]).centralizer_size()
1
sage: Partition([]).centralizer_size(q=2, t=4)
1
```

character_polynomial()

Return the character polynomial associated to the partition `self`.

The character polynomial q_μ associated to a partition μ is defined by

$$q_\mu(x_1, x_2, \ldots, x_k) = \downarrow \sum_{\alpha \vdash k} \frac{\chi^\mu_\alpha}{1^{a_1} 2^{a_2} \cdots k^{a_k} a_1! a_2! \cdots a_k!} \prod_{i=1}^{k} (i x_i - 1)^{a_i}$$

where k is the size of μ, and a_i is the multiplicity of i in α.

It is computed in the following manner:

1. Expand the Schur function s_μ in the power-sum basis,
2. Replace each p_i with $ix_i - 1$,
3. Apply the umbral operator $\downarrow$ to the resulting polynomial.

EXAMPLES:

```
sage: Partition([1]).character_polynomial()
x - 1
sage: Partition([1,1]).character_polynomial()
1/2*x0^2 - 3/2*x0 - x1 + 1
sage: Partition([2,1]).character_polynomial()
1/3*x0^3 - 2*x0^2 + 8/3*x0 - x2
```

components()

Return a list containing the shape of `self`.

This method exists only for compatibility with `PartitionTuples`.

EXAMPLES:

```
sage: Partition([3,2]).components()
[[3, 2]]
```

conjugacy_class_size()

Return the size of the conjugacy class of the symmetric group indexed by `self`.

EXAMPLES:

```
sage: Partition([2,2,2]).conjugacy_class_size()
15
sage: Partition([2,2,1]).conjugacy_class_size()
15
sage: Partition([2,1,1]).conjugacy_class_size()
6
```

REFERENCES:

conjugate()

Return the conjugate partition of the partition `self`. This is also called the associated partition or the transpose in the literature.

EXAMPLES:

```
sage: Partition([2,2]).conjugate()
[2, 2]
sage: Partition([6,3,1]).conjugate()
[3, 2, 2, 1, 1, 1]
```

The conjugate partition is obtained by transposing the Ferrers diagram of the partition (see `ferrers_diagram()`):

```
sage: print Partition([6,3,1]).ferrers_diagram()
******
***
*
sage: print Partition([6,3,1]).conjugate().ferrers_diagram()
***
**
**
*
*
*
```

contains(x)

Return `True` if `x` is a partition whose Ferrers diagram is contained in the Ferrers diagram of `self`.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.contains([2,1])
True
sage: all(p.contains(mu) for mu in Partitions(3))
True
sage: all(p.contains(mu) for mu in Partitions(4))
False
```

content(*r, c, multicharge=[0]*)

Return the content of the cell at row r and column c.

The content of a cell is $c - r$.

For consistency with partition tuples there is also an optional `multicharge` argument which is an offset to the usual content. By setting the `multicharge` equal to the 0-element of the ring $\mathbf{Z}/e\mathbf{Z}$, the corresponding e-residue will be returned. This is the content modulo e.

The content (and residue) do not strictly depend on the partition, however, this method is included because it is often useful in the context of partitions.

EXAMPLES:

```
sage: Partition([2,1]).content(1,0)
-1
sage: p = Partition([3,2])
sage: sum([p.content(*c) for c in p.cells()])
2
```

and now we return the 3-residue of a cell:

```
sage: Partition([2,1]).content(1,0, multicharge=[IntegerModRing(3)(0)])
2
```

core(*length*)

Return the `length`-core of the partition – in the literature the core is commonly referred to as the k-core, p-core, r-core, ...

The r-core of a partition λ can be obtained by repeatedly removing rim hooks of size r from (the Young diagram of) λ until this is no longer possible. The remaining partition is the core.

EXAMPLES:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([]).core(3)
[]
sage: Partition([8,7,7,4,1,1,1,1,1]).core(3)
[2, 1, 1]
```

TESTS:

```
sage: Partition([3,3,3,2,1]).core(3)
[]
sage: Partition([10,8,7,7]).core(4)
[]
sage: Partition([21,15,15,9,6,6,6,3,3]).core(3)
[]
```

corners()

Return a list of the corners of the partition `self`.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

corners_residue(*i*, *l*)

Return a list of the corners of the partition `self` having `l`-residue `i`.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind. See `residue()` for the definition of the `l`-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
```

```
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

crank()

Return the Dyson crank of `self`.

The Dyson crank of a partition λ is defined as follows: If λ contains at least one 1, then the crank is $\mu(\lambda) - \omega(\lambda)$, where $\omega(\lambda)$ is the number of 1'sin'λ, and $\mu(\lambda)$ is the number of parts of λ larger than $\omega(\lambda)$. If λ contains no 1, then the crank is simply the largest part of λ.

REFERENCES:

EXAMPLES:

```
sage: Partition([]).crank()
0
sage: Partition([3,2,2]).crank()
3
sage: Partition([5,4,2,1,1]).crank()
0
sage: Partition([1,1,1]).crank()
-3
sage: Partition([6,4,4,3]).crank()
6
sage: Partition([6,3,3,1,1]).crank()
1
sage: Partition([6]).crank()
6
sage: Partition([5,1]).crank()
0
sage: Partition([4,2]).crank()
4
sage: Partition([4,1,1]).crank()
-1
sage: Partition([3,3]).crank()
3
sage: Partition([3,2,1]).crank()
1
sage: Partition([3,1,1,1]).crank()
-3
sage: Partition([2,2,2]).crank()
2
sage: Partition([2,2,1,1]).crank()
-2
sage: Partition([2,1,1,1,1]).crank()
-4
sage: Partition([1,1,1,1,1,1]).crank()
-6
```

dimension(*smaller=*[ ], *k=1*)

Return the number of paths from the `smaller` partition to the partition `self`, where each step consists of adding a k-ribbon while keeping a partition.

Note that a 1-ribbon is just a single cell, so this counts paths in the Young graph when $k = 1$.

Note also that the default case ($k = 1$ and `smaller = []`) gives the dimension of the irreducible representation of the symmetric group corresponding to `self`.

INPUT:

- `smaller` – a partition (default: an empty list `[]`)
- k – a positive integer (default: 1)

OUTPUT:

The number of such paths

EXAMPLES:

Looks at the number of ways of getting from `[5,4]` to the empty partition, removing one cell at a time:

```
sage: mu = Partition([5,4])
sage: mu.dimension()
42
```

Same, but removing one 3-ribbon at a time. Note that the 3-core of `mu` is empty:

```
sage: mu.dimension(k=3)
3
```

The 2-core of `mu` is not the empty partition:

```
sage: mu.dimension(k=2)
0
```

Indeed, the 2-core of `mu` is `[1]`:

```
sage: mu.dimension(Partition([1]),k=2)
2
```

TESTS:

Checks that the sum of squares of dimensions of characters of the symmetric group is the order of the group:

```
sage: all(sum(mu.dimension()^2 for mu in Partitions(i))==factorial(i) for i in range(10))
True
```

A check coming from the theory of k-differentiable posets:

```
sage: k=2; core = Partition([2,1])
sage: all(sum(mu.dimension(core,k=2)^2
....:         for mu in Partitions(3+i*2) if mu.core(2) == core)
....:     == 2^i*factorial(i) for i in range(10))
True
```

Checks that the dimension satisfies the obvious recursion relation:

```
sage: test = lambda larger, smaller: larger.dimension(smaller) == sum(mu.dimension(smaller)
sage: all(test(larger,smaller) for l in xrange(1,10) for s in xrange(0,10)
....:     for larger in Partitions(l) for smaller in Partitions(s) if smaller != larger)
True
```

ALGORITHM:

Depending on the parameters given, different simplifications occur. When $k = 1$ and `smaller` is empty, this function uses the hook formula. When $k = 1$ and `smaller` is not empty, it uses a formula from [ORV].

When $k \neq 1$, we first check that both `self` and `smaller` have the same k-core, then use the k-quotients and the same algorithm on each of the k-quotients.

dominated_partitions(*rows=None*)

Return a list of the partitions dominated by n. If `rows` is specified, then it only returns the ones whose number of rows is at most `rows`.

EXAMPLES:

```
sage: Partition([3,2,1]).dominated_partitions()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1]]
sage: Partition([3,2,1]).dominated_partitions(rows=3)
[[3, 2, 1], [2, 2, 2]]
```

dominates(*p2*)

Return `True` if `self` dominates the partition `p2`. Otherwise it returns `False`.

EXAMPLES:

```
sage: p = Partition([3,2])
sage: p.dominates([3,1])
True
sage: p.dominates([2,2])
True
sage: p.dominates([2,1,1])
True
sage: p.dominates([3,3])
False
sage: p.dominates([4])
False
sage: Partition([4]).dominates(p)
False
sage: Partition([]).dominates([1])
False
sage: Partition([]).dominates([])
True
sage: Partition([1]).dominates([])
True
```

down()

Return a generator for partitions that can be obtained from `self` by removing a cell.

EXAMPLES:

```
sage: [p for p in Partition([2,1,1]).down()]
[[1, 1, 1], [2, 1]]
sage: [p for p in Partition([3,2]).down()]
[[2, 2], [3, 1]]
sage: [p for p in Partition([3,2,1]).down()]
[[2, 2, 1], [3, 1, 1], [3, 2]]
```

TESTS:

We check that trac ticket #11435 is fixed:

```
sage: Partition([]).down_list() #indirect doctest
[]
```

down_list()

Return a list of the partitions that can be obtained from `self` by removing a cell.

EXAMPLES:

```
sage: Partition([2,1,1]).down_list()
[[1, 1, 1], [2, 1]]
sage: Partition([3,2]).down_list()
[[2, 2], [3, 1]]
sage: Partition([3,2,1]).down_list()
[[2, 2, 1], [3, 1, 1], [3, 2]]
sage: Partition([]).down_list()  # checks trac #11435
[]
```

dual_equivalence_graph(*directed=False*, *coloring=None*)

Return the dual equivalence graph of `self`.

Two permutations p and q in the symmetric group S_n differ by an *i-elementary dual equivalence (or dual Knuth) relation* (where i is an integer with $1 < i < n$) when the following two conditions are satisfied:

- In the one-line notation of the permutation p, the letter i does not appear inbetween $i-1$ and $i+1$.
- The permutation q is obtained from p by switching two of the three letters $i-1, i, i+1$ (in its one-line notation) – namely, the leftmost and the rightmost one in order of their appearance in p.

Notice that this is equivalent to the statement that the permutations p^{-1} and q^{-1} differ by an elementary Knuth equivalence at positions $i-1, i, i+1$.

Two standard Young tableaux of shape λ differ by an i-elementary dual equivalence relation (of color i), if their reading words differ by an i-elementary dual equivalence relation.

The *dual equivalence graph* of the partition λ is the edge-colored graph whose vertices are the standard Young tableaux of shape λ, and whose edges colored by i are given by the i-elementary dual equivalences.

INPUT:

- `directed` – (default: `False`) whether to have the dual equivalence graph be directed (where we have a directed edge $S \to T$ if i appears to the left of $i+1$ in the reading word of T; otherwise we have the directed edge $T \to S$)
- `coloring` – (optional) a function which sends each integer $i > 1$ to a color (as a string, e.g., `'red'` or `'black'`) to be used when visually representing the resulting graph using dot2tex; the default choice is `2 -> 'red', 3 -> 'blue', 4 -> 'green', 5 -> 'purple', 6 -> 'brown', 7 -> 'orange', 8 -> 'yellow', anything greater than 8 -> 'black'`.

REFERENCES:

EXAMPLES:

```
sage: P = Partition([3,1,1])
sage: G = P.dual_equivalence_graph()
sage: sorted(G.edges())
[([[1, 2, 3], [4], [5]], [[1, 2, 4], [3], [5]], 3),
 ([[1, 2, 4], [3], [5]], [[1, 2, 5], [3], [4]], 4),
 ([[1, 2, 4], [3], [5]], [[1, 3, 4], [2], [5]], 2),
 ([[1, 2, 5], [3], [4]], [[1, 3, 5], [2], [4]], 2),
 ([[1, 3, 4], [2], [5]], [[1, 3, 5], [2], [4]], 4),
 ([[1, 3, 5], [2], [4]], [[1, 4, 5], [2], [3]], 3)]
sage: G = P.dual_equivalence_graph(directed=True)
sage: sorted(G.edges())
[([[1, 2, 4], [3], [5]], [[1, 2, 3], [4], [5]], 3),
 ([[1, 2, 5], [3], [4]], [[1, 2, 4], [3], [5]], 4),
 ([[1, 3, 4], [2], [5]], [[1, 2, 4], [3], [5]], 2),
 ([[1, 3, 5], [2], [4]], [[1, 2, 5], [3], [4]], 2),
```

```
 ([[1, 3, 5], [2], [4]], [[1, 3, 4], [2], [5]], 4),
 ([[1, 4, 5], [2], [3]], [[1, 3, 5], [2], [4]], 3)]
```

TESTS:

```
sage: G = Partition([1]).dual_equivalence_graph()
sage: G.vertices()
[[[1]]]
sage: G = Partition([]).dual_equivalence_graph()
sage: G.vertices()
[[]]

sage: P = Partition([3,1,1])
sage: G = P.dual_equivalence_graph(coloring=lambda x: 'red')
sage: G2 = P.dual_equivalence_graph(coloring={2: 'black', 3: 'blue', 4: 'cyan', 5: 'grey'})
sage: G is G2
False
sage: G == G2
True
```

evaluation()

Return the evaluation of `self`.

The **commutative evaluation**, often shortened to **evaluation**, of a word (we think of a partition as a word in $\{1, 2, 3, \ldots\}$) is its image in the free commutative monoid. In other words, this counts how many occurrences there are of each letter.

This is also is known as **Parikh vector** and **abelianization** and has the same output as `to_exp()`.

EXAMPLES:

```
sage: Partition([4,3,1,1]).evaluation()
[2, 0, 1, 1]
```

ferrers_diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: mu=Partition([5,5,2,1])
sage: Partitions.global_options(diagram_str='*', convention="english")
sage: print mu.ferrers_diagram()
*****
*****
**
*
sage: Partitions.global_options(diagram_str='#')
sage: print mu.ferrers_diagram()
#####
#####
##
#
sage: Partitions.global_options(convention="french")
sage: print mu.ferrers_diagram()
#
##
#####
#####
sage: print Partition([]).ferrers_diagram()
-
```

```
sage: Partitions.global_options(diagram_str='-')
sage: print Partition([]).ferrers_diagram()
(/)
sage: Partitions.global_options.reset()
```

frobenius_coordinates()

Return a pair of sequences of Frobenius coordinates aka beta numbers of the partition.

These are two strictly decreasing sequences of nonnegative integers of the same length.

EXAMPLES:

```
sage: Partition([]).frobenius_coordinates()
([], [])
sage: Partition([1]).frobenius_coordinates()
([0], [0])
sage: Partition([3,3,3]).frobenius_coordinates()
([2, 1, 0], [2, 1, 0])
sage: Partition([9,1,1,1,1,1,1]).frobenius_coordinates()
([8], [6])
```

frobenius_rank()

Return the Frobenius rank of the partition `self`.

The Frobenius rank of a partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \cdots)$ is defined to be the largest i such that $\lambda_i \geq i$. In other words, it is the number of cells on the main diagonal of λ. In yet other words, it is the size of the largest square fitting into the Young diagram of λ.

EXAMPLES:

```
sage: Partition([]).frobenius_rank()
0
sage: Partition([1]).frobenius_rank()
1
sage: Partition([3,3,3]).frobenius_rank()
3
sage: Partition([9,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,2,1,1,1,1]).frobenius_rank()
2
sage: Partition([3,2]).frobenius_rank()
2
sage: Partition([3,2,2]).frobenius_rank()
2
sage: Partition([8,4,4,4,4]).frobenius_rank()
4
sage: Partition([8,4,1]).frobenius_rank()
2
sage: Partition([3,3,1]).frobenius_rank()
2
```

from_kbounded_to_grassmannian(k)

Maps a k-bounded partition to a Grassmannian element in the affine Weyl group of type $A_k^{(1)}$.

For details, see the documentation of the method `from_kbounded_to_reduced_word()` .

EXAMPLES:

```
sage: p=Partition([2,1,1])
sage: p.from_kbounded_to_grassmannian(2)
[-1  1  1]
[-2  2  1]
[-2  1  2]
sage: p=Partition([])
sage: p.from_kbounded_to_grassmannian(2)
[1 0 0]
[0 1 0]
[0 0 1]
```

from_kbounded_to_reduced_word(*k*)

Maps a k-bounded partition to a reduced word for an element in the affine permutation group.

This uses the fact that there is a bijection between k-bounded partitions and $(k+1)$-cores and an action of the affine nilCoxeter algebra of type $A_k^{(1)}$ on $(k+1)$-cores as described in [LM2006].

REFERENCES:

EXAMPLES:

```
sage: p=Partition([2,1,1])
sage: p.from_kbounded_to_reduced_word(2)
[2, 1, 2, 0]
sage: p=Partition([3,1])
sage: p.from_kbounded_to_reduced_word(3)
[3, 2, 1, 0]
sage: p.from_kbounded_to_reduced_word(2)
Traceback (most recent call last):
...
ValueError: the partition must be 2-bounded
sage: p=Partition([])
sage: p.from_kbounded_to_reduced_word(2)
[]
```

garnir_tableau(**cell*)

Return the Garnir tableau of shape `self` corresponding to the cell `cell`. If `cell` $= (a, c)$ then $(a+1, c)$ must belong to the diagram of `self`.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring.

The Garnir tableaux are the "first" non-standard tableaux which arise when you act by simple transpositions. If (a, c) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers $1, 2, \ldots, n$ entered in order from left to right along the rows of the diagram up to the cell $(a, c-1)$, then along the cells $(a+1, 1)$ to $(a+1, c)$, then (a, c) until the end of row a and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

Note: The function also sets `g._garnir_cell`, where `g` is the resulting Garnir tableau, equal to `cell` which is used by some other functions.

EXAMPLES:

```
sage: g=Partition([5,3,3,2]).garnir_tableau((0,2)); g.pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
```

```
sage: g.is_row_strict(); g.is_column_strict()
True
False

sage: Partition([5,3,3,2]).garnir_tableau(0,2).pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
sage: Partition([5,3,3,2]).garnir_tableau(2,1).pp()
  1  2  3  4  5
  6  7  8
  9 12 13
 10 11
sage: Partition([5,3,3,2]).garnir_tableau(2,2).pp()
Traceback (most recent call last):
...
ValueError: (row+1, col) must be inside the diagram
```

See also:

- top_garnir_tableau()

generalized_pochhammer_symbol(*a*, *alpha*)

Return the generalized Pochhammer symbol $(a)^{(\alpha)}_{self}$. This is the product over all cells (i,j) in self of $a-(i-1)/\alpha+j-1$.

EXAMPLES:

```
sage: Partition([2,2]).generalized_pochhammer_symbol(2,1)
12
```

get_part(*i*, *default=0*)

Return the i^{th} part of self, or default if it does not exist.

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.get_part(0), p.get_part(1), p.get_part(2)
(2, 1, 0)
sage: p.get_part(10,-1)
-1
sage: Partition([]).get_part(0)
0
```

hook_length(*i*, *j*)

Return the length of the hook of cell (i,j) in self.

The (length of the) hook of cell (i,j) of a partition λ is

$$\lambda_i + \lambda'_j - i - j + 1$$

where λ' is the conjugate partition. In English convention, the hook length is the number of cells horizontally to the right and vertically below the cell (i,j) (including that cell).

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.hook_length(0, 0)
4
```

```
sage: p.hook_length(0, 1)
2
sage: p.hook_length(2, 0)
1
sage: Partition([3,3]).hook_length(0, 0)
4
sage: cell = [0,0]; Partition([3,3]).hook_length(*cell)
4
```

hook_lengths()

Return a tableau of shape `self` with the cells filled in with the hook lengths.

In each cell, put the sum of one plus the number of cells horizontally to the right and vertically below the cell (the hook length).

For example, consider the partition `[3,2,1]` of 6 with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with the hook lengths, we obtain:

```
5 3 1
3 1
1
```

EXAMPLES:

```
sage: Partition([2,2,1]).hook_lengths()
[[4, 2], [3, 1], [1]]
sage: Partition([3,3]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: Partition([2,2]).hook_lengths()
[[3, 2], [2, 1]]
sage: Partition([5]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

REFERENCES:

- http://mathworld.wolfram.com/HookLengthFormula.html

hook_polynomial(q, t)

Return the two-variable hook polynomial.

EXAMPLES:

```
sage: R.<q,t> = PolynomialRing(QQ)
sage: a = Partition([2,2]).hook_polynomial(q,t)
sage: a == (1 - t)*(1 - q*t)*(1 - t^2)*(1 - q*t^2)
True
sage: a = Partition([3,2,1]).hook_polynomial(q,t)
sage: a == (1 - t)^3*(1 - q*t^2)^2*(1 - q^2*t^3)
True
```

hook_product(a)

Return the Jack hook-product.

EXAMPLES:

```
sage: Partition([3,2,1]).hook_product(x)
(2*x + 3)*(x + 2)^2
sage: Partition([2,2]).hook_product(x)
2*(x + 2)*(x + 1)
```

hooks()

Return a sorted list of the hook lengths in `self`.

EXAMPLES:

```
sage: Partition([3,2,1]).hooks()
[5, 3, 3, 1, 1, 1]
```

initial_tableau()

Return the `standard tableau` which has the numbers $1, 2, \ldots, n$ where n is the `size()` of `self` entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

```
sage: Partition([3,2,2]).initial_tableau()
[[1, 2, 3], [4, 5], [6, 7]]
```

inside_corners()

Return a list of the corners of the partition `self`.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

inside_corners_residue(i, l)

Return a list of the corners of the partition `self` having `l`-residue `i`.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind. See `residue()` for the definition of the `l`-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

is_core(k)

Tests whether the partition is a k-core or not. Visuallly, this can be checked by trying to remove border

strips of size k from `self`. If this is not possible, then `self` is a k-core.

A partition is said to be a *'k'-core* if it has no hooks of length k. Equivalently, a partition is said to be a k-core if it is its own k-core (where the latter is defined as in `core()`).

EXAMPLES:

```
sage: p = Partition([12,8,5,5,2,2,1])
sage: p.is_core(4)
False
sage: p.is_core(5)
True
sage: p.is_core(0)
True
```

is_empty()

Return `True` if `self` is the empty partition.

EXAMPLES:

```
sage: Partition([]).is_empty()
True
sage: Partition([2,1,1]).is_empty()
False
```

jacobi_trudi()

Return the Jacobi-Trudi matrix of `self` thought of as a skew partition. See `SkewPartition.jacobi_trudi()`.

EXAMPLES:

```
sage: part = Partition([3,2,1])
sage: jt = part.jacobi_trudi(); jt
[h[3] h[1]    0]
[h[4] h[2]  h[]]
[h[5] h[3] h[1]]
sage: s = SymmetricFunctions(QQ).schur()
sage: h = SymmetricFunctions(QQ).homogeneous()
sage: h( s(part) )
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
sage: jt.det()
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
```

k_atom(k)

Return a list of the standard tableaux of size `self.size()` whose `k`-atom is equal to `self`.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_atom(1)
[]
sage: p.k_atom(3)
[[[1, 1, 1], [2, 2], [3]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2, 3], [2]]]
sage: Partition([3,2,1]).k_atom(4)
[[[1, 1, 1], [2, 2], [3]], [[1, 1, 1, 3], [2, 2]]]
```

TESTS:

```
sage: Partition([1]).k_atom(1)
[[[1]]]
sage: Partition([1]).k_atom(2)
[[[1]]]
sage: Partition([]).k_atom(1)
[[]]
```

k_boundary(*k*)

Return the skew partition formed by removing the cells of the k-interior, see k_interior().

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_boundary(2)
[3, 2, 1] / [2, 1]
sage: p.k_boundary(3)
[3, 2, 1] / [1]

sage: p = Partition([12,8,5,5,2,2,1])
sage: p.k_boundary(4)
[12, 8, 5, 5, 2, 2, 1] / [8, 5, 2, 2]
```

k_conjugate(*k*)

Return the k-conjugate of self.

The k-conjugate is the partition that is given by the columns of the k-skew diagram of the partition.

We can also define the k-conjugate in the following way. Let P denote the bijection from $(k+1)$-cores to k-bounded partitions. The k-conjugate of a $(k+1)$-core λ is

$$\lambda^{(k)} = P^{-1}\left((P(\lambda))'\right).$$

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_conjugate(4)
[3, 2, 2, 1, 1, 1, 1, 1, 1]
```

k_interior(*k*)

Return the partition consisting of the cells of self whose hook lengths are greater than k.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: p.k_interior(2)
[2, 1]
sage: p.k_interior(3)
[1]

sage: p = Partition([])
sage: p.k_interior(3)
[]
```

k_irreducible(*k*)

Return the partition with all $r \times (k+1-r)$ rectangles removed.

If self is a k-bounded partition, then this method will return the partition where all rectangles of dimension $r \times (k+1-r)$ for $1 \leq r \leq k$ have been deleted.

If `self` is not a k-bounded partition then the method will raise an error.

INPUT:

- `k` – a non-negative integer

OUTPUT:

- a partition

EXAMPLES:

```
sage: Partition([3,2,2,1,1,1]).k_irreducible(4)
[3, 2, 2, 1, 1, 1]
sage: Partition([3,2,2,1,1,1]).k_irreducible(3)
[]
sage: Partition([3,3,3,2,2,2,2,2,1,1,1,1]).k_irreducible(3)
[2, 1]
```

k_skew(k)

Return the k-skew partition.

The k-skew diagram of a k-bounded partition is the skew diagram denoted $\lambda/^k$ satisfying the conditions:

1. row i of $\lambda/^k$ has length λ_i,
2. no cell in $\lambda/^k$ has hook-length exceeding k,
3. every square above the diagram of $\lambda/^k$ has hook length exceeding k.

REFERENCES:

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_skew(4)
[9, 5, 3, 2, 1, 1] / [5, 2, 1]
```

k_split(k)

Return the `k`-split of `self`.

EXAMPLES:

```
sage: Partition([4,3,2,1]).k_split(3)
[]
sage: Partition([4,3,2,1]).k_split(4)
[[4], [3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(5)
[[4, 3], [2, 1]]
sage: Partition([4,3,2,1]).k_split(6)
[[4, 3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(7)
[[4, 3, 2, 1]]
sage: Partition([4,3,2,1]).k_split(8)
[[4, 3, 2, 1]]
```

larger_lex(*rhs*)

Return `True` if `self` is larger than `rhs` in lexicographic order. Otherwise return `False`.

EXAMPLES:

```
sage: p = Partition([3,2])
sage: p.larger_lex([3,1])
True
sage: p.larger_lex([1,4])
```

```
True
sage: p.larger_lex([3,2,1])
False
sage: p.larger_lex([3])
True
sage: p.larger_lex([5])
False
sage: p.larger_lex([3,1,1,1,1,1,1,1])
True
```

leg_cells (i, j)

Return the list of the cells of the leg of cell (i, j) in `self`.

The leg of cell $c = (i, j)$ is defined to be the cells below c (in English convention).

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i, j` – two integers

OUTPUT:

A list of pairs of integers

EXAMPLES:

```
sage: Partition([4,4,3,1]).leg_cells(1,1)
[(2, 1)]
sage: Partition([4,4,3,1]).leg_cells(0,1)
[(1, 1), (2, 1)]

sage: Partition([]).leg_cells(0,0)
Traceback (most recent call last):
...
ValueError: The cell is not in the diagram
```

leg_length (i, j)

Return the length of the leg of cell (i, j) in `self`.

The leg of cell $c = (i, j)$ is defined to be the cells below c (in English convention).

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i, j` – two integers

OUTPUT:

An integer or a `ValueError`

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.leg_length(0, 0)
2
sage: p.leg_length(0,1)
1
sage: p.leg_length(2,0)
0
sage: Partition([3,3]).leg_length(0, 0)
1
```

```
sage: cell = [0,0]; Partition([3,3]).leg_length(*cell)
1
```

leg_lengths(*flat=False*)

Return a tableau of shape `self` with each cell filled in with its leg length. The optional boolean parameter `flat` provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).leg_lengths()
[[2, 1], [1, 0], [0]]
sage: Partition([2,2,1]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]
sage: Partition([3,3]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
sage: Partition([3,3]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

length()

Return the number of parts in `self`.

EXAMPLES:

```
sage: Partition([3,2]).length()
2
sage: Partition([2,2,1]).length()
3
sage: Partition([]).length()
0
```

level()

Return the level of `self`, which is always 1.

This method exists only for compatibility with `PartitionTuples`.

EXAMPLE:

```
sage: Partition([4,3,2]).level()
1
```

lower_hook(*i*, *j*, *alpha*)

Return the lower hook length of the cell (i, j) in `self`. When `alpha = 1`, this is just the normal hook length.

The lower hook length of a cell (i, j) in a partition κ is defined by

$$h^\kappa_*(i, j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.lower_hook(0,0,1)
3
sage: p.hook_length(0,0)
3
sage: [ p.lower_hook(i,j,x) for i,j in p.cells() ]
[x + 2, 1, 1]
```

lower_hook_lengths(*alpha*)

Return a tableau of shape `self` with the cells filled in with the lower hook lengths. When `alpha = 1`, these are just the normal hook lengths.

The lower hook length of a cell (i, j) in a partition κ is defined by

$$h_*^\kappa(i,j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

EXAMPLES:

```
sage: Partition([3,2,1]).lower_hook_lengths(x)
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
sage: Partition([3,2,1]).lower_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

next()

Return the partition that lexicographically follows `self`. If `self` is the last partition, then return `False`.

EXAMPLES:

```
sage: next(Partition([4]))
[3, 1]
sage: next(Partition([1,1,1,1]))
False
```

outer_rim()

Return the outer rim of `self`.

The outer rim of a partition λ is defined as the cells which do not belong to λ and which are adjacent to cells in λ.

EXAMPLES:

The outer rim of the partition $[4, 1]$ consists of the cells marked with `#` below:

```
****#
*####
##
```

```
sage: Partition([4,1]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]

sage: Partition([2,2,1]).outer_rim()
[(3, 0), (3, 1), (2, 1), (2, 2), (1, 2), (0, 2)]
sage: Partition([2,2]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]
sage: Partition([6,3,3,1,1]).outer_rim()
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1, 5), (1, 6), (0,
sage: Partition([]).outer_rim()
[(0, 0)]
```

outline(*variable=x*)

Return the outline of the partition `self`.

This is a piecewise linear function, normalized so that the area under the partition `[1]` is 2.

INPUT:

- variable – a variable (default: `'x'` in the symbolic ring)

EXAMPLES:

```
sage: [Partition([5,4]).outline()(x=i) for i in range(-10,11)]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
sage: Partition([]).outline()
abs(x)

sage: Partition([1]).outline()
abs(x + 1) + abs(x - 1) - abs(x)

sage: y=sage.symbolic.ring.var("y")
sage: Partition([6,5,1]).outline(variable=y)
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3) + abs(y - 1) - abs(y - 2) + abs(y - 3)
```

TESTS:

```
sage: integrate(Partition([1]).outline()-abs(x),(x,-10,10))
2
```

outside_corners()

Return a list of the outside corners of the partition `self`.

An outside corner (also called a cocorner) of a partition λ is a cell on $\mathbf{Z}^2$ which does not belong to the Young diagram of λ but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
sage: Partition([]).outside_corners()
[(0, 0)]
```

outside_corners_residue(i, l)

Return a list of the outside corners of the partition `self` having `l`-residue `i`.

An outside corner (also called a cocorner) of a partition λ is a cell on $\mathbf{Z}^2$ which does not belong to the Young diagram of λ but can be added to this Young diagram to still form a straight-shape Young diagram. See `residue()` for the definition of the `l`-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]
sage: Partition([3,2,1]).outside_corners_residue(1, 3)
[(1, 2)]
sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]
```

plancherel_measure()

Return the probability of `self` under the Plancherel probability measure on partitions of the same size.

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and `Partitions_n.random_element_plancherel()`.

EXAMPLES:

```
sage: Partition([]).plancherel_measure()
1
sage: Partition([1]).plancherel_measure()
1
sage: Partition([2]).plancherel_measure()
1/2
sage: [mu.plancherel_measure() for mu in Partitions(3)]
[1/6, 2/3, 1/6]
sage: Partition([5,4]).plancherel_measure()
7/1440
```

TESTS:

```
sage: all(sum(mu.plancherel_measure() for mu in Partitions(n))==1 for n in range(10))
True
```

power(k)

Return the cycle type of the k-th power of any permutation with cycle type `self` (thus describes the powermap of symmetric groups).

Equivalent to GAP's `PowerPartition`.

EXAMPLES:

```
sage: p = Partition([5,3])
sage: p.power(1)
[5, 3]
sage: p.power(2)
[5, 3]
sage: p.power(3)
[5, 1, 1, 1]
sage: p.power(4)
[5, 3]
```

Now let us compare this to the power map on S_8:

```
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)])
sage: g
(1,2,3,4,5)(6,7,8)
sage: g^2
(1,3,5,2,4)(6,8,7)
sage: g^3
(1,4,2,5,3)
sage: g^4
(1,5,4,3,2)(6,7,8)

sage: Partition([3,2,1]).power(3)
[2, 1, 1, 1, 1]
```

pp()

Prints the Ferrers diagram.

See `ferrers_diagram()` for more on the Ferrers diagram.

EXAMPLES:

```
sage: Partition([5,5,2,1]).pp()
*****
*****
```

```
**
*
sage: Partitions.global_options(convention='French')
sage: Partition([5,5,2,1]).pp()
*
**
*****
*****
sage: Partitions.global_options.reset()
```

quotient(*length*)

Return the quotient of the partition – in the literature the quotient is commonly referred to as the k-quotient, p-quotient, r-quotient, ...

The r-quotient of a partition λ is a list of r partitions (labelled from 0 to $r-1$), constructed in the following way. Label each cell in the Young diagram of λ with its content modulo r. Let R_i be the set of rows ending in a cell labelled i, and C_i be the set of columns ending in a cell labelled i. Then the j-th component of the quotient of λ is the partition defined by intersecting R_j with C_{j+1}. (See Theorem 2.7.37 in [JamesKerber].)

REFERENCES:

EXAMPLES:

```
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([2], [1], [2, 2, 2])
```

TESTS:

```
sage: Partition([8,7,7,4,1,1,1,1,1]).quotient(3)
([2, 1], [2, 2], [2])
sage: Partition([10,8,7,7]).quotient(4)
([2], [3], [2], [1])
sage: Partition([6,3,3]).quotient(3)
([1], [1], [2])
sage: Partition([3,3,3,2,1]).quotient(3)
([1], [1, 1], [1])
sage: Partition([6,6,6,3,3,3]).quotient(3)
([2, 1], [2, 1], [2, 1])
sage: Partition([21,15,15,9,6,6,6,3,3]).quotient(3)
([5, 2, 1], [5, 2, 1], [7, 3, 2])
sage: Partition([21,15,15,9,6,6,3,3]).quotient(3)
([5, 2], [5, 2, 1], [7, 3, 1])
sage: Partition([14,12,11,10,10,10,10,9,6,4,3,3,2,1]).quotient(5)
([3, 3], [2, 2, 1], [], [3, 3, 3], [1])

sage: all(p == Partition(core=p.core(k), quotient=p.quotient(k))
....:     for i in range(10) for p in Partitions(i)
....:     for k in range(1,6))
True
```

reading_tableau()

Return the RSK recording tableau of the reading word of the (standard) tableau T labeled down (in English convention) each column to the shape of `self`.

For an example of the tableau T, consider the partition $\lambda = (3, 2, 1)$, then we have:

```
1 4 6
2 5
3
```

For more, see RSK().

EXAMPLES:

```
sage: Partition([3,2,1]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

removable_cells()

Return a list of the corners of the partition self.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

removable_cells_residue(i, l)

Return a list of the corners of the partition self having l-residue i.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind. See residue() for the definition of the l-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

remove_cell(i, *j=None*)

Return the partition obtained by removing a cell at the end of row i of self.

EXAMPLES:

```
sage: Partition([2,2]).remove_cell(1)
[2, 1]
sage: Partition([2,2,1]).remove_cell(2)
[2, 2]
sage: #Partition([2,2]).remove_cell(0)

sage: Partition([2,2]).remove_cell(1,1)
[2, 1]
sage: #Partition([2,2]).remove_cell(1,0)
```

remove_horizontal_border_strip(k)

Return the partitions obtained from self by removing an horizontal border strip of length k.

EXAMPLES:

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(0).list()
[[5, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(1).list()
[[5, 3], [5, 2, 1], [4, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(2).list()
[[5, 2], [5, 1, 1], [4, 3], [4, 2, 1], [3, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(3).list()
[[5, 1], [4, 2], [4, 1, 1], [3, 3], [3, 2, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(4).list()
[[4, 1], [3, 2], [3, 1, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(5).list()
[[3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(6).list()
[]
```

The result is returned as an instance of `Partitions_with_constraints`:

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(5)
The subpartitions of [5, 3, 1] obtained by removing an horizontal border strip of length 5
```

TESTS:

```
sage: Partition([3,2,2]).remove_horizontal_border_strip(2).list()
[[3, 2], [2, 2, 1]]
sage: Partition([3,2,2]).remove_horizontal_border_strip(2).first().parent()
The subpartitions of [3, 2, 2] obtained by removing an horizontal border strip of length 2
sage: Partition([]).remove_horizontal_border_strip(0).list()
[[]]
sage: Partition([]).remove_horizontal_border_strip(6).list()
[]
```

residue(r, c, l)

Return the `l`-residue of the cell at row `r` and column `c`.

The ℓ-residue of a cell is $c - r$ modulo ℓ.

This does not strictly depend upon the partition, however, this method is included because it is often useful in the context of partitions.

EXAMPLES:

```
sage: Partition([2,1]).residue(1, 0, 3)
2
```

rim()

Return the rim of `self`.

The rim of a partition λ is defined as the cells which belong to λ and which are adjacent to cells not in λ.

EXAMPLES:

The rim of the partition $[5, 5, 2, 1]$ consists of the cells marked with # below:

```
****#
*####
##
#
```

```
sage: Partition([5,5,2,1]).rim()
[(3, 0), (2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]
```

```
sage: Partition([2,2,1]).rim()
```

```
[(2, 0), (1, 0), (1, 1), (0, 1)]
sage: Partition([2,2]).rim()
[(1, 0), (1, 1), (0, 1)]
sage: Partition([6,3,3,1,1]).rim()
[(4, 0), (3, 0), (2, 0), (2, 1), (2, 2), (1, 2), (0, 2), (0, 3), (0, 4), (0, 5)]
sage: Partition([]).rim()
[]
```

sign()

Return the sign of any permutation with cycle type `self`.

This function corresponds to a homomorphism from the symmetric group S_n into the cyclic group of order 2, whose kernel is exactly the alternating group A_n. Partitions of sign 1 are called even partitions while partitions of sign -1 are called odd.

EXAMPLES:

```
sage: Partition([5,3]).sign()
1
sage: Partition([5,2]).sign()
-1
```

Zolotarev's lemma states that the Legendre symbol $\left(\frac{a}{p}\right)$ for an integer $a \pmod p$ (p a prime number), can be computed as sign(p_a), where sign denotes the sign of a permutation and p_a the permutation of the residue classes $\pmod p$ induced by modular multiplication by a, provided p does not divide a.

We verify this in some examples.

```
sage: F = GF(11)
sage: a = F.multiplicative_generator();a
2
sage: plist = [int(a*F(x)) for x in range(1,11)]; plist
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
```

This corresponds to the permutation (1, 2, 4, 8, 5, 10, 9, 7, 3, 6) (acting the set $\{1, 2, ..., 10\}$) and to the partition [10].

```
sage: p = PermutationGroupElement('(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)')
sage: p.sign()
-1
sage: Partition([10]).sign()
-1
sage: kronecker_symbol(11,2)
-1
```

Now replace 2 by 3:

```
sage: plist = [int(F(3*x)) for x in range(1,11)]; plist
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
sage: range(1,11)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: p = PermutationGroupElement('(3,4,8,7,9)')
sage: p.sign()
1
sage: kronecker_symbol(3,11)
1
sage: Partition([5,1,1,1,1,1]).sign()
1
```

In both cases, Zolotarev holds.

REFERENCES:

Wikipedia article Zolotarev's_lemma

size()

Return the size of `self`.

EXAMPLES:

```
sage: Partition([2,2]).size()
4
sage: Partition([3,2,1]).size()
6
```

standard_tableaux()

Return the `standard tableaux` of this shape.

EXAMPLE:

```
sage: Partition([3,2,2,1]).standard_tableaux()
Standard tableaux of shape [3, 2, 2, 1]
```

suter_diagonal_slide(*n*, *exp=1*)

Return the image of `self` in Y_n under Suter's diagonal slide σ_n, where the notations used are those defined in [Sut2002].

The set Y_n is defined as the set of all partitions λ such that the hook length of the $(0,0)$-cell (i.e. the northwestern most cell in English notation) of λ is less than n, including the empty partition.

The map σ_n sends a partition (with non-zero entries) $(\lambda_1, \lambda_2, \ldots, \lambda_m) \in Y_n$ to the partition $(\lambda_2+1, \lambda_3+1, \ldots, \lambda_m+1, \underbrace{1, 1, \ldots, 1}_{n-m-\lambda_1 \text{ ones}})$. In other words, it pads the partition with trailing zeroes until it has length $n-\lambda_1$, then removes its first part, and finally adds 1 to each part.

By Theorem 2.1 of [Sut2002], the dihedral group D_n with $2n$ elements acts on Y_n by letting the primitive rotation act as σ_n and the reflection act as conjugation of partitions (`conjugate()`). This action is faithful if $n \geq 3$.

INPUT:

- `n` – nonnegative integer
- `exp` – (default: 1) how many times σ_n should be applied

OUTPUT:

The result of applying Suter's diagonal slide σ_n to `self`, assuming that `self` lies in Y_n. If the optional argument `exp` is set, then the slide σ_n is applied not just once, but `exp` times (note that `exp` is allowed to be negative, since the slide has finite order).

EXAMPLES:

```
sage: Partition([5,4,1]).suter_diagonal_slide(8)
[5, 2]
sage: Partition([5,4,1]).suter_diagonal_slide(9)
[5, 2, 1]
sage: Partition([]).suter_diagonal_slide(7)
[1, 1, 1, 1, 1, 1]
sage: Partition([]).suter_diagonal_slide(1)
[]
sage: Partition([]).suter_diagonal_slide(7, exp=-1)
[6]
sage: Partition([]).suter_diagonal_slide(1, exp=-1)
[]
```

```
sage: P7 = Partitions(7)
sage: all( p == p.suter_diagonal_slide(9, exp=-1).suter_diagonal_slide(9)
....:      for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=3)
....:            .suter_diagonal_slide(9, exp=3)
....:            .suter_diagonal_slide(9, exp=3)
....:      for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=6)
....:            .suter_diagonal_slide(9, exp=6)
....:            .suter_diagonal_slide(9, exp=6)
....:      for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=-1)
....:            .suter_diagonal_slide(9, exp=1)
....:      for p in P7 )
True
```

Check of the assertion in [Sut2002] that $\sigma_n(\sigma_n(\lambda')') = \lambda$:

```
sage: all( p.suter_diagonal_slide(8).conjugate()
....:      == p.conjugate().suter_diagonal_slide(8, exp=-1)
....:      for p in P7 )
True
```

Check of Claim 1 in [Sut2002]:

```
sage: P5 = Partitions(5)
sage: all( all( (p.suter_diagonal_slide(6) in q.suter_diagonal_slide(6).down())
....:           or (q.suter_diagonal_slide(6) in p.suter_diagonal_slide(6).down())
....:           for p in q.down() )
....:      for q in P5 )
True
```

TESTS:

Check for `exp = 0`:

```
sage: P = Partitions(4)
sage: all(p == p.suter_diagonal_slide(7, 0) for p in P)
True
```

Check for invalid input:

```
sage: p = Partition([2,1])
sage: p.hook_length(0, 0)
3
sage: p.suter_diagonal_slide(2)
Traceback (most recent call last):
...
ValueError: the hook length must be less than n
```

REFERENCES:

t_completion(t)

Return the `t`-completion of the partition `self`.

If $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ is a partition and t is an integer greater or equal to $|\lambda| + \lambda_1$, then the *t-completion of λ* is defined as the partition $(t - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)$ of t. This partition is denoted by $\lambda[t]$ in [BOR09], by $\lambda_{[t]}$ in [BdVO12], and by $\lambda(t)$ in [CO10].

REFERENCES:

EXAMPLES:

```
sage: Partition([]).t_completion(0)
[]
sage: Partition([]).t_completion(1)
[1]
sage: Partition([]).t_completion(2)
[2]
sage: Partition([]).t_completion(3)
[3]
sage: Partition([2, 1]).t_completion(5)
[2, 2, 1]
sage: Partition([2, 1]).t_completion(6)
[3, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(13)
[4, 4, 2, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(19)
[10, 4, 2, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(10)
Traceback (most recent call last):
...
ValueError: 10-completion is not defined
sage: Partition([4, 2, 2, 1]).t_completion(5)
Traceback (most recent call last):
...
ValueError: 5-completion is not defined
```

to_core(k)

Maps the k-bounded partition `self` to its corresponding $k+1$-core.

See also `k_skew()`.

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: c = p.to_core(4); c
[9, 5, 3, 2, 1, 1]
sage: type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: c.to_bounded_partition() == p
True
```

to_dyck_word(*n=None*)

Return the `n`-Dyck word whose corresponding partition is `self` (or, if `n` is not specified, the n-Dyck word with smallest n to satisfy this property).

If w is an n-Dyck word (that is, a Dyck word with n open symbols and n close symbols), then the Dyck path corresponding to w can be regarded as a lattice path in the northeastern half of an $n \times n$-square. The region to the northeast of this Dyck path can be regarded as a partition. It is called the partition corresponding to the Dyck word w. (See `to_partition()`.)

For every partition λ and every nonnegative integer n, there exists at most one n-Dyck word w such that the partition corresponding to w is λ (in fact, such w exists if and only if $\lambda_i + i \leq n$ for every i, where λ is written in the form $(\lambda_1, \lambda_2, \ldots, \lambda_k)$ with $\lambda_k > 0$). This method computes this w for a given λ and n. If n is not specified, this method computes the w for the smallest possible n for which such an w exists. (The minimality of n means that the partition demarcated by the Dyck path touches the diagonal.)

EXAMPLES:

```
sage: Partition([2,2]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(4)
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(5)
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: Partition([6,3,1]).to_dyck_word()
[1, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
sage: Partition([]).to_dyck_word()
[]
sage: Partition([]).to_dyck_word(3)
[1, 1, 1, 0, 0, 0]
```

The partition corresponding to `self.dyck_word()` is `self` indeed:

```
sage: all( p.to_dyck_word().to_partition() == p
....:      for p in Partitions(5) )
True
```

to_exp(*k=0*)

Return a list of the multiplicities of the parts of a partition. Use the optional parameter `k` to get a return list of length at least `k`.

EXAMPLES:

```
sage: Partition([3,2,2,1]).to_exp()
[1, 2, 1]
sage: Partition([3,2,2,1]).to_exp(5)
[1, 2, 1, 0, 0]
```

TESTS:

```
sage: [parent(x) for x in Partition([3,2,2,1]).to_exp(5)]
[Integer Ring, Integer Ring, Integer Ring, Integer Ring, Integer Ring]
```

to_exp_dict()

Return a dictionary containing the multiplicities of the parts of `self`.

EXAMPLES:

```
sage: p = Partition([4,2,2,1])
sage: d = p.to_exp_dict()
sage: d[4]
1
sage: d[2]
2
sage: d[1]
1
sage: 5 in d
False
```

to_list()

Return `self` as a list.

EXAMPLES:

```
sage: p = Partition([2,1]).to_list(); p
[2, 1]
sage: type(p)
<type 'list'>
```

TESTS:

```
sage: p = Partition([2,1])
sage: pl = p.to_list()
sage: pl[0] = 0; p
[2, 1]
```

top_garnir_tableau(*e*, *cell*)

Return the most dominant *standard* tableau which dominates the corresponding Garnir tableau and has the same `e`-residue.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules. The *top Garnir tableaux* arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR].

If the Garnir node is `cell=(r,c)` and m and M are the entries in the cells `(r,c)` and `(r+1,c)`, respectively, in the initial tableau then the top `e`-Garnir tableau is obtained by inserting the numbers $m, m+1, \ldots, M$ in order from left to right first in the cells in row `r+1` which are not in the `e`-Garnir belt, then in the cell in rows `r` and `r+1` which are in the Garnir belt and then, finally, in the remaining cells in row `r` which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If `e = 0`, or if there are no `e`-bricks in either row `r` or `r+1`, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```
sage: Partition([5,4,3,2]).top_garnir_tableau(2,(0,2)).pp()
   1  2  4  5  8
   3  6  7  9
  10 11 12
  13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(3,(0,2)).pp()
   1  2  3  4  5
   6  7  8  9
  10 11 12
  13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(4,(0,2)).pp()
   1  2  6  7  8
   3  4  5  9
  10 11 12
  13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(0,(0,2)).pp()
   1  2  6  7  8
   3  4  5  9
  10 11 12
  13 14
```

TESTS:

```
sage: Partition([5,4,3,2]).top_garnir_tableau(0,(3,2)).pp()
Traceback (most recent call last):
...
ValueError: (4,2)=(row+1,col) must be inside the diagram
```

REFERENCE:

- [KMR]

up()

Returns a generator for partitions that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: [p for p in Partition([2,1,1]).up()]
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: [p for p in Partition([3,2]).up()]
[[4, 2], [3, 3], [3, 2, 1]]
sage: [p for p in Partition([]).up()]
[[1]]
```

up_list()

Return a list of the partitions that can be formed from `self` by adding a cell.

EXAMPLES:

```
sage: Partition([2,1,1]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partition([3,2]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
sage: Partition([]).up_list()
[[1]]
```

upper_hook(*i*, *j*, *alpha*)

Return the upper hook length of the cell (i, j) in `self`. When `alpha = 1`, this is just the normal hook length.

The upper hook length of a cell (i, j) in a partition κ is defined by

$$h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.upper_hook(0,0,1)
3
sage: p.hook_length(0,0)
3
sage: [ p.upper_hook(i,j,x) for i,j in p.cells() ]
[2*x + 1, x, x]
```

upper_hook_lengths(*alpha*)

Return a tableau of shape `self` with the cells filled in with the upper hook lengths. When `alpha = 1`, these are just the normal hook lengths.

The upper hook length of a cell (i, j) in a partition κ is defined by

$$h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

```
sage: Partition([3,2,1]).upper_hook_lengths(x)
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
sage: Partition([3,2,1]).upper_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

weighted_size()

Return the weighted size of `self`.

The weighted size of a partition λ is

$$\sum_i i \cdot \lambda_i,$$

where $\lambda = (\lambda_0, \lambda_1, \lambda_2, \cdots)$.

This also the sum of the leg length of every cell in λ, or

$$\sum_i \binom{\lambda'_i}{2}$$

where λ' is the conjugate partition of λ.

EXAMPLES:

```
sage: Partition([2,2]).weighted_size()
2
sage: Partition([3,3,3]).weighted_size()
9
sage: Partition([5,2]).weighted_size()
2
sage: Partition([]).weighted_size()
0
```

young_subgroup()

Return the corresponding Young, or parabolic, subgroup of the symmetric group.

The Young subgroup of a partition $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ of n is the group:

$$S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell}$$

embedded into S_n in the standard way (i.e., the S_{λ_i} factor acts on the numbers from $\lambda_1+\lambda_2+\cdots+\lambda_{i-1}+1$ to $\lambda_1 + \lambda_2 + \cdots + \lambda_i$).

EXAMPLES:

```
sage: Partition([4,2]).young_subgroup()
Permutation Group with generators [(), (5,6), (3,4), (2,3), (1,2)]
```

young_subgroup_generators()

Return an indexing set for the generators of the corresponding Young subgroup. Here the generators correspond to the simple adjacent transpositions $s_i = (i\ i+1)$.

EXAMPLES:

```
sage: Partition([4,2]).young_subgroup_generators()
[1, 2, 3, 5]
sage: Partition([1,1,1]).young_subgroup_generators()
[]
sage: Partition([2,2]).young_subgroup_generators()
[1, 3]
```

zero_one_sequence()

Compute the finite $0-1$ sequence of the partition.

The full $0-1$ sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full $0-1$ sequence starts with infinitely many 0's and ends with infinitely many 1's.

One place where these arise is in the affine symmetric group where one takes an affine permutation w and every i such that $w(i) \leq 0$ corresponds to a 1 and $w(i) > 0$ corresponds to a 0. See pages 24-25 of [LLMMSZ13] for connections to affine Grassmannian elements (note there they use the French convention for their partitions).

These are also known as **path sequences**, **Maya diagrams**, **plus-minus diagrams**, **Comet code** [Sta-EC2], among others.

OUTPUT:

The finite $0-1$ sequence is obtained from the full $0-1$ sequence by omitting all heading 0's and trailing 1's. The output sequence is finite, starts with a 1 and ends with a 0 (unless it is empty, for the empty partition). Its length is the sum of the first part of the partition with the length of the partition.

REFERENCES:

EXAMPLES:

```
sage: Partition([5,4]).zero_one_sequence()
[1, 1, 1, 1, 0, 1, 0]
sage: Partition([]).zero_one_sequence()
[]
sage: Partition([2]).zero_one_sequence()
[1, 1, 0]
```

TESTS:

```
sage: all(Partitions().from_zero_one(mu.zero_one_sequence()) == mu for n in range(10) for mu
True
```

class sage.combinat.partition.**Partitions**(*is_infinite=False*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

`Partitions(n, **kwargs)` returns the combinatorial class of integer partitions of n subject to the constraints given by the keywords.

Valid keywords are: `starting`, `ending`, `min_part`, `max_part`, `max_length`, `min_length`, `length`, `max_slope`, `min_slope`, `inner`, `outer`, `parts_in` and `regular`. They have the following meanings:

- `starting=p` specifies that the partitions should all be less than or equal to p in lex order. This argument cannot be combined with any other (see trac ticket #15467).
- `ending=p` specifies that the partitions should all be greater than or equal to p in lex order. This argument cannot be combined with any other (see trac ticket #15467).
- `length=k` specifies that the partitions have exactly k parts.
- `min_length=k` specifies that the partitions have at least k parts.
- `min_part=k` specifies that all parts of the partitions are at least k.
- `inner=p` specifies that the partitions must contain the partition p.
- `outer=p` specifies that the partitions be contained inside the partition p.
- `min_slope=k` specifies that the partitions have slope at least k; the slope at position i is the difference between the $(i+1)$-th part and the i-th part.
- `parts_in=S` specifies that the partitions have parts in the set S, which can be any sequence of pairwise distinct positive integers. This argument cannot be combined with any other (see trac ticket #15467).
- `regular=ell` specifies that the partitions are ℓ-regular, and can only be combined with the `max_length` or `max_part`, but not both, keywords if n is not specified

The `max_*` versions, along with `inner` and `ending`, work analogously.

Right now, the `parts_in`, `starting`, `ending`, and `regular` keyword arguments are mutually exclusive, both of each other and of other keyword arguments. If you specify, say, `parts_in`, all other keyword arguments will be ignored; `starting`, `ending`, and `regular` work the same way.

EXAMPLES:

If no arguments are passed, then the combinatorial class of all integer partitions is returned:

```
sage: Partitions()
Partitions
sage: [2,1] in Partitions()
True
```

If an integer n is passed, then the combinatorial class of integer partitions of n is returned:

```
sage: Partitions(3)
Partitions of the integer 3
sage: Partitions(3).list()
[[3], [2, 1], [1, 1, 1]]
```

If `starting=p` is passed, then the combinatorial class of partitions greater than or equal to p in lexicographic order is returned:

```
sage: Partitions(3, starting=[2,1])
Partitions of the integer 3 starting with [2, 1]
sage: Partitions(3, starting=[2,1]).list()
[[2, 1], [1, 1, 1]]
```

If `ending=p` is passed, then the combinatorial class of partitions at most p in lexicographic order is returned:

```
sage: Partitions(3, ending=[2,1])
Partitions of the integer 3 ending with [2, 1]
sage: Partitions(3, ending=[2,1]).list()
[[3], [2, 1]]
```

Using `max_slope=-1` yields partitions into distinct parts – each part differs from the next by at least 1. Use a different `max_slope` to get parts that differ by, say, 2:

```
sage: Partitions(7, max_slope=-1).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
sage: Partitions(15, max_slope=-1).cardinality()
27
```

The number of partitions of n into odd parts equals the number of partitions into distinct parts. Let's test that for n from 10 to 20:

```
sage: test = lambda n: Partitions(n, max_slope=-1).cardinality() == Partitions(n, parts_in=[1,3.
sage: all(test(n) for n in [10..20])
True
```

The number of partitions of n into distinct parts that differ by at least 2 equals the number of partitions into parts that equal 1 or 4 modulo 5; this is one of the Rogers-Ramanujan identities:

```
sage: test = lambda n: Partitions(n, max_slope=-2).cardinality() == Partitions(n, parts_in=([1,6
sage: all(test(n) for n in [10..20])
True
```

Here are some more examples illustrating `min_part`, `max_part`, and `length`:

```
sage: Partitions(5,min_part=2)
Partitions of the integer 5 satisfying constraints min_part=2
sage: Partitions(5,min_part=2).list()
[[5], [3, 2]]
```

```
sage: Partitions(3,max_length=2).list()
[[3], [2, 1]]

sage: Partitions(10, min_part=2, length=3).list()
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]
```

Some examples using the `regular` keyword:

```
sage: Partitions(regular=4)
4-Regular Partitions
sage: Partitions(regular=4, max_length=3)
4-Regular Partitions with max length 3
sage: Partitions(regular=4, max_part=3)
4-Regular 3-Bounded Partitions
sage: Partitions(3, regular=4)
4-Regular Partitions of the integer 3
```

Here are some further examples using various constraints:

```
sage: [x for x in Partitions(4)]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2)]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, max_length=2)]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2, max_length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, max_part=2)]
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, min_part=2)]
[[4], [2, 2]]
sage: [x for x in Partitions(4, outer=[3,1,1])]
[[3, 1], [2, 1, 1]]
sage: [x for x in Partitions(4, outer=[infinity, 1, 1])]
[[4], [3, 1], [2, 1, 1]]
sage: [x for x in Partitions(4, inner=[1,1,1])]
[[2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, max_slope=-1)]
[[4], [3, 1]]
sage: [x for x in Partitions(4, min_slope=-1)]
[[4], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4)]
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4, outer=[
[[6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2]]
```

Note that if you specify `min_part=0`, then it will treat the minimum part as being 1 (see trac ticket #13605):

```
sage: [x for x in Partitions(4, length=3, min_part=0)]
[[2, 1, 1]]
sage: [x for x in Partitions(4, min_length=3, min_part=0)]
[[2, 1, 1], [1, 1, 1, 1]]
```

Except for very special cases, counting is done by brute force iteration through all the partitions. However the iteration itself has a reasonable complexity (see `IntegerListsLex`), which allows for manipulating large partitions:

```
sage: Partitions(1000, max_length=1).list()
[[1000]]
```

In particular, getting the first element is also constant time:

```
sage: Partitions(30, max_part=29).first()
[29, 1]
```

TESTS:

```
sage: TestSuite(Partitions(0)).run()
sage: TestSuite(Partitions(5)).run()
sage: TestSuite(Partitions(5, min_part=2)).run()

sage: repr( Partitions(5, min_part=2) )
'Partitions of the integer 5 satisfying constraints min_part=2'

sage: P = Partitions(5, min_part=2)
sage: P.first().parent()
Partitions...
sage: [2,1] in P
False
sage: [2,2,1] in P
False
sage: [3,2] in P
True

sage: Partitions(5, inner=[2,1], min_length=3).list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partitions(5, inner=Partition([2,2]), min_length=3).list()
[[2, 2, 1]]
sage: Partitions(7, inner=(2, 2), min_length=3).list()
[[4, 2, 1], [3, 3, 1], [3, 2, 2], [3, 2, 1, 1], [2, 2, 2, 1], [2, 2, 1, 1, 1]]
sage: Partitions(5, inner=[2,0,0,0,0,0]).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partitions(6, length=2, max_slope=-1).list()
[[5, 1], [4, 2]]

sage: Partitions(length=2, max_slope=-1).list()
Traceback (most recent call last):
...
ValueError: the size must be specified with any keyword argument

sage: Partitions(max_part = 3)
3-Bounded Partitions
```

Check that trac ticket #14145 has been fixed:

```
sage: 1 in Partitions()
False
```

Check trac ticket #15467:

```
sage: Partitions(5,parts_in=[1,2,3,4], length=4)
Traceback (most recent call last):
...
ValueError: The parameters 'parts_in', 'starting' and 'ending' cannot be combined with anything
sage: Partitions(5,starting=[3,2], length=2)
Traceback (most recent call last):
...
```

```
ValueError: The parameters 'parts_in', 'starting' and 'ending' cannot be combined with anything
sage: Partitions(5,ending=[3,2], length=2)
Traceback (most recent call last):
...
ValueError: The parameters 'parts_in', 'starting' and 'ending' cannot be combined with anything
sage: Partitions(NN, length=2)
Traceback (most recent call last):
...
ValueError: the size must be specified with any keyword argument
sage: Partitions(('la','la','laaaa'), max_part=8)
Traceback (most recent call last):
...
ValueError: n must be an integer or be equal to one of None, NN, NonNegativeIntegers()
```

Check that calling `Partitions` with `outer=a` no longer mutates `a` (trac ticket #16234):

```
sage: a = [4,3,2,1,1,1,1]
sage: for p in Partitions(8, outer=a, min_slope=-1):
....:     print p
[3, 3, 2]
[3, 2, 2, 1]
[3, 2, 1, 1, 1]
[2, 2, 2, 1, 1]
[2, 2, 1, 1, 1, 1]
[2, 1, 1, 1, 1, 1, 1]
sage: a
[4, 3, 2, 1, 1, 1, 1]
```

Check that `inner` and `outer` indeed accept a partition as argument (trac ticket #18423):

```
sage: P = Partitions(5, inner=Partition([2,1]), outer=Partition([3,2])); P
Partitions of the integer 5 satisfying constraints inner=[2, 1], outer=[3, 2]
sage: P.list()
[[3, 2]]
```

Element
alias of `Partition`

global_options(**get_value*, ***set_value*)
Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The `options` to partitions can be accessed as the method `Partitions.global_options` of `Partitions` and related parent classes.

OPTIONS:

- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
  - `English` – use the English convention
  - `French` – use the French convention
- `diagram_str` – (default: `*`) The character used for the cells when printing Ferrers diagrams
- `display` – (default: `list`) Specifies how partitions should be printed
  - `array` – alias for `diagram`
  - `compact` – alias for `compact_low`
  - `compact_high` – compact form of `exp_high`

– `compact_low` – compact form of `exp_low`

– `diagram` – as a Ferrers diagram

– `exp` – alias for `exp_low`

– `exp_high` – in exponential form (highest first)

– `exp_low` – in exponential form (lowest first)

– `ferrers_diagram` – alias for `diagram`

– `list` – displayed as a list

– `young_diagram` – alias for `diagram`

- `latex` – (default: `young_diagram`) Specifies how partitions should be latexed

  – `array` – alias for `diagram`

  – `diagram` – latex as a Ferrers diagram

  – `exp` – alias for `exp_low`

  – `exp_high` – latex as a list in exponential notation (highest first)

  – `exp_low` – as a list latex in exponential notation (lowest first)

  – `ferrers_diagram` – alias for `diagram`

  – `list` – latex as a list

  – `young_diagram` – latex as a Young diagram

- `latex_diagram_str` – (default: `\ast`) The character used for the cells when latexing Ferrers diagrams

- `notation` – alternative name for `convention`

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.global_options(display="exp")
sage: P
1, 2^2, 4
sage: Partitions.global_options(display="exp_high")
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the `display` and `latex` options:

```
sage: Partitions.global_options(display=lambda mu: '<%s>' % ','.join('%s'%m for m in mu._lis
<4,2,2,1>
sage: Partitions.global_options(latex=lambda mu: '\\Diagram{%s}' % ','.join('%s'%m for m in
\Diagram{4,2,2,1}
sage: Partitions.global_options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.global_options(diagram_str="*", convention="french")
sage: print P.ferrers_diagram()
*
```

```
**
**
****
```

Changing the `convention` for partitions also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: print P.ferrers_diagram()
****
**
**
*
sage: T.pp()
  1  2  3
  4  5
sage: Partitions.global_options.reset()
```

See `GlobalOptions` for more features of these options.

subset(**args*, ***kwargs*)

Return `self` if no arguments are given, otherwise raises a `ValueError`.

EXAMPLES:

```
sage: P = Partitions(5, starting=[3,1]); P
Partitions of the integer 5 starting with [3, 1]
sage: P.subset()
Partitions of the integer 5 starting with [3, 1]
sage: P.subset(ending=[3,1])
Traceback (most recent call last):
...
ValueError: Invalid combination of arguments
```

class sage.combinat.partition.**PartitionsGreatestEQ**(*n*, *k*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.combinat.integer_lists.invlex.IntegerListsLex

The class of all (unordered) "restricted" partitions of the integer n having its greatest part equal to the integer k.

EXAMPLES:

```
sage: PartitionsGreatestEQ(10,2)
Partitions of 10 having greatest part equal to 2
sage: PartitionsGreatestEQ(10,2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestEQ(10,2)
False
sage: [2,2,2,2,2] in PartitionsGreatestEQ(10,2)
True
sage: [1]*10 in PartitionsGreatestEQ(10,2)
False
```

```
sage: PartitionsGreatestEQ(10,2).first().parent()
Partitions...
```

Element
alias of Partition

global_options(**get_value*, ***set_value*)
Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method Partitions.global_options of Partitions and related parent classes.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- diagram_str – (default: *) The character used for the cells when printing Ferrers diagrams
- display – (default: list) Specifies how partitions should be printed
  - array – alias for diagram
  - compact – alias for compact_low
  - compact_high – compact form of exp_high
  - compact_low – compact form of exp_low
  - diagram – as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – in exponential form (highest first)
  - exp_low – in exponential form (lowest first)
  - ferrers_diagram – alias for diagram
  - list – displayed as a list
  - young_diagram – alias for diagram
- latex – (default: young_diagram) Specifies how partitions should be latexed
  - array – alias for diagram
  - diagram – latex as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – latex as a list in exponential notation (highest first)
  - exp_low – as a list latex in exponential notation (lowest first)
  - ferrers_diagram – alias for diagram
  - list – latex as a list
  - young_diagram – latex as a Young diagram
- latex_diagram_str – (default: \ast) The character used for the cells when latexing Ferrers diagrams

- notation – alternative name for convention

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.global_options(display="exp")
sage: P
1, 2^2, 4
sage: Partitions.global_options(display="exp_high")
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the display and latex options:

```
sage: Partitions.global_options(display=lambda mu: '<%s>' % ','.join('%s'%m for m in mu._lis
<4,2,2,1>
sage: Partitions.global_options(latex=lambda mu: '\\Diagram{%s}' % ','.join('%s'%m for m in
\Diagram{4,2,2,1}
sage: Partitions.global_options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.global_options(diagram_str="*", convention="french")
sage: print P.ferrers_diagram()
*
**
**
****
```

Changing the convention for partitions also changes the convention option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: print P.ferrers_diagram()
****
**
**
*
sage: T.pp()
  1  2  3
  4  5
sage: Partitions.global_options.reset()
```

See GlobalOptions for more features of these options.

class sage.combinat.partition.**PartitionsGreatestLE**(n, k)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.combinat.integer_lists.invlex.IntegerListsLex

The class of all (unordered) "restricted" partitions of the integer n having parts less than or equal to the integer k.

EXAMPLES:

```
sage: PartitionsGreatestLE(10,2)
Partitions of 10 having parts less than or equal to 2
sage: PartitionsGreatestLE(10,2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestLE(10,2)
False
sage: [2,2,2,2,2] in PartitionsGreatestLE(10,2)
True
sage: PartitionsGreatestLE(10,2).first().parent()
Partitions...
```

Element
alias of Partition

global_options(**get_value*, ***set_value*)
Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method Partitions.global_options of Partitions and related parent classes.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- diagram_str – (default: *) The character used for the cells when printing Ferrers diagrams
- display – (default: list) Specifies how partitions should be printed
  - array – alias for diagram
  - compact – alias for compact_low
  - compact_high – compact form of exp_high
  - compact_low – compact form of exp_low
  - diagram – as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – in exponential form (highest first)
  - exp_low – in exponential form (lowest first)
  - ferrers_diagram – alias for diagram
  - list – displayed as a list
  - young_diagram – alias for diagram
- latex – (default: young_diagram) Specifies how partitions should be latexed
  - array – alias for diagram
  - diagram – latex as a Ferrers diagram

– `exp` – alias for `exp_low`

– `exp_high` – latex as a list in exponential notation (highest first)

– `exp_low` – as a list latex in exponential notation (lowest first)

– `ferrers_diagram` – alias for `diagram`

– `list` – latex as a list

– `young_diagram` – latex as a Young diagram

- `latex_diagram_str` – (default: `\ast`) The character used for the cells when latexing Ferrers diagrams
- `notation` – alternative name for `convention`

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.global_options(display="exp")
sage: P
1, 2^2, 4
sage: Partitions.global_options(display="exp_high")
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the `display` and `latex` options:

```
sage: Partitions.global_options(display=lambda mu: '<%s>' % ','.join('%s'%m for m in mu._lis
<4,2,2,1>
sage: Partitions.global_options(latex=lambda mu: '\\Diagram{%s}' % ','.join('%s'%m for m in
\Diagram{4,2,2,1}
sage: Partitions.global_options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.global_options(diagram_str="*", convention="french")
sage: print P.ferrers_diagram()
*
**
**
****
```

Changing the `convention` for partitions also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: print P.ferrers_diagram()
****
**
**
*
sage: T.pp()
  1  2  3
```

```
  4  5
sage: Partitions.global_options.reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.partition.**PartitionsInBox**(h, w)
Bases: sage.combinat.partition.Partitions

All partitions which fit in an $h \times w$ box.

EXAMPLES:

```
sage: PartitionsInBox(2,2)
Integer partitions which fit in a 2 x 2 box
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
```

list()
Return a list of all the partitions inside a box of height h and width w.

EXAMPLES:

```
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
sage: PartitionsInBox(2,3).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```

TESTS:

Check trac ticket #10890:

```
sage: type(PartitionsInBox(0,0)[0])
<class 'sage.combinat.partition.PartitionsInBox_with_category.element_class'>
```

class sage.combinat.partition.**Partitions_all**
Bases: sage.combinat.partition.Partitions

Class of all partitions.

TESTS:

```
sage: TestSuite( sage.combinat.partition.Partitions_all() ).run()
```

from_beta_numbers(*beta*)
Return a partition corresponding to a sequence of beta numbers.

A sequence of beta numbers is a strictly increasing sequence $0 \leq b_1 < \cdots < b_k$ of non-negative integers. The corresponding partition $\mu = (\mu_k, \ldots, \mu_1)$ is given by $\mu_i = [1, i) \setminus \{b_1, \ldots, b_i\}$. This gives a bijection from the set of partitions with at most k non-zero parts to the set of strictly increasing sequences of non-negative integers of length k.

EXAMPLES:

```
sage: Partitions().from_beta_numbers([0,1,2,4,5,8])
[3, 1, 1]
sage: Partitions().from_beta_numbers([0,2,3,6])
[3, 1, 1]
```

from_core_and_quotient(*core*, *quotient*)
Returns a partition from its core and quotient.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: Partitions().from_core_and_quotient([2,1], [[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
```

TESTS:

```
sage: Partitions().from_core_and_quotient([2,1], [[2,1],[2,3,1],[1,1,1]])
Traceback (most recent call last):
...
ValueError: the quotient [[2, 1], [2, 3, 1], [1, 1, 1]] must be a tuple of partitions
```

We check that trac ticket #11412 is actually fixed:

```
sage: test = lambda x, k: x == Partition(core=x.core(k),
...                                      quotient=x.quotient(k))
sage: all(test(mu,k) for k in range(1,5)
...       for n in range(10) for mu in Partitions(n))
True
sage: test2 = lambda core, mus: (
...       Partition(core=core, quotient=mus).core(mus.level()) == core
...       and
...       Partition(core=core, quotient=mus).quotient(mus.level()) == mus)
sage: all(test2(core,mus)  # long time (5s on sage.math, 2011)
...       for k in range(1,10)
...       for n_core in range(10-k)
...       for core in Partitions(n_core)
...       if core.core(k) == core
...       for n_mus in range(10-k)
...       for mus in PartitionTuples(k,n_mus))
True
```

from_exp(*exp*)

Returns a partition from its list of multiplicities.

EXAMPLES:

```
sage: Partitions().from_exp([2,2,1])
[3, 2, 2, 1, 1]
```

from_frobenius_coordinates(*frobenius_coordinates*)

Returns a partition from a pair of sequences of Frobenius coordinates.

EXAMPLES:

```
sage: Partitions().from_frobenius_coordinates(([],[]))
[]
sage: Partitions().from_frobenius_coordinates(([0],[0]))
[1]
sage: Partitions().from_frobenius_coordinates(([1],[1]))
[2, 1]
sage: Partitions().from_frobenius_coordinates(([6,3,2],[4,1,0]))
[7, 5, 5, 1, 1]
```

from_zero_one(*seq*)

Return a partition from its $0-1$ sequence.

The full $0-1$ sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full $0-1$ sequence starts with infinitely many 0's and ends with infinitely many 1's.

See also:

`Partition.zero_one_sequence()`

INPUT:

The input should be a finite sequence of 0's and 1's. The heading 0's and trailing 1's will be discarded.

EXAMPLES:

```
sage: Partitions().from_zero_one([])
[]
sage: Partitions().from_zero_one([1,0])
[1]
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
```

Heading 0's and trailing 1's are correctly handled:

```
sage: Partitions().from_zero_one([0,0,1,1,1,1,0,1,0,1,1,1])
[5, 4]
```

TESTS:

```
sage: all(Partitions().from_zero_one(mu.zero_one_sequence()) == mu for n in range(10) for mu
True
```

subset(*size=None*, ***kwargs*)

Returns the subset of partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = Partitions()
sage: P.subset(4)
Partitions of the integer 4
```

class sage.combinat.partition.**Partitions_all_bounded**(*k*)

Bases: `sage.combinat.partition.Partitions`

TESTS:

```
sage: TestSuite( sage.combinat.partition.Partitions_all_bounded(3) ).run() # long time
```

class sage.combinat.partition.**Partitions_constraints**(**args*, ***kwds*)

Bases: `sage.combinat.integer_lists.invlex.IntegerListsLex`

For unpickling old constrained `Partitions_constraints` objects created with sage <= 3.4.1. See `Partitions`.

class sage.combinat.partition.**Partitions_ending**(*n*, *ending_partition*)

Bases: `sage.combinat.partition.Partitions`

All partitions with a given ending.

first()

Return the first partition in `self`.

EXAMPLES:

```
sage: Partitions(4, ending=[1,1,1,1]).first()
[4]
```

next(*part*)

Return the next partition after `part` in `self`.

EXAMPLES:

```
sage: Partitions(4, ending=[1,1,1,1]).next(Partition([4]))
[3, 1]
sage: Partitions(4, ending=[1,1,1,1]).next(Partition([1,1,1,1])) is None
True
```

class sage.combinat.partition.**Partitions_n**(*n*)

Bases: sage.combinat.partition.Partitions

Partitions of the integer n.

TESTS:

```
sage: TestSuite( sage.combinat.partition.Partitions_n(0) ).run()
sage: TestSuite( sage.combinat.partition.Partitions_n(0) ).run()
```

cardinality(*algorithm='flint'*)

Return the number of partitions of the specified size.

INPUT:

- `algorithm` - (default: `'flint'`)
  - `'flint'` – use FLINT (currently the fastest)
  - `'bober'` – Use Jonathan Bober's implementation (*very* fast)
  - `'gap'` – use GAP (VERY *slow*)
  - `'pari'` – use PARI. Speed seems the same as GAP until n is in the thousands, in which case PARI is faster.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore the number of partitions p_n is the number of conjugacy classes of the symmetric group on n points.

EXAMPLES:

```
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: Partitions(5).cardinality(algorithm='gap')
7
sage: Partitions(5).cardinality(algorithm='pari')
7
sage: Partitions(5).cardinality(algorithm='bober')
7
sage: number_of_partitions(5, algorithm='flint')
7
```

The input must be a nonnegative integer or a `ValueError` is raised.

```
sage: Partitions(10).cardinality()
42
sage: Partitions(3).cardinality()
3
sage: Partitions(10).cardinality()
42
sage: Partitions(3).cardinality(algorithm='pari')
3
sage: Partitions(10).cardinality(algorithm='pari')
42
```

```
sage: Partitions(40).cardinality()
37338
sage: Partitions(100).cardinality()
190569292
```

A generating function for p_n is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \frac{1}{1-x^k}.$$

We use Sage to verify that the first several coefficients do indeed agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  ## partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [Partitions(k).cardinality() for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

Another consistency test for n up to 500:

```
sage: len([n for n in [1..500] if Partitions(n).cardinality() != Partitions(n).cardinality(a
0
```

REFERENCES:

- Wikipedia article Partition_(number_theory)

first()

Returns the lexicographically first partition of a positive integer n. This is the partition [n].

EXAMPLES:

```
sage: Partitions(4).first()
[4]
```

last()

Return the lexicographically last partition of the positive integer n. This is the all-ones partition.

EXAMPLES:

```
sage: Partitions(4).last()
[1, 1, 1, 1]
```

next(*p*)

Return the lexicographically next partition after the partition p.

EXAMPLES:

```
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

random_element(*measure='uniform'*)

Return a random partitions of n for the specified measure.

INPUT:

- measure – 'uniform' or 'Plancherel' (default: 'uniform')

See also:

- random_element_uniform()
- random_element_plancherel()

EXAMPLES:

```
sage: Partitions(5).random_element() # random
[2, 1, 1, 1]
sage: Partitions(5).random_element(measure='Plancherel') # random
[2, 1, 1, 1]
```

random_element_plancherel()

Return a random partition of n (for the Plancherel measure).

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and Partition.plancherel_measure().

EXAMPLES:

```
sage: Partitions(5).random_element_plancherel()    # random
[2, 1, 1, 1]
sage: Partitions(20).random_element_plancherel()   # random
[9, 3, 3, 2, 2, 1]
```

TESTS:

```
sage: all(Part.random_element_plancherel() in Part
...       for Part in map(Partitions, range(10)))
True
```

Check that trac ticket #18752 is fixed:

```
sage: P = Partitions(5)
sage: la = P.random_element_plancherel()
sage: la.parent() is P
True
```

ALGORITHM:

- insert by Robinson-Schensted a uniform random permutations of n and returns the shape of the resulting tableau. The complexity is $O(n \ln(n))$ which is likely optimal. However, the implementation could be optimized.

AUTHOR:

- Florent Hivert (2009-11-23)

random_element_uniform()

Return a random partition of n with uniform probability.

EXAMPLES:

```
sage: Partitions(5).random_element_uniform()  # random
[2, 1, 1, 1]
sage: Partitions(20).random_element_uniform() # random
[9, 3, 3, 2, 2, 1]
```

TESTS:

```
sage: all(Part.random_element_uniform() in Part
....:     for Part in map(Partitions, range(10)))
True
```

Check that trac ticket #18752 is fixed:

```
sage: P = Partitions(5)
sage: la = P.random_element_uniform()
sage: la.parent() is P
True
```

ALGORITHM:

- It is a python Implementation of RANDPAR, see [nw]. The complexity is unknown, there may be better algorithms.

Todo

Check in Knuth AOCP4.

- There is also certainly a lot of room for optimizations, see comments in the code.

REFERENCES:

AUTHOR:

- Florent Hivert (2009-11-23)

subset(***kwargs*)

Return a subset of `self` with the additional optional arguments.

EXAMPLES:

```
sage: P = Partitions(5); P
Partitions of the integer 5
sage: P.subset(starting=[3,1])
Partitions of the integer 5 starting with [3, 1]
```

class sage.combinat.partition.**Partitions_nk**(*n*, *k*)

Bases: sage.combinat.partition.Partitions

Partitions of the integer n of length equal to k.

TESTS:

```
sage: TestSuite( sage.combinat.partition.Partitions_nk(0,0) ).run()
sage: TestSuite( sage.combinat.partition.Partitions_nk(0,0) ).run()
```

cardinality(*algorithm='hybrid'*)

Return the number of partitions of the specified size with the specified length.

INPUT:

- `algorithm` – (default: `'hybrid'`) the algorithm to compute the cardinality and can be one of the following:
  - `'hybrid'` - use a hybrid algorithm which uses heuristics to reduce the complexity
  - `'gap'` - use GAP

EXAMPLES:

```
sage: v = Partitions(5, length=2).list(); v
[[4, 1], [3, 2]]
sage: len(v)
2
sage: Partitions(5, length=2).cardinality()
2
```

More generally, the number of partitions of n of length 2 is $\left\lfloor \frac{n}{2} \right\rfloor$:

```
sage: all( Partitions(n, length=2).cardinality()
....:      == n // 2 for n in range(10) )
True
```

The number of partitions of n of length 1 is 1 for n positive:

```
sage: all( Partitions(n, length=1).cardinality() == 1
....:      for n in range(1, 10) )
True
```

Further examples:

```
sage: Partitions(5, length=3).cardinality()
2
sage: Partitions(6, length=3).cardinality()
3
sage: Partitions(8, length=4).cardinality()
5
sage: Partitions(8, length=5).cardinality()
3
sage: Partitions(15, length=6).cardinality()
26
sage: Partitions(0, length=0).cardinality()
1
sage: Partitions(0, length=1).cardinality()
0
sage: Partitions(1, length=0).cardinality()
0
sage: Partitions(1, length=4).cardinality()
0
```

TESTS:

We check the hybrid approach gives the same results as GAP:

```
sage: N = [0, 1, 2, 3, 5, 10, 20, 500, 850]
sage: K = [0, 1, 2, 3, 5, 10, 11, 20, 21, 250, 499, 500]
sage: all(Partitions(n,length=k).cardinality() == Partitions(n,length=k).cardinality('gap')
....:     for n in N for k in K)
True
sage: P = Partitions(4562, length=2800)
sage: P.cardinality() == P.cardinality('gap')
True
```

subset (***kwargs*)

Return a subset of `self` with the additional optional arguments.

EXAMPLES:

```
sage: P = Partitions(5, length=2); P
Partitions of the integer 5 of length 2
sage: P.subset(max_part=3)
Partitions of the integer 5 satisfying constraints length=2, max_part=3
```

class sage.combinat.partition.**Partitions_parts_in**(*n*, *parts*)

Bases: sage.combinat.partition.Partitions

Partitions of n with parts in a given set S.

This is invoked indirectly when calling `Partitions(n, parts_in=parts)`, where `parts` is a list of

pairwise distinct integers.

TESTS:

```
sage: TestSuite( sage.combinat.partition.Partitions_parts_in(6, parts=[2,1]) ).run()
```

cardinality()

Return the number of partitions with parts in `self`. Wraps GAP's `NrRestrictedPartitions`.

EXAMPLES:

```
sage: Partitions(15, parts_in=[2,3,7]).cardinality()
5
```

If you can use all parts 1 through n, we'd better get $p(n)$:

```
sage: Partitions(20, parts_in=[1..20]).cardinality() == Partitions(20).cardinality()
True
```

TESTS:

Let's check the consistency of GAP's function and our own algorithm that actually generates the partitions:

```
sage: ps = Partitions(15, parts_in=[1,2,3])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(15, parts_in=[])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(3000, parts_in=[50,100,500,1000])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(10, parts_in=[3,6,9])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(0, parts_in=[1,2])
sage: ps.cardinality() == len(ps.list())
True
```

first()

Return the lexicographically first partition of a positive integer n with the specified parts, or `None` if no such partition exists.

EXAMPLES:

```
sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]
```

last()

Return the lexicographically last partition of the positive integer n with the specified parts, or `None` if no such partition exists.

EXAMPLES:

```
sage: Partitions(15, parts_in=[2,3]).last()
[3, 2, 2, 2, 2, 2, 2]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
sage: Partitions(10, parts_in=[3,6]).last() is None
```

```
True
sage: Partitions(50, parts_in=[11,12,13]).last()
[13, 13, 12, 12]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
```

TESTS:

```
sage: Partitions(6, parts_in=[1..6]).last()
[1, 1, 1, 1, 1, 1]
sage: Partitions(0, parts_in=[]).last()
[]
sage: Partitions(50, parts_in=[11,12]).last() is None
True
```

class sage.combinat.partition.**Partitions_starting**(*n*, *starting_partition*)

Bases: sage.combinat.partition.Partitions

All partitions with a given start.

first()

Return the first partition in self.

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).first()
[2, 1]
```

next(*part*)

Return the next partition after part in self.

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).next(Partition([2,1]))
[1, 1, 1]
```

class sage.combinat.partition.**Partitions_with_constraints**(**args*, ***kwds*)

Bases: sage.combinat.integer_lists.invlex.IntegerListsLex

Partitions which satisfy a set of constraints.

EXAMPLES:

```
sage: P = Partitions(6, inner=[1,1], max_slope=-1)
sage: list(P)
[[5, 1], [4, 2], [3, 2, 1]]
```

TESTS:

```
sage: P = Partitions(6, min_part=2, max_slope=-1)
sage: TestSuite(P).run()
```

Test that trac ticket #15525 is fixed:

```
sage: loads(dumps(P)) == P
True
```

Element

alias of Partition

global_options(**get_value*, ***set_value*)

Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes.

If no parameters are set, then the function returns a copy of the options dictionary.

The `options` to partitions can be accessed as the method `Partitions.global_options` of `Partitions` and related parent classes.

OPTIONS:

- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
  - `English` – use the English convention
  - `French` – use the French convention
- `diagram_str` – (default: `*`) The character used for the cells when printing Ferrers diagrams
- `display` – (default: `list`) Specifies how partitions should be printed
  - `array` – alias for `diagram`
  - `compact` – alias for `compact_low`
  - `compact_high` – compact form of `exp_high`
  - `compact_low` – compact form of `exp_low`
  - `diagram` – as a Ferrers diagram
  - `exp` – alias for `exp_low`
  - `exp_high` – in exponential form (highest first)
  - `exp_low` – in exponential form (lowest first)
  - `ferrers_diagram` – alias for `diagram`
  - `list` – displayed as a list
  - `young_diagram` – alias for `diagram`
- `latex` – (default: `young_diagram`) Specifies how partitions should be latexed
  - `array` – alias for `diagram`
  - `diagram` – latex as a Ferrers diagram
  - `exp` – alias for `exp_low`
  - `exp_high` – latex as a list in exponential notation (highest first)
  - `exp_low` – as a list latex in exponential notation (lowest first)
  - `ferrers_diagram` – alias for `diagram`
  - `list` – latex as a list
  - `young_diagram` – latex as a Young diagram
- `latex_diagram_str` – (default: `\ast`) The character used for the cells when latexing Ferrers diagrams
- `notation` – alternative name for `convention`

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.global_options(display="exp")
sage: P
1, 2^2, 4
```

```
sage: Partitions.global_options(display="exp_high")
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the `display` and `latex` options:

```
sage: Partitions.global_options(display=lambda mu: '<%s>' % ','.join('%s'%m for m in mu._lis
<4,2,2,1>
sage: Partitions.global_options(latex=lambda mu: '\\Diagram{%s}' % ','.join('%s'%m for m in
\Diagram{4,2,2,1}
sage: Partitions.global_options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.global_options(diagram_str="*", convention="french")
sage: print P.ferrers_diagram()
*
**
**
****
```

Changing the `convention` for partitions also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: print P.ferrers_diagram()
****
**
**
*
sage: T.pp()
  1  2  3
  4  5
sage: Partitions.global_options.reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.partition.**RegularPartitions**(*ell*, *is_infinite=False*)

Bases: sage.combinat.partition.Partitions

Base class for ℓ-regular partitions.

Let ℓ be a positive integer. A partition λ is *ℓ-regular* if $m_i < \ell$ for all i, where m_i is the multiplicity of i in λ.

Note: This is conjugate to the notion of *ℓ-restricted* partitions, where the difference between any two parts is at most ℓ.

INPUT:

- `ell` – the integer ℓ
- `is_infinite` – boolean; if the subset of ℓ-regular partitions is infinite

ell()
Return the value ℓ.

EXAMPLES:

```
sage: P = Partitions(regular=2)
sage: P.ell()
2
```

class sage.combinat.partition.**RegularPartitions_all**(*ell*)
Bases: sage.combinat.partition.RegularPartitions

The class of all ℓ-regular partitions.

INPUT:

- ell – the integer ℓ

See also:

RegularPartitions

class sage.combinat.partition.**RegularPartitions_bounded**(*ell*, *k*)
Bases: sage.combinat.partition.RegularPartitions

The class of ℓ-regular k-bounded partitions.

INPUT:

- ell – the integer ℓ
- k – integer; the value k

See also:

RegularPartitions

class sage.combinat.partition.**RegularPartitions_n**(*n*, *ell*)
Bases: sage.combinat.partition.RegularPartitions, sage.combinat.partition.Partitions_n

The class of ℓ-regular partitions of n.

INPUT:

- n – the integer n to partition
- ell – the integer ℓ

See also:

RegularPartitions

cardinality()
Return the cardinality of self.

EXAMPLES:

```
sage: P = Partitions(5, regular=3)
sage: P.cardinality()
5
sage: P = Partitions(5, regular=6)
sage: P.cardinality()
7
sage: P.cardinality() == Partitions(5).cardinality()
True
```

class sage.combinat.partition.**RegularPartitions_truncated**(*ell*, *max_len*)
Bases: sage.combinat.partition.RegularPartitions

The class of ℓ-regular partitions with max length k.

INPUT:

- ell – the integer ℓ
- max_len – integer; the maximum length

See also:

RegularPartitions

max_length()
Return the maximum length of the partitions of self.

EXAMPLES:

```
sage: P = Partitions(regular=4, max_length=3)
sage: P.max_length()
3
```

sage.combinat.partition.**RestrictedPartitions**(*n*, *S*, *k=None*)
This function has been deprecated and will be removed in a future version of Sage; use Partitions with the parts_in keyword. Note, however, that the current implementation of Partitions does not allow the parts_in keyword to be combined with keywords such as max_length; see trac ticket #13072 and trac ticket #12278 for more details. This class should not be removed until this problem has been fixed.

Original docstring follows.

A restricted partition is, like an ordinary partition, an unordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order. The difference is that here the p_i must be elements from the set S, while for ordinary partitions they may be elements from $[1..n]$.

Returns the list of all restricted partitions of the positive integer n into sums with k summands with the summands of the partition coming from the set S. If k is not given all restricted partitions for all k are returned.

Wraps GAP's RestrictedPartitions.

EXAMPLES:

```
sage: from sage.combinat.partition import RestrictedPartitions
sage: RestrictedPartitions(5,[3,2,1])
doctest:...: DeprecationWarning: RestrictedPartitions is deprecated; use Partitions with the par
See http://trac.sagemath.org/13072 for details.
doctest:...: DeprecationWarning: RestrictedPartitions_nsk is deprecated; use Partitions with the
See http://trac.sagemath.org/13072 for details.
Partitions of 5 restricted to the values [1, 2, 3]
sage: RestrictedPartitions(5,[3,2,1]).list()
[[3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: RestrictedPartitions(5,[3,2,1],4)
Partitions of 5 restricted to the values [1, 2, 3] of length 4
sage: RestrictedPartitions(5,[3,2,1],4).list()
[[2, 1, 1, 1]]
```

class sage.combinat.partition.**RestrictedPartitions_nsk**(*n*, *S*, *k=None*)
Bases: sage.combinat.combinat.CombinatorialClass

We are deprecating RestrictedPartitions(), so this class should be deprecated too. See trac ticket #13072.

Element
alias of Partition

cardinality()
Returns the size of self.

Wraps GAP's NrRestrictedPartitions.

EXAMPLES:

```
sage: from sage.combinat.partition import RestrictedPartitions
sage: RestrictedPartitions(8,[1,3,5,7]).cardinality()
doctest:...: DeprecationWarning: RestrictedPartitions is deprecated; use Partitions with the
See http://trac.sagemath.org/13072 for details.
6
sage: RestrictedPartitions(8,[1,3,5,7],2).cardinality()
2
```

global_options(**get_value*, ***set_value*)
Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method Partitions.global_options of Partitions and related parent classes.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- diagram_str – (default: *) The character used for the cells when printing Ferrers diagrams
- display – (default: list) Specifies how partitions should be printed
  - array – alias for diagram
  - compact – alias for compact_low
  - compact_high – compact form of exp_high
  - compact_low – compact form of exp_low
  - diagram – as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – in exponential form (highest first)
  - exp_low – in exponential form (lowest first)
  - ferrers_diagram – alias for diagram
  - list – displayed as a list
  - young_diagram – alias for diagram
- latex – (default: young_diagram) Specifies how partitions should be latexed
  - array – alias for diagram
  - diagram – latex as a Ferrers diagram
  - exp – alias for exp_low
  - exp_high – latex as a list in exponential notation (highest first)

– `exp_low` – as a list latex in exponential notation (lowest first)

– `ferrers_diagram` – alias for `diagram`

– `list` – latex as a list

– `young_diagram` – latex as a Young diagram

- `latex_diagram_str` – (default: `\ast`) The character used for the cells when latexing Ferrers diagrams
- `notation` – alternative name for `convention`

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.global_options(display="exp")
sage: P
1, 2^2, 4
sage: Partitions.global_options(display="exp_high")
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the `display` and `latex` options:

```
sage: Partitions.global_options(display=lambda mu: '<%s>' % ','.join('%s'%m for m in mu._lis
<4,2,2,1>
sage: Partitions.global_options(latex=lambda mu: '\\Diagram{%s}' % ','.join('%s'%m for m in
\Diagram{4,2,2,1}
sage: Partitions.global_options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.global_options(diagram_str="*", convention="french")
sage: print P.ferrers_diagram()
*
**
**
****
```

Changing the `convention` for partitions also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: print P.ferrers_diagram()
****
**
**
*
sage: T.pp()
  1  2  3
  4  5
sage: Partitions.global_options.reset()
```

See GlobalOptions for more features of these options.

list()

Returns the list of all restricted partitions of the positive integer n into sums with k summands with the summands of the partition coming from the set S. If k is not given all restricted partitions for all k are returned.

Wraps GAP's RestrictedPartitions.

EXAMPLES:

```
sage: from sage.combinat.partition import RestrictedPartitions
sage: RestrictedPartitions(8,[1,3,5,7]).list()
doctest:...: DeprecationWarning: RestrictedPartitions is deprecated; use Partitions with the
See http://trac.sagemath.org/13072 for details.
[[7, 1], [5, 3], [5, 1, 1, 1], [3, 3, 1, 1], [3, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1]]
sage: RestrictedPartitions(8,[1,3,5,7],2).list()
[[7, 1], [5, 3]]
```

sage.combinat.partition.**number_of_partitions**(*n*, *algorithm='default'*)

Returns the number of partitions of n with, optionally, at most k parts.

The options of number_of_partitions() are being deprecated trac ticket #13072 in favour of Partitions_n.cardinality() so that number_of_partitions() can become a stripped down version of the fastest algorithm available (currently this is using FLINT).

INPUT:

- n – an integer
- algorithm – (default: 'default') [Will be deprecated except in Partition().cardinality()]
  - 'default' – If k is not None, then use Gap (very slow). If k is None, use FLINT.
  - 'flint' – use FLINT
  - 'bober' – use Jonathan Bober's implementation

EXAMPLES:

```
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: number_of_partitions(5, algorithm='bober')
7
```

The input must be a nonnegative integer or a ValueError is raised.

```
sage: number_of_partitions(-5)
Traceback (most recent call last):
...
ValueError: n (=-5) must be a nonnegative integer

sage: number_of_partitions(10)
42
sage: number_of_partitions(3)
3
sage: number_of_partitions(10)
42
sage: number_of_partitions(40)
37338
sage: number_of_partitions(100)
190569292
```

```
sage: number_of_partitions(100000)
27493510569775696512677516320986352688173429315980054758203125984302147328114964173055050741660
```

A generating function for the number of partitions p_n is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \left(\frac{1}{1-x^k} \right).$$

We use Sage to verify that the first several coefficients do instead agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  ## partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [number_of_partitions(k) for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

sage: number_of_partitions_length(10, 0)
0
sage: number_of_partitions_length(10, 1)
1
sage: number_of_partitions_length(0, 0)
1
sage: number_of_partitions_length(0, 1)
0
```

5.1.143 Partition/Diagram Algebras

class sage.combinat.partition_algebra.**PartitionAlgebraElement_ak**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_bk**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_generic**(*M*, *x*)
Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_pk**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_prk**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_rk**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_sk**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebraElement_tk**(*M*, *x*)
Bases: sage.combinat.partition_algebra.PartitionAlgebraElement_generic

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's `__call__()` method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_ak**(*R*, *k*, *n*, *name=None*)

Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_ak(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_bk**(*R*, *k*, *n*, *name=None*)

Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_bk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_generic**(*R*, *cclass*, *n*, *k*, *name=None*, *prefix=None*)

Bases: sage.combinat.combinatorial_algebra.CombinatorialAlgebra

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(QQ, 3, 1)
sage: s == loads(dumps(s))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_pk**(*R*, *k*, *n*, *name=None*)

Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_pk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_prk**(*R*, *k*, *n*, *name=None*)

Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_prk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_rk**(*R*, *k*, *n*, *name=None*)
Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_rk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_sk**(*R*, *k*, *n*, *name=None*)
Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_sk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_tk**(*R*, *k*, *n*, *name=None*)
Bases: sage.combinat.partition_algebra.PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_tk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

sage.combinat.partition_algebra.**SetPartitionsAk**(*k*)
Returns the combinatorial class of set partitions of type A_k.

EXAMPLES:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}

sage: A3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: A3.random_element()  #random
{{1, 3, -3, -1}, {2, -2}}

sage: A3.cardinality()
203

sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5.cardinality()
52

sage: A2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: A2p5.random_element() #random
{{-1}, {-2}, {3, -3}, {1, 2}}
```

class sage.combinat.partition_algebra.**SetPartitionsAk_k**(*k*)
Bases: sage.combinat.set_partition.SetPartitions_set

TESTS:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3 == loads(dumps(A3))
True
```

Element
alias of SetPartitionsXkElement

class sage.combinat.partition_algebra.**SetPartitionsAkhalf_k**(*k*)
Bases: sage.combinat.set_partition.SetPartitions_set

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

Element
alias of SetPartitionsXkElement

sage.combinat.partition_algebra.**SetPartitionsBk**(*k*)
Returns the combinatorial class of set partitions of type B_k. These are the set partitions where every block has size 2.

EXAMPLES:

```
sage: B3 = SetPartitionsBk(3); B3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2

sage: B3.first() #random
{{2, -2}, {1, -3}, {3, -1}}
sage: B3.last() #random
{{1, 2}, {3, -2}, {-3, -1}}
sage: B3.random_element() #random
{{2, -1}, {1, -3}, {3, -2}}

sage: B3.cardinality()
15

sage: B2p5 = SetPartitionsBk(2.5); B2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and with block size 2

sage: B2p5.first() #random
{{2, -1}, {3, -3}, {1, -2}}
sage: B2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}
sage: B2p5.random_element() #random
{{2, -2}, {3, -3}, {1, -1}}

sage: B2p5.cardinality()
3
```

class sage.combinat.partition_algebra.**SetPartitionsBk_k**(*k*)
Bases: sage.combinat.partition_algebra.SetPartitionsAk_k

TESTS:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
```

```
sage: A3 == loads(dumps(A3))
True
```

cardinality()

Returns the number of set partitions in B_k where k is an integer. This is given by (2k)!! = (2k-1)*(2k-3)*...*5*3*1.

EXAMPLES:

```
sage: SetPartitionsBk(3).cardinality()
15
sage: SetPartitionsBk(2).cardinality()
3
sage: SetPartitionsBk(1).cardinality()
1
sage: SetPartitionsBk(4).cardinality()
105
sage: SetPartitionsBk(5).cardinality()
945
```

class sage.combinat.partition_algebra.**SetPartitionsBkhalf_k**(*k*)

Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()

TESTS:

```
sage: B3p5 = SetPartitionsBk(3.5)
sage: B3p5.cardinality()
15
```

sage.combinat.partition_algebra.**SetPartitionsIk**(*k*)

Returns the combinatorial class of set partitions of type I_k. These are set partitions with a propagating number of less than k. Note that the identity set partition {{1, -1}, ..., {k, -k}} is not in I_k.

EXAMPLES:

```
sage: I3 = SetPartitionsIk(3); I3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number < 3
sage: I3.cardinality()
197

sage: I3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: I3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: I3.random_element() #random
{{-1}, {-3, -2}, {2, 3}, {1}}

sage: I2p5 = SetPartitionsIk(2.5); I2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and propagating numbe
sage: I2p5.cardinality()
50
```

```
sage: I2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: I2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: I2p5.random_element() #random
{{-1}, {-2}, {1, 3, -3}, {2}}
```

class sage.combinat.partition_algebra.**SetPartitionsIk_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsAk_k

TESTS:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3 == loads(dumps(A3))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsIk(2).cardinality()
13
```

class sage.combinat.partition_algebra.**SetPartitionsIkhalf_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsIk(1.5).cardinality()
4
sage: SetPartitionsIk(2.5).cardinality()
50
sage: SetPartitionsIk(3.5).cardinality()
871
```

sage.combinat.partition_algebra.**SetPartitionsPRk**(k)

class sage.combinat.partition_algebra.**SetPartitionsPRk_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsRk_k

TESTS:

```
sage: PR3 = SetPartitionsPRk(3); PR3
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive and negative entry in each bl
sage: PR3 == loads(dumps(PR3))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsPRk(2).cardinality()
6
sage: SetPartitionsPRk(3).cardinality()
20
```

```
sage: SetPartitionsPRk(4).cardinality()
70
sage: SetPartitionsPRk(5).cardinality()
252
```

class sage.combinat.partition_algebra.**SetPartitionsPRkhalf_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsRkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsPRk(2.5).cardinality()
6
sage: SetPartitionsPRk(3.5).cardinality()
20
sage: SetPartitionsPRk(4.5).cardinality()
70
```

sage.combinat.partition_algebra.**SetPartitionsPk**(k)

Returns the combinatorial class of set partitions of type P_k. These are the planar set partitions.

EXAMPLES:

```
sage: P3 = SetPartitionsPk(3); P3
Set partitions of {1, ..., 3, -1, ..., -3} that are planar
sage: P3.cardinality()
132

sage: P3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: P3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: P3.random_element() #random
{{1, 2, -1}, {-3}, {3, -2}}

sage: P2p5 = SetPartitionsPk(2.5); P2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and that are planar
sage: P2p5.cardinality()
42

sage: P2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: P2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: P2p5.random_element() #random
{{1, 2, 3, -3}, {-1, -2}}
```

class sage.combinat.partition_algebra.**SetPartitionsPk_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsAk_k

TESTS:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3 == loads(dumps(A3))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsPk(2).cardinality()
14
sage: SetPartitionsPk(3).cardinality()
132
sage: SetPartitionsPk(4).cardinality()
1430
```

class sage.combinat.partition_algebra.**SetPartitionsPkhalf_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsPk(2.5).cardinality()
42
sage: SetPartitionsPk(1.5).cardinality()
5
```

sage.combinat.partition_algebra.**SetPartitionsRk**(k)

class sage.combinat.partition_algebra.**SetPartitionsRk_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsAk_k

TESTS:

```
sage: R3 = SetPartitionsRk(3); R3
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive and negative entry in each bl
sage: R3 == loads(dumps(R3))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsRk(2).cardinality()
7
sage: SetPartitionsRk(3).cardinality()
34
sage: SetPartitionsRk(4).cardinality()
209
sage: SetPartitionsRk(5).cardinality()
1546
```

class sage.combinat.partition_algebra.**SetPartitionsRkhalf_k**(k)

Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()

TESTS:

```
sage: SetPartitionsRk(2.5).cardinality()
7
sage: SetPartitionsRk(3.5).cardinality()
34
sage: SetPartitionsRk(4.5).cardinality()
209
```

sage.combinat.partition_algebra.**SetPartitionsSk**(*k*)

Returns the combinatorial class of set partitions of type S_k. There is a bijection between these set partitions and the permutations of 1, ..., k.

EXAMPLES:

```
sage: S3 = SetPartitionsSk(3); S3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number 3
sage: S3.cardinality()
6

sage: S3.list()  #random
[{{2, -2}, {3, -3}, {1, -1}},
 {{1, -1}, {2, -3}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}},
 {{1, -2}, {2, -3}, {3, -1}},
 {{1, -3}, {2, -1}, {3, -2}},
 {{1, -3}, {2, -2}, {3, -1}}]
sage: S3.first() #random
{{2, -2}, {3, -3}, {1, -1}}
sage: S3.last() #random
{{1, -3}, {2, -2}, {3, -1}}
sage: S3.random_element() #random
{{1, -3}, {2, -1}, {3, -2}}

sage: S3p5 = SetPartitionsSk(3.5); S3p5
Set partitions of {1, ..., 4, -1, ..., -4} with 4 and -4 in the same block and propagating numbe
sage: S3p5.cardinality()
6

sage: S3p5.list() #random
[{{2, -2}, {3, -3}, {1, -1}, {4, -4}},
 {{2, -3}, {1, -1}, {4, -4}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}, {4, -4}},
 {{2, -3}, {1, -2}, {4, -4}, {3, -1}},
 {{1, -3}, {2, -1}, {4, -4}, {3, -2}},
 {{1, -3}, {2, -2}, {4, -4}, {3, -1}}]
sage: S3p5.first() #random
{{2, -2}, {3, -3}, {1, -1}, {4, -4}}
sage: S3p5.last() #random
{{1, -3}, {2, -2}, {4, -4}, {3, -1}}
sage: S3p5.random_element() #random
{{1, -3}, {2, -2}, {4, -4}, {3, -1}}
```

class sage.combinat.partition_algebra.**SetPartitionsSk_k**(*k*)
Bases: sage.combinat.partition_algebra.SetPartitionsAk_k

TESTS:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3 == loads(dumps(A3))
True
```

cardinality()
Returns k!.

TESTS:

```
sage: SetPartitionsSk(2).cardinality()
2
sage: SetPartitionsSk(3).cardinality()
6
sage: SetPartitionsSk(4).cardinality()
24
sage: SetPartitionsSk(5).cardinality()
120
```

class sage.combinat.partition_algebra.**SetPartitionsSkhalf_k**(*k*)
Bases: sage.combinat.partition_algebra.SetPartitionsAkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()
TESTS:

```
sage: SetPartitionsSk(2.5).cardinality()
2
sage: SetPartitionsSk(3.5).cardinality()
6
sage: SetPartitionsSk(4.5).cardinality()
24

sage: ks = [2.5, 3.5, 4.5, 5.5]
sage: sks = [SetPartitionsSk(k) for k in ks]
sage: all([ sk.cardinality() == len(sk.list()) for sk in sks])
True
```

sage.combinat.partition_algebra.**SetPartitionsTk**(*k*)
Returns the combinatorial class of set partitions of type T_k. These are planar set partitions where every block is of size 2.

EXAMPLES:

```
sage: T3 = SetPartitionsTk(3); T3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2 and that are planar
sage: T3.cardinality()
5

sage: T3.first() #random
{{1, -3}, {2, 3}, {-1, -2}}
```

```
sage: T3.last() #random
{{1, 2}, {3, -1}, {-3, -2}}
sage: T3.random_element() #random
{{1, -3}, {2, 3}, {-1, -2}}

sage: T2p5 = SetPartitionsTk(2.5); T2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and with block size 2
sage: T2p5.cardinality()
2

sage: T2p5.first() #random
{{2, -2}, {3, -3}, {1, -1}}
sage: T2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}
```

class sage.combinat.partition_algebra.**SetPartitionsTk_k**(*k*)
Bases: sage.combinat.partition_algebra.SetPartitionsBk_k

TESTS:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3 == loads(dumps(A3))
True
```

cardinality()
TESTS:

```
sage: SetPartitionsTk(2).cardinality()
2
sage: SetPartitionsTk(3).cardinality()
5
sage: SetPartitionsTk(4).cardinality()
14
sage: SetPartitionsTk(5).cardinality()
42
```

class sage.combinat.partition_algebra.**SetPartitionsTkhalf_k**(*k*)
Bases: sage.combinat.partition_algebra.SetPartitionsBkhalf_k

TESTS:

```
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5 == loads(dumps(A2p5))
True
```

cardinality()
TESTS:

```
sage: SetPartitionsTk(2.5).cardinality()
2
sage: SetPartitionsTk(3.5).cardinality()
5
sage: SetPartitionsTk(4.5).cardinality()
14
```

class sage.combinat.partition_algebra.**SetPartitionsXkElement**(*parent*, *s*)
Bases: sage.combinat.set_partition.SetPartition

An element for the classes of SetPartitionXk where X is some letter.

check()

Check to make sure this is a set partition.

EXAMPLES:

```
sage: A2p5 = SetPartitionsAk(2.5)
sage: x = A2p5.first(); x # random
{{1, 2, 3, -1, -3, -2}}
sage: x.check()
sage: y = A2p5.next(x); y
{{-3, -2, -1, 2, 3}, {1}}
sage: y.check()
```

sage.combinat.partition_algebra.**create_set_partition_function**(*letter*, *k*)

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import create_set_partition_function
sage: create_set_partition_function('A', 3)
Set partitions of {1, ..., 3, -1, ..., -3}
```

sage.combinat.partition_algebra.**identity**(*k*)

Returns the identity set partition 1, -1, ..., k, -k

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.identity(2)
{{2, -2}, {1, -1}}
```

sage.combinat.partition_algebra.**is_planar**(*sp*)

Returns True if the diagram corresponding to the set partition is planar; otherwise, it returns False.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.is_planar( pa.to_set_partition([[1,-2],[2,-1]]))
False
sage: pa.is_planar( pa.to_set_partition([[1,-1],[2,-2]]))
True
```

sage.combinat.partition_algebra.**pair_to_graph**(*sp1*, *sp2*)

Return a graph consisting of the disjoint union of the graphs of set partitions sp1 and sp2 along with edges joining the bottom row (negative numbers) of sp1 to the top row (positive numbers) of sp2.

The vertices of the graph sp1 appear in the result as pairs (k, 1), whereas the vertices of the graph sp2 appear as pairs (k, 2).

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices

sage: g.vertices() #random
[(1, 2), (-1, 1), (-2, 2), (-1, 2), (-2, 1), (2, 1), (2, 2), (1, 1)]
sage: g.edges() #random
[((1, 2), (-1, 1), None),
 ((1, 2), (-2, 2), None),
```

```
 ((-1, 1), (2, 1), None),
 ((-1, 2), (2, 2), None),
 ((-2, 1), (1, 1), None),
 ((-2, 1), (2, 2), None)]
```

Another example which used to be wrong until trac ticket #15958:

```
sage: sp3 = pa.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = pa.to_set_partition([[1], [-1], [2], [-2]])
sage: g = pa.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

sage: g.vertices()
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges()
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None)]
```

sage.combinat.partition_algebra.**propagating_number**(*sp*)

Returns the propagating number of the set partition sp. The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,2],[-2,-1]])
sage: pa.propagating_number(sp1)
2
sage: pa.propagating_number(sp2)
0
```

sage.combinat.partition_algebra.**set_partition_composition**(*sp1*, *sp2*)

Returns a tuple consisting of the composition of the set partitions sp1 and sp2 and the number of components removed from the middle rows of the graph.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: pa.set_partition_composition(sp1, sp2) == (pa.identity(2), 0)
True
```

sage.combinat.partition_algebra.**to_graph**(*sp*)

Returns a graph representing the set partition sp.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: g = pa.to_graph( pa.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices

sage: g.vertices() #random
[1, 2, -2, -1]
sage: g.edges() #random
[(1, -2, None), (2, -1, None)]
```

sage.combinat.partition_algebra.**to_set_partition**(*l*, *k=None*)

Coverts a list of a list of numbers to a set partitions. Each list of numbers in the outer list specifies the numbers

contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of 1, ..., k, -1, ..., -k. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.to_set_partition([[1,-1],[2,-2]]) == pa.identity(2)
True
```

5.1.144 Partition tuples

A `PartitionTuple` is a tuple of partitions. That is, an ordered k-tuple of partitions $\mu = (\mu^{(1)}, \mu^{(2)}, ..., \mu^{(k)})$. If

$$n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|$$

then we say that μ is a k-partition of n.

In representation theory partition tuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups,
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type $G(r, 1, n)$,
- the degenerate cyclotomic Hecke algebras of type $G(r, 1, n)$.

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras, which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to partition tuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

A `PartitionTuple` belongs to `PartitionTuples` and its derived classes. `PartitionTuples` is the parent class for all partitions tuples. Four different classes of tuples of partitions are currently supported:

- `PartitionTuples(level=k,size=n)` are k-tuple of partitions of n.
- `PartitionTuples(level=k)` are k-tuple of partitions.
- `PartitionTuples(size=n)` are tuples of partitions of n.
- `PartitionTuples()` are tuples of partitions.

Note: As with `Partitions`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$.

EXAMPLES:

```
sage: PartitionTuple([[2,2],[1,1],[2]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0, 1)]
```

Note: Many `PartitionTuple` methods take the individual coordinates (k, r, c) as their arguments, here k is the component, r is the row index and c is the column index. If your coordinates are in the form `(k,r,c)` then use Python's *-operator.

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]
```

Warning: In sage, if `mu` is a partition tuple then `mu[k]` most naturally refers to the k-th component of `mu`, so we use the convention of the (k, r, c)-th cell in a partition tuple refers to the cell in component k, row r, and column c. In the literature, the cells of a partition tuple are usually written in the form (r, c, k), where r is the row index, c is the column index, and k is the component index.

AUTHORS:

- Andrew Mathas (2012-06-01): Initial classes.

EXAMPLES:

First is a finite enumerated set and the remaining classes are infinite enumerated sets:

```
sage: PartitionTuples().an_element()
([1, 1, 1, 1], [2, 1, 1], [3, 1], [4])
sage: PartitionTuples(4).an_element()
([], [1], [2], [3])
sage: PartitionTuples(size=5).an_element()
([1], [1], [1], [1], [1])
sage: PartitionTuples(4,5).an_element()
([1], [], [], [4])
sage: PartitionTuples(3,2)[:]
[([2], [], []),
 ([1, 1], [], []),
 ([1], [1], []),
 ([1], [], [1]),
 ([], [2], []),
 ([], [1, 1], []),
 ([], [1], [1]),
 ([], [], [2]),
 ([], [], [1, 1])]
sage: PartitionTuples(2,3).list()
[([3], []),
 ([2, 1], []),
 ([1, 1, 1], []),
 ([2], [1]),
 ([1, 1], [1]),
 ([1], [2]),
 ([1], [1, 1]),
 ([], [3]),
 ([], [2, 1]),
 ([], [1, 1, 1])]
```

One tuples of partitions are naturally in bijection with partitions and, as far as possible, partition tuples attempts to identify one tuples with partitions:

```
sage: Partition([4,3]) == PartitionTuple([[4,3]])
True
sage: Partition([4,3]) == PartitionTuple([4,3])
True
sage: PartitionTuple([4,3])
[4, 3]
sage: Partition([4,3]) in PartitionTuples()
True
```

Partition tuples come equipped with many of the corresponding methods for partitions. For example, it is possible to add and remove cells, to conjugate partition tuples, to work with their diagrams, compare partition tuples in dominance and so:

```
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).pp()
   ****   -   **   ***
   *          **
              *
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).conjugate()
([1, 1, 1], [3, 2], [], [2, 1, 1, 1])
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).conjugate().pp()
   *   ***   -   **
   *   **        *
   *             *
                 *
sage: lam=PartitionTuples(3)([[3,2],[],[1,1,1,1]]); lam
([3, 2], [], [1, 1, 1, 1])

             *
             *
sage: lam.removable_cells()
[(0, 0, 2), (0, 1, 1), (2, 3, 0)]
sage: lam.down_list()
[([2, 2], [], [1, 1, 1, 1]),
 ([3, 1], [], [1, 1, 1, 1]),
 ([3, 2], [], [1, 1, 1])]
sage: lam.addable_cells()
[(0, 0, 3), (0, 1, 2), (0, 2, 0), (1, 0, 0), (2, 0, 1), (2, 4, 0)]
sage: lam.up_list()
```

```
[([4, 2], [], [1, 1, 1, 1]),
 ([3, 3], [], [1, 1, 1, 1]),
 ([3, 2, 1], [], [1, 1, 1, 1]),
 ([3, 2], [1], [1, 1, 1, 1]),
 ([3, 2], [], [2, 1, 1, 1]),
 ([3, 2], [], [1, 1, 1, 1, 1])]
sage: lam.conjugate()
([4], [], [2, 2, 1])
sage: lam.dominates( PartitionTuple([[3],[1],[2,2,1]]) )
False
sage: lam.dominates( PartitionTuple([[3],[2],[1,1,1]]))
True
```

Every partition tuple behaves every much like a tuple of partitions:

```
sage: mu=PartitionTuple([[4,1],[],[2,2,1],[3]])
sage: [ nu for nu in mu ]
[[4, 1], [], [2, 2, 1], [3]]
sage: Set([ type(nu) for nu in mu ])
{<class 'sage.combinat.partition.Partitions_all_with_category.element_class'>}
sage: mu[2][2]
1
sage: mu[3]
[3]
sage: mu.components()
[[4, 1], [], [2, 2, 1], [3]]
sage: mu.components() == [ nu for nu in mu ]
True
sage: mu[0]
[4, 1]
sage: mu[1]
[]
sage: mu[2]
[2, 2, 1]
sage: mu[2][0]
2
sage: mu[2][1]
2
sage: mu.level()
4
sage: len(mu)
4
sage: mu.cells()
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 1, 0), (2, 0, 0), (2, 0, 1), (2, 1, 0), (2, 1, 1),
sage: mu.addable_cells()
[(0, 0, 4), (0, 1, 1), (0, 2, 0), (1, 0, 0), (2, 0, 2), (2, 2, 1), (2, 3, 0), (3, 0, 3), (3, 1, 0)]
sage: mu.removable_cells()
[(0, 0, 3), (0, 1, 0), (2, 1, 1), (2, 2, 0), (3, 0, 2)]
```

Attached to a partition tuple is the corresponding Young, or parabolic, subgroup:

```
sage: mu.young_subgroup()
Permutation Group with generators [(), (12,13), (11,12), (8,9), (6,7), (3,4), (2,3), (1,2)]
sage: mu.young_subgroup_generators()
[1, 2, 3, 6, 8, 11, 12]
```

class sage.combinat.partition_tuple.**PartitionTuple**(*parent*, *mu*)

Bases: sage.combinat.combinat.CombinatorialElement

A tuple of Partition.

A tuple of partition comes equipped with many of methods available to partitions. The level of the PartitionTuple is the length of the tuple.

This is an ordered k-tuple of partitions $\mu = (\mu^{(1)}, \mu^{(2)}, ..., \mu^{(k)})$. If

$$n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|$$

then μ is a k-partition of n.

In representation theory PartitionTuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type $G(r, 1, n)$
- the degenerate cyclotomic Hecke algebras of type $G(r, 1, n)$

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to PartitionTuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

Warning: In the literature, the cells of a partition tuple are usually written in the form (r, c, k), where r is the row index, c is the column index, and k is the component index. In sage, if mu is a partition tuple then mu[k] most naturally refers to the k-th component of mu, so we use the convention of the (k, r, c)-th cell in a partition tuple refers to the cell in component k, row r, and column c.

INPUT:

Anything which can reasonably be interpreted as a tuple of partitions. That is, a list or tuple of partitions or valid input to Partition.

EXAMPLES:

```
sage: mu=PartitionTuple( [[3,2],[2,1],[],[1,1,1,1]] ); mu
([3, 2], [2, 1], [], [1, 1, 1, 1])
sage: nu=PartitionTuple( ([3,2],[2,1],[],[1,1,1,1]) ); nu
([3, 2], [2, 1], [], [1, 1, 1, 1])
sage: mu == nu
True
sage: mu is nu
False
sage: mu in PartitionTuples()
True
sage: mu.parent()
```

```

sage: lam.dominates( PartitionTuple([[3],[1],[2,2,1]]) )
False
sage: lam.dominates( PartitionTuple([[3],[2],[1,1,1]]))
True
```

TESTS:

```
sage: TestSuite( PartitionTuple([4,3,2]) ).run()
sage: TestSuite( PartitionTuple([[4,3,2],[],[],[3,2,1]]) ).run()
```

See also:

- PartitionTuples
- Partitions

Element
alias of Partition

add_cell(k, r, c)
Return the partition tuple obtained by adding a cell in row r, column c, and component k.

This does not change self.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).add_cell(0,0,1)
([2, 1], [4, 3], [2, 1, 1])
```

addable_cells()

Return a list of the removable cells of this partition tuple.

All indices are of the form `(k, r, c)`, where `r` is the row-index, `c` is the column index and `k` is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), (2, 3, 0)]
```

arm_length(*k*, *r*, *c*)

Return the length of the arm of cell `(k, r, c)` in `self`.

INPUT:

- `k` – The component
- `r` – The row
- `c` – The cell

OUTPUT:

- The arm length as an integer

The arm of cell `(k, r, c)` is the number of cells in the `k`-th component which are to the right of the cell in row `r` and column `c`.

EXAMPLES:

```
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,0)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,1)
0
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,2,0)
0
```

cells()

Return the coordinates of the cells of `self`. Coordinates are given as (component index, row index, column index) and are 0 based.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[1],[1,1,1]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 2, 0)]
```

components()

Return a list containing the shape of this partition.

This function exists in order to give a uniform way of iterating over the "components" of partition tuples of level 1 (partitions) and for higher levels.

EXAMPLE:

```
sage: for t in PartitionTuple([[2,1],[3,2],[3]]).components():  print '%s\n' % t.ferrers_dia
...
**
*
```

```
***
**

***

sage: for t in PartitionTuple([3,2]).components(): print '%s\n' % t.ferrers_diagram()
...
***
**
```

conjugate()

Return the conjugate partition tuple of `self`.

The conjugate partition tuple is obtained by reversing the order of the components and then swapping the rows and columns in each component.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[1],[1,1,1]]).conjugate()
([3], [1], [2, 1])
```

contains(*mu*)

Returns `True` if this partition tuple contains μ.

If $\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)})$ and $\mu = (\mu^{(1)}, \ldots, \mu^{(m)})$ are two partition tuples then λ contains μ if $m \leq l$ and $\mu_r^{(i)} \leq \lambda_r^{(i)}$ for $1 \leq i \leq m$ and $r \geq 0$.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).contains( PartitionTuple([[1,1],[2],[2,1]]) )
True
```

content(*k*, *r*, *c*, *multicharge*)

Returns the content of the cell.

Let $m_k =$ `multicharge[k]`, then the content of a cell is $m_k + c - r$.

If the `multicharge` is a list of integers then it simply offsets the values of the contents in each component. On the other hand, if the `multicharge` belongs to $\mathbf{Z}/e\mathbf{Z}$ then the corresponding e-residue is returned (that is, the content mod e).

As with the content method for partitions, the content of a cell does not technically depend on the partition tuple, but this method is included because it is often useful.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [0,0,0])
-1
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [1,0,0])
0
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(2,1,0, [0,0,0])
-1
```

and now we return the 3-residue of a cell:

```
sage: multicharge = [IntegerModRing(3)(c) for c in [0,0,0]]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, multicharge)
2
```

corners()

Returns a list of the removable cells of this partition tuple.

All indice are of the form `(k, r, c)`, where `r` is the row-index, `c` is the column index and `k` is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

diagram()

Return a string for the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram()
   **   ***   *
   *    **    *
             *
sage: print PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram()
   ***   **   -   *
   **    *        *
                  *
                  *
sage: PartitionTuples.global_options(convention="french")
sage: print PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram()
                  *
                  *
   **    *        *
   ***   **   -   *
sage: PartitionTuples.global_options.reset()
```

dominates(*mu*)

Return `True` if the PartitionTuple dominates or equals μ and `False` otherwise.

Given partition tuples $\mu = (\mu^{(1)}, ..., \mu^{(m)})$ and $\nu = (\nu^{(1)}, ..., \nu^{(n)})$ then μ dominates ν if

$$\sum_{k=1}^{l-1} |\mu^{(k)}| + \sum_{r \geq 1} \mu_r^{(l)} \geq \sum_{k=1}^{l-1} |\nu^{(k)}| + \sum_{r \geq 1} \nu_r^{(l)}$$

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: nu=PartitionTuple([[1,1],[1,1],[2,1]])
sage: mu.dominates(mu)
True
sage: mu.dominates(nu)
True
sage: nu.dominates(mu)
False
sage: tau=PartitionTuple([[],[2,1],[]])
sage: tau.dominates([[2,1],[],[]])
False
sage: tau.dominates([[],[],[2,1]])
True
```

down()

Generator (iterator) for the partition tuples that are obtained from `self` by removing a cell.

EXAMPLES:

```
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).down()]
[([], [2, 1], [1, 1]), ([], [3], [1, 1]), ([], [3, 1], [1])]
sage: [mu for mu in PartitionTuple([[],[],[]]).down()]
[]
```

down_list()

Return a list of the partition tuples that can be formed from `self` by removing a cell.

EXAMPLES:

```
sage: PartitionTuple([[],[3,1],[1,1]]).down_list()
[([], [2, 1], [1, 1]), ([], [3], [1, 1]), ([], [3, 1], [1])]
sage: PartitionTuple([[],[],[]]).down_list()
[]
```

ferrers_diagram()

Return a string for the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram()
   **   ***   *
   *    **    *
             *
sage: print PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram()
   ***   **   -   *
   **    *        *
                  *
                  *
sage: PartitionTuples.global_options(convention="french")
sage: print PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram()
                  *
                  *
   **    *        *
   ***   **   -   *
sage: PartitionTuples.global_options.reset()
```

garnir_tableau(**cell*)

Return the Garnir tableau of shape `self` corresponding to the cell `cell`.

If `cell` $= (k, a, c)$ then $(k, a+1, c)$ must belong to the diagram of the `PartitionTuple`. If this is not the case then we return `False`.

Note: The function also sets `g._garnir_cell` equal to `cell` which is used by some other functions.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring.

The Garnir tableau are the "first" non-standard tableaux which arise when you act by simple transpositions. If (k, a, c) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers $1, 2, \ldots, n$ entered in order from left to right along the rows of the diagram up to the cell $(k, a, c-1)$, then along the cells $(k, a+1, 1)$ to $(k, a+1, c)$, then (k, a, c) until the end of row a and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

EXAMPLES:

```
sage: PartitionTuple([[5,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()
     1  2  6  7  8     9 10    13 14 15 16
     3  4  5          11 12    17 18 19
```

```
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()
     1  2  6  7  8    12 13    16 17 18 19
     3  4  5          14 15    20 21 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,1,2)).pp()
     1  2  3  4  5    12 13    16 17 18 19
     6  7 11          14 15    20 21 22
     8  9 10
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,0)).pp()
     1  2  3  4  5    13 14    16 17 18 19
     6  7  8          12 15    20 21 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,1)).pp()
     1  2  3  4  5    12 15    16 17 18 19
     6  7  8          13 14    20 21 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,0,1)).pp()
     1  2  3  4  5    12 13    16 19 20 21
     6  7  8          14 15    17 18 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,1,1)).pp()
Traceback (most recent call last):
...
ValueError: (comp, row+1, col) must be inside the diagram
```

See also:

- top_garnir_tableau()

hook_length(*k*, *r*, *c*)

Return the length of the hook of cell `(k, r, c)` in the partition.

The hook of cell `(k, r, c)` is defined as the cells to the right or below (in the English convention). If your coordinates are in the form `(k,r,c)`, use Python's *-operator.

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.hook_length(*c) for c in mu.cells()]
[2, 1, 2, 1, 3, 1, 1]
```

initial_tableau()

Return the StandardTableauTuple which has the numbers $1, 2, \ldots, n$, where n is the size() of self, entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLE:

```
sage: PartitionTuple([ [2,1],[3,2] ]).initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
```

leg_length(*k*, *r*, *c*)

Return the length of the leg of cell `(k, r, c)` in self.

INPUT:

- k – The component
- r – The row

- c – The cell

OUTPUT:

- The leg length as an integer

The leg of cell (k, r, c) is the number of cells in the k-th component which are below the node in row r and column c.

EXAMPLES:

```
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,0)
2
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,1)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,2,0)
0
```

level()

Return the level of this partition tuple.

The level is the length of the tuple.

EXAMPLES:

```
sage: PartitionTuple([[2,1,1,0],[2,1]]).level()
2
sage: PartitionTuple([[],[],[2,1,1]]).level()
3
```

outside_corners()

Return a list of the removable cells of this partition tuple.

All indices are of the form (k, r, c), where r is the row-index, c is the column index and k is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), (2, 3, 0)]
```

pp()

Pretty prints this partition tuple. See diagram().

EXAMPLES:

```
sage: PartitionTuple([[5,5,2,1],[3,2]]).pp()
*****   ***
*****   **
**
*
```

removable_cells()

Returns a list of the removable cells of this partition tuple.

All indice are of the form (k, r, c), where r is the row-index, c is the column index and k is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
```

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

remove_cell(*k*, *r*, *c*)

Return the partition tuple obtained by removing a cell in row `r`, column `c`, and component `k`.

This does not change `self`.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).remove_cell(0,1,0)
([1], [4, 3], [2, 1, 1])
```

size()

Return the size of a partition tuple.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[],[2,2]]).size()
7
sage: PartitionTuple([[],[],[1],[3,2,1]]).size()
7
```

standard_tableaux()

Return the standard tableau tuples of this shape.

EXAMPLE:

```
sage: PartitionTuple([[],[3,2,2,1],[2,2,1],[3]]).standard_tableaux()
Standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [3])
```

to_exp(*k=0*)

Return a tuple of the multiplicities of the parts of a partition.

Use the optional parameter `k` to get a return list of length at least `k`.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).to_exp()
([2], [0, 1], [1, 1])
sage: PartitionTuple([[1,1],[2,2,2,2],[2,1]]).to_exp()
([2], [0, 4], [1, 1])
```

to_list()

Return `self` as a list of lists.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

TESTS:

```
sage: all(mu==PartitionTuple(mu.to_list()) for mu in PartitionTuples(4,4))
True
```

top_garnir_tableau(*e*, *cell*)

Return the most dominant *standard* tableau which dominates the corresponding Garnir tableau and has the same residue that has shape `self` and is determined by `e` and `cell`.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring. The *top Garnir*

tableaux arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR].

If the Garnir node is `cell=(k,r,c)` and m and M are the entries in the cells `(k,r,c)` and `(k,r+1,c)`, respectively, in the initial tableau then the top `e`-Garnir tableau is obtained by inserting the numbers $m, m+1, \ldots, M$ in order from left to right first in the cells in row `r+1` which are not in the `e`-Garnir belt, then in the cell in rows `r` and `r+1` which are in the Garnir belt and then, finally, in the remaining cells in row `r` which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If `e = 0`, or if there are no `e`-bricks in either row `r` or `r+1`, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,2)).pp()
    1  2  3     9 10 12 13 16
    4  5  6    11 14 15 17
    7  8       18 19 20
               21 22
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,1)).pp()
    1  2  3     9 10 11 12 13
    4  5  6    14 15 16 17
    7  8       18 19 20
               21 22
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(1,0,1)).pp()
    1  2  3     9 12 13 14 15
    4  5  6    10 11 16 17
    7  8       18 19 20
               21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(3,0,1)).pp()
Traceback (most recent call last):
...
ValueError: (comp, row+1, col) must be inside the diagram
```

See also:

- `garnir_tableau()`

REFERENCE:

up()

Generator (iterator) for the partition tuples that are obtained from `self` by adding a cell.

EXAMPLES:

```
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).up()]
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3, 1, 1], [1, 1]),
sage: [mu for mu in PartitionTuple([[],[],[],[]]).up()]
[([1], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

up_list()

Return a list of the partition tuples that can be formed from `self` by adding a cell.

EXAMPLES:

```
sage: PartitionTuple([[],[3,1],[1,1]]).up_list()
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3, 1, 1], [1, 1]),
sage: PartitionTuple([[],[],[],[]]).up_list()
[([1], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

young_subgroup()
Return the corresponding Young, or parabolic, subgroup of the symmetric group.

EXAMPLE:

```
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup()
Permutation Group with generators [(), (8,9), (6,7), (5,6), (4,5), (1,2)]
```

young_subgroup_generators()
Return an indexing set for the generators of the corresponding Young subgroup.

EXAMPLE:

```
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup_generators()
[1, 4, 5, 6, 8]
```

class sage.combinat.partition_tuple.**PartitionTuples**
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

List of all partition tuples.

For more information about partition tuples, see PartitionTuple.

This is a factory class which returns the appropriate parent based on the values of level and size.

INPUT:

- level – The length of the tuple
- size – The total number of cells

TESTS:

```
sage: TestSuite( PartitionTuples() ).run()
sage: TestSuite( PartitionTuples(level=4) ).run()
sage: TestSuite( PartitionTuples(size=6) ).run()
sage: TestSuite( PartitionTuples(level=4, size=5) ).run()

sage: [ [2,1],[],[3] ] in PartitionTuples()
True
sage: ( [2,1],[],[3] ) in PartitionTuples()
True
sage: ( [] ) in PartitionTuples()
True
```

Check that trac ticket #14145 has been fixed:

```
sage: 1 in PartitionTuples()
False
```

Element
alias of PartitionTuple

global_options(**get_value*, ***set_value*)
Sets and displays the global options for elements of the partition, skew partition, and partition tuple classes. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method Partitions.global_options of Partitions and related parent classes.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions

– `English` – use the English convention

– `French` – use the French convention

- `diagram_str` – (default: `*`) The character used for the cells when printing Ferrers diagrams
- `display` – (default: `list`) Specifies how partitions should be printed
  - `array` – alias for `diagram`
  - `compact` – alias for `compact_low`
  - `compact_high` – compact form of `exp_high`
  - `compact_low` – compact form of `exp_low`
  - `diagram` – as a Ferrers diagram
  - `exp` – alias for `exp_low`
  - `exp_high` – in exponential form (highest first)
  - `exp_low` – in exponential form (lowest first)
  - `ferrers_diagram` – alias for `diagram`
  - `list` – displayed as a list
  - `young_diagram` – alias for `diagram`
- `latex` – (default: `young_diagram`) Specifies how partitions should be latexed
  - `array` – alias for `diagram`
  - `diagram` – latex as a Ferrers diagram
  - `exp` – alias for `exp_low`
  - `exp_high` – latex as a list in exponential notation (highest first)
  - `exp_low` – as a list latex in exponential notation (lowest first)
  - `ferrers_diagram` – alias for `diagram`
  - `list` – latex as a list
  - `young_diagram` – latex as a Young diagram
- `latex_diagram_str` – (default: `\ast`) The character used for the cells when latexing Ferrers diagrams
- `notation` – alternative name for `convention`

EXAMPLES:

```
sage: P = Partition([4,2,2,1])
sage: P
[4, 2, 2, 1]
sage: Partitions.global_options(display="exp")
sage: P
1, 2^2, 4
sage: Partitions.global_options(display="exp_high")
sage: P
4, 2^2, 1
```

It is also possible to use user defined functions for the `display` and `latex` options:

```
sage: Partitions.global_options(display=lambda mu: '<%s>' % ','.join('%s'%m for m in mu._lis
<4,2,2,1>
sage: Partitions.global_options(latex=lambda mu: '\\Diagram{%s}' % ','.join('%s'%m for m in
\Diagram{4,2,2,1}
sage: Partitions.global_options(display="diagram", diagram_str="#")
sage: P
####
##
##
#
sage: Partitions.global_options(diagram_str="*", convention="french")
sage: print P.ferrers_diagram()
*
**
**
****
```

Changing the `convention` for partitions also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: print P.ferrers_diagram()
****
**
**
*
sage: T.pp()
  1  2  3
  4  5
sage: Partitions.global_options.reset()
```

See `GlobalOptions` for more features of these options.

level()

Return the level or `None` if it is not defined.

EXAMPLES:

```
sage: PartitionTuples().level() is None
True
sage: PartitionTuples(7).level()
7
```

size()

Return the size or `None` if it is not defined.

EXAMPLES:

```
sage: PartitionTuples().size() is None
True
sage: PartitionTuples(size=7).size()
7
```

class sage.combinat.partition_tuple.**PartitionTuples_all**

Bases: sage.combinat.partition_tuple.PartitionTuples

Class of partition tuples of a arbitrary level and arbitrary sum.

class sage.combinat.partition_tuple.**PartitionTuples_level**(*level*)
Bases: sage.combinat.partition_tuple.PartitionTuples

Class of partition tuples of a fixed level, but summing to an arbitrary integer.

class sage.combinat.partition_tuple.**PartitionTuples_level_size**(*level*, *size*)
Bases: sage.combinat.partition_tuple.PartitionTuples

Class of partition tuples with a fixed level and a fixed size.

cardinality()
Returns the number of `level`-tuples of partitions of size `n`.

Wraps a pari function call.

EXAMPLES:

```
sage: PartitionTuples(2,3).cardinality()
10
sage: PartitionTuples(2,8).cardinality()
185
```

TESTS:

The following calls used to fail (trac ticket #11476):

```
sage: PartitionTuples(17,2).cardinality()
170
sage: PartitionTuples(2,17).cardinality()
8470
sage: PartitionTuples(100,13).cardinality()
1103200201478868 00
sage: PartitionTuples(13,90).cardinality()
915064737412001861523528436 11
```

These answers were checked against Gap4 (the last of which takes an awful long time for gap to compute).

class sage.combinat.partition_tuple.**PartitionTuples_size**(*size*)
Bases: sage.combinat.partition_tuple.PartitionTuples

Class of partition tuples of a fixed size, but arbitrary level.

5.1.145 Number of partitions of an integer

AUTHOR:

- William Stein (2007-07-28): initial version
- Jonathan Bober (2007-07-28): wrote the program `partitions_c.cc` that does all the actual heavy lifting.

sage.combinat.partitions.**ZS1_iterator**(*n*)
A fast iterator for the partitions of `n` (in the decreasing lexicographic order) which returns lists and not objects of type `Partition`.

This is an implementation of the ZS1 algorithm found in [ZS98].

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS1_iterator
sage: it = ZS1_iterator(4)
sage: next(it)
[4]
sage: type(_)
<type 'list'>
```

sage.combinat.partitions.**ZS1_iterator_nk**(*n*, *k*)

An iterator for the partitions of `n` of length at most `k` (in the decreasing lexicographic order) which returns lists and not objects of type `Partition`.

The algorithm is a mild variation on `ZS1_iterator()`; I would not vow for its speed.

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: it = ZS1_iterator_nk(4, 3)
sage: next(it)
[4]
sage: type(_)
<type 'list'>
```

sage.combinat.partitions.**number_of_partitions**(*n*)

Returns the number of partitions of the integer n.

EXAMPLES:

```
sage: from sage.combinat.partitions import number_of_partitions
sage: number_of_partitions(3)
3
sage: number_of_partitions(10)
42
sage: number_of_partitions(40)
37338
sage: number_of_partitions(100)
190569292
sage: number_of_partitions(100000)
2749351056977569651267751632098635268817342931598005475820312598430214732811496417305550507416607
```

TESTS:

```
sage: n = 500 + randint(0,500)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1500 + randint(0,1500)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
```

```
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 100000000 + randint(0,100000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0  # long time (4s on sage.math, 2011)
True
```

Another consistency test for n up to 500:

```
sage: len([n for n in [1..500] if number_of_partitions(n) != Partitions(n).cardinality(algorithm
0
```

sage.combinat.partitions.**run_tests**(*longtest=False*, *forever=False*)

Test Bober's algorithm.

EXAMPLES:

```
sage: from sage.combinat.partitions import run_tests
sage: run_tests(False, False)
Computing p(1)... OK.
...
Done.
```

5.1.146 Perfect matchings

A perfect matching of a set S is a partition into 2-element sets. If S is the set $\{1, ..., n\}$, it is equivalent to fixpoint-free involutions. These simple combinatorial objects appear in different domains such as combinatoric of orthogonal polynomials and of the hyperoctaedral groups (see [MV], [McD] and also [CM]):

AUTHOR:

- Valentin Feray, 2010 : initial version

EXAMPLES:

Create a perfect matching:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
```

Count its crossings, if the ground set is totally ordered:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

List the perfect matchings of a given ground set:

```
sage: PerfectMatchings(4).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]]
```

REFERENCES:

class sage.combinat.perfect_matching.**PerfectMatching**

Bases: sage.structure.element_wrapper.ElementWrapper

Class of perfect matching.

An instance of the class can be created from a list of pairs or from a fixed point-free involution as follows:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]);n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: isinstance(m,PerfectMatching)
True
```

The parent, which is the set of perfect matchings of the ground set, is automatically created:

```
sage: n.parent()
Set of perfect matchings of {1, 2, 3, 4, 5, 6, 7, 8}
```

If the ground set is ordered, one can, for example, ask if the matching is non crossing:

```
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_non_crossing()
True
```

TESTS:

```
sage: m = PerfectMatching([]); m
[]
sage: m.parent()
Set of perfect matchings of {}
```

Weingarten_function(*d*, *other=None*)

Returns the Weingarten function of two pairings.

This function is the value of some integrals over the orthogonal groups O_N. With the convention of [CM], the method returns $Wg^{O(d)}(other, self)$.

EXAMPLES:

```
sage: var('N')
N
sage: m = PerfectMatching([(1,3),(2,4)])
sage: n = PerfectMatching([(1,2),(3,4)])
sage: factor(m.Weingarten_function(N,n))
-1/((N + 2)*(N - 1)*N)
```

conjugate_by_permutation(*p*)

Returns the conjugate of the perfect matching `self` by the permutation `p` of the ground set.

EXAMPLE:

```
sage: m = PerfectMatching([(1,4),(2,6),(3,5)])
sage: m.conjugate_by_permutation(Permutation([4,1,5,6,3,2]))
[(4, 6), (1, 2), (5, 3)]
```

TEST:

```
sage: PerfectMatching([]).conjugate_by_permutation(Permutation([]))
[]
```

crossings()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns the list of the pairs of crossing lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.crossings()
[((1, 3), (2, 8))]
```

TESTS:

```
sage: m = PerfectMatching([]); m.crossings()
[]
```

crossings_iterator()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns an iterator over the pairs of crossing lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: it = n.crossings_iterator();
sage: next(it)
((1, 3), (2, 8))
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

is_non_crossing()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns `True` if the picture obtained this way has no crossings.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_non_crossing()
False
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_non_crossing()
True
```

is_non_nesting()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns `True` if the picture obtained this way has no nestings.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_non_nesting()
False
sage: PerfectMatching([(1, 3), (2, 5), (4, 6)]).is_non_nesting()
True
```

loop_type(*other=None*)

INPUT:

- `other` – a perfect matching of the same set of `self`. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the ordered list of the semi-length of these cycles (considered as a partition)

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: m.loop_type(n)
[2, 1]
```

TESTS:

```
sage: m = PerfectMatching([]); m.loop_type()
[]
```

loops(*other=None*)

INPUT:

- `other` – a perfect matching of the same set of `self`. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the list of these cycles (each cycle is given as a list).

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: m.loops(n)
[['a', 'e', 'c', 'b'], ['d', 'f']]

sage: o = PerfectMatching([(1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([(1, 6), (2, 7), (3, 4), (5, 8)])
sage: o.loops(p)
[[1, 7, 2, 4, 3, 8, 5, 6]]
```

loops_iterator(*other=None*)

INPUT:

- other – a perfect matching of the same set of self. (if the second argument is empty, the method an_element() is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns an iterator for these cycles (each cycle is given as a list).

EXAMPLES:

```
sage: o = PerfectMatching([(1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([(1, 6), (2, 7), (3, 4), (5, 8)])
sage: it = o.loops_iterator(p)
sage: next(it)
[1, 7, 2, 4, 3, 8, 5, 6]
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

nestings()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns the list of the pairs of nesting lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: m = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: m.nestings()
[((1, 6), (3, 5)), ((2, 7), (3, 5))]

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.nestings()
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

TESTS:

```
sage: m = PerfectMatching([]); m.nestings()
[]
```

nestings_iterator()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns an iterator over the pairs of nesting lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: n = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: it = n.nestings_iterator();
sage: next(it)
((1, 6), (3, 5))
sage: next(it)
((2, 7), (3, 5))
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

number_of_crossings()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns the number the pairs of crossing lines.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

number_of_loops(*other=None*)

INPUT:

- `other` – a perfect matching of the same set of `self`. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns their numbers.

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: m.number_of_loops(n)
2
```

number_of_nestings()

INPUT:

A perfect matching on a *totally ordered* ground set.

OUTPUT:

We place the element of a ground set and draw the perfect matching by linking the elements of the same pair in the upper half-plane. This function returns the number the pairs of nesting lines.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_nestings()
3
```

partner(*x*)
Returns the element in the same pair than `x` in the matching `self`.

EXAMPLES:

```
sage: m = PerfectMatching([(-3, 1), (2, 4), (-2, 7)]); m.partner(4)
2
sage: n = PerfectMatching([('c','b'),('d','f'),('e','a')])
sage: n.partner('c')
'b'
```

size()
Returns the size of the perfect matching `self`, i.e. the number of elements in the ground set.

EXAMPLES:

```
sage: m = PerfectMatching([(-3, 1), (2, 4), (-2, 7)]); m.size()
6
```

to_graph()
Returns the graph corresponding to the perfect matching.

OUTPUT:

The realization of `self` as a graph.

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_graph().edges(labels=False)
[(1, 3), (2, 4)]
sage: PerfectMatching([[1,4], [3,2]]).to_graph().edges(labels=False)
[(1, 4), (2, 3)]
sage: PerfectMatching([]).to_graph().edges(labels=False)
[]
```

to_non_crossing_set_partition()
Returns the noncrossing set partition (on half as many elements) corresponding to the perfect matching if the perfect matching is noncrossing, and otherwise gives an error.

OUTPUT:

The realization of `self` as a noncrossing set partition.

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_non_crossing_set_partition()
Traceback (most recent call last):
...
ValueError: matching must be non-crossing
sage: PerfectMatching([[1,4], [3,2]]).to_non_crossing_set_partition()
{{1, 2}}
sage: PerfectMatching([]).to_non_crossing_set_partition()
{}
```

to_permutation()
Returns the permutation corresponding to the perfect matching.

OUTPUT:

The realization of `self` as a permutation.

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_permutation()
[3, 4, 1, 2]
sage: PerfectMatching([[1,4], [3,2]]).to_permutation()
[4, 3, 2, 1]
sage: PerfectMatching([]).to_permutation()
[]
```

class sage.combinat.perfect_matching.**PerfectMatchings**(*objects*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Class of perfect matchings of a ground set. At the creation, the set can be given as any iterable object. If the argument is an integer n, it will be transformed into $[1..n]$:

```
sage: M = PerfectMatchings(6);M
Set of perfect matchings of {1, 2, 3, 4, 5, 6}
sage: PerfectMatchings([-1, -3, 1, 2])
Set of perfect matchings of {1, 2, -3, -1}
```

One can ask for the list, the cardinality or an element of a set of perfect matching:

```
sage: PerfectMatchings(4).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]]
sage: PerfectMatchings(8).cardinality()
105
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: M.an_element()
[('a', 'b'), ('f', 'e'), ('c', 'd')]
sage: all([PerfectMatchings(i).an_element() in PerfectMatchings(i)
...        for i in range(2,11,2)])
True
```

TESTS:

```
sage: PerfectMatchings(5).list()
[]
sage: TestSuite(PerfectMatchings(6)).run()
sage: TestSuite(PerfectMatchings([])).run()
```

Element

alias of PerfectMatching

Weingarten_matrix(*N*)

Returns the Weingarten matrix corresponding to the set of PerfectMatchings self.

It is a useful theoretical tool to compute polynomial integral over the orthogonal group O_N (see [CM]).

EXAMPLES:

```
sage: M = PerfectMatchings(4).Weingarten_matrix(var('N'))
sage: N*(N-1)*(N+2)*M.apply_map(factor)
[N + 1    -1    -1]
[   -1 N + 1    -1]
[   -1    -1 N + 1]
```

an_element()

Returns a random element of self.

EXAMPLES:

```
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: M.an_element()
[('a', 'b'), ('f', 'e'), ('c', 'd')]
sage: all([PerfectMatchings(2*i).an_element() in PerfectMatchings(2*i)
...        for i in range(2,11,2)])
True
```

TESTS:

```
sage: p = PerfectMatchings(13).random_element()
Traceback (most recent call last):
...
ValueError: there is no perfect matching on an odd number of elements
```

cardinality()

Returns the cardinality of the set of perfect matching `self`

This is $1 * 3 * 5 * ... * (2n - 1)$, where $2n$ is the size of the ground set.

EXAMPLES:

```
sage: PerfectMatchings(8).cardinality()
105
```

random_element()

Returns a random element of self.

EXAMPLES:

```
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: M.an_element()
[('a', 'b'), ('f', 'e'), ('c', 'd')]
sage: all([PerfectMatchings(2*i).an_element() in PerfectMatchings(2*i)
...        for i in range(2,11,2)])
True
```

TESTS:

```
sage: p = PerfectMatchings(13).random_element()
Traceback (most recent call last):
...
ValueError: there is no perfect matching on an odd number of elements
```

5.1.147 Permutations

The Permutations module. Use `Permutation?` to get information about the Permutation class, and `Permutations?` to get information about the combinatorial class of permutations.

Warning: This file defined `Permutation` which depends upon `CombinatorialElement` despite it being deprecated (see trac ticket #13742). This is dangerous. In particular, the `Permutation._left_to_right_multiply_on_right()` method (which can be called trough multiplication) disables the input checks (see `Permutation()`). This should not happen. Do not trust the results.

What does this file define ?

The main part of this file consists in the definition of permutation objects, i.e. the `Permutation()` method and the `Permutation` class. Global options for elements of the permutation class can be set through the `PermutationOptions` object.

Below are listed all methods and classes defined in this file.

Methods of Permutations objects

`left_action_product()`	Returns the product of `self` with another permutation, in which the oth
`right_action_product()`	Returns the product of `self` with another permutation, in which `self`
`size()`	Returns the size of the permutation `self`.
`cycle_string()`	Returns the disjoint-cycles representation of `self` as string.
`next()`	Returns the permutation that follows `self` in lexicographic order (in the
`prev()`	Returns the permutation that comes directly before `self` in lexicograph
`to_tableau_by_shape()`	Returns a tableau of shape `shape` with the entries in `self`.
`to_cycles()`	Returns the permutation `self` as a list of disjoint cycles.
`forget_cycles()`	Return `self` under the forget cycle map.
`to_permutation_group_element()`	Returns a `PermutationGroupElement` equal to `self`.
`signature()`	Returns the signature of the permutation `sef`.
`is_even()`	Returns `True` if the permutation `self` is even, and `False` otherwise.
`to_matrix()`	Returns a matrix representing the permutation `self`.
`rank()`	Returns the rank of `self` in lexicographic ordering (on the symmetric g
`to_inversion_vector()`	Returns the inversion vector of a permutation `self`.
`inversions()`	Returns a list of the inversions of permutation `self`.
`show()`	Displays the permutation as a drawing.
`number_of_inversions()`	Returns the number of inversions in the permutation `self`.
`noninversions()`	Returns the `k`-noninversions in the permutation `self`.
`number_of_noninversions()`	Returns the number of `k`-noninversions in the permutation `self`.
`length()`	Returns the Coxeter length of a permutation `self`.
`inverse()`	Returns the inverse of a permutation `self`.
`ishift()`	Returns the `i`-shift of `self`.
`iswitch()`	Returns the `i`-switch of `self`.
`runs()`	Returns a list of the runs in the permutation `self`.
`longest_increasing_subsequence_length()`	Returns the length of the longest increasing subsequences of `self`.
`longest_increasing_subsequences()`	Returns the list of the longest increasing subsequences of `self`.
`cycle_type()`	Returns the cycle type of `self` as a partition of `len(self)`.
`foata_bijection()`	Returns the image of the permutation `self` under the Foata bijection ϕ.
`destandardization()`	Return destandardization of `self` with respect to `weight` and `ordere`
`to_lehmer_code()`	Returns the Lehmer code of the permutation `self`.
`to_lehmer_cocode()`	Returns the Lehmer cocode of `self`.
`reduced_word()`	Returns the reduced word of the permutation `self`.
`reduced_words()`	Returns a list of the reduced words of the permutation `self`.
`reduced_word_lexmin()`	Returns a lexicographically minimal reduced word of a permutation `sel`
`fixed_points()`	Returns a list of the fixed points of the permutation `self`.
`number_of_fixed_points()`	Returns the number of fixed points of the permutation `self`.
`recoils()`	Returns the list of the positions of the recoils of the permutation `self`.
`number_of_recoils()`	Returns the number of recoils of the permutation `self`.
`recoils_composition()`	Returns the composition corresponding to the recoils of `self`.
`descents()`	Returns the list of the descents of the permutation `self`.
`idescents()`	Returns a list of the idescents of `self`.
`idescents_signature()`	Returns the list obtained by mapping each position in `self` to -1 if it is
`number_of_descents()`	Returns the number of descents of the permutation `self`.

Table 5.1 – continued from previous page

number_of_idescents()	Returns the number of idescents of the permutation self.
descents_composition()	Returns the composition corresponding to the descents of self.
descent_polynomial()	Returns the descent polynomial of the permutation self.
major_index()	Returns the major index of the permutation self.
imajor_index()	Returns the inverse major index of the permutation self.
to_major_code()	Returns the major code of the permutation self.
peaks()	Returns a list of the peaks of the permutation self.
number_of_peaks()	Returns the number of peaks of the permutation self.
saliances()	Returns a list of the saliances of the permutation self.
number_of_saliances()	Returns the number of saliances of the permutation self.
bruhat_lequal()	Returns True if self is less or equal to p2 in the Bruhat order.
weak_excedences()	Returns all the numbers self[i] such that self[i] >= i+1.
bruhat_inversions()	Returns the list of inversions of self such that the application of this in
bruhat_inversions_iterator()	Returns an iterator over Bruhat inversions of self.
bruhat_succ()	Returns a list of the permutations covering self in the Bruhat order.
bruhat_succ_iterator()	An iterator for the permutations covering self in the Bruhat order.
bruhat_pred()	Returns a list of the permutations covered by self in the Bruhat order.
bruhat_pred_iterator()	An iterator for the permutations covered by self in the Bruhat order.
bruhat_smaller()	Returns the combinatorial class of permutations smaller than or equal to
bruhat_greater()	Returns the combinatorial class of permutations greater than or equal to
permutohedron_lequal()	Returns True if self is less or equal to p2 in the permutohedron order
permutohedron_succ()	Returns a list of the permutations covering self in the permutohedron o
permutohedron_pred()	Returns a list of the permutations covered by self in the permutohedro
permutohedron_smaller()	Returns a list of permutations smaller than or equal to self in the perm
permutohedron_greater()	Returns a list of permutations greater than or equal to self in the permu
right_permutohedron_interval_iterator()	Returns an iterator over permutations in an interval of the permutohedro
right_permutohedron_interval()	Returns a list of permutations in an interval of the permutohedron order.
has_pattern()	Tests whether the permutation self matches the pattern.
avoids()	Tests whether the permutation self avoids the pattern.
pattern_positions()	Returns the list of positions where the pattern patt appears in self.
reverse()	Returns the permutation obtained by reversing the 1-line notation of sel
complement()	Returns the complement of the permutation which is obtained by replaci
permutation_poset()	Returns the permutation poset of self.
dict()	Returns a dictionary corresponding to the permutation self.
action()	Returns the action of the permutation self on a list.
robinson_schensted()	Returns the pair of standard tableaux obtained by running the Robinson-
left_tableau()	Returns the left standard tableau after performing the RSK algorithm.
right_tableau()	Returns the right standard tableau after performing the RSK algorithm.
increasing_tree()	Returns the increasing tree of self.
increasing_tree_shape()	Returns the shape of the increasing tree of self.
binary_search_tree()	Returns the binary search tree of self.
sylvester_class()	Iterates over the equivalence class of self under sylvester congruence
RS_partition()	Returns the shape of the tableaux obtained by the RSK algorithm.
remove_extra_fixed_points()	Returns the permutation obtained by removing any fixed points at the en
retract_plain()	Returns the plain retract of self to a smaller symmetric group S_m.
retract_direct_product()	Returns the direct-product retract of self to a smaller symmetric group
retract_okounkov_vershik()	Returns the Okounkov-Vershik retract of self to a smaller symmetric g
hyperoctahedral_double_coset_type()	Returns the coset-type of self as a partition.
binary_search_tree_shape()	Returns the shape of the binary search tree of self (a non labelled bina
shifted_concatenation()	Returns the right (or left) shifted concatenation of self with a permutat
shifted_shuffle()	Returns the shifted shuffle of self with a permutation other.

Functions defined in this file

from_major_code()	Returns the permutation corresponding to major code mc.
from_permutation_group_element()	Returns a Permutation give a PermutationGroupElement pge.
from_rank()	Returns the permutation with the specified lexicographic rank.
from_inversion_vector()	Returns the permutation corresponding to inversion vector iv.
from_cycles()	Returns the permutation with given disjoint-cycle representation cycles.
from_lehmer_code()	Returns the permutation with Lehmer code lehmer.
from_reduced_word()	Returns the permutation corresponding to the reduced word rw.
bistochastic_as_sum_of_permutations()	Returns a given bistochastic matrix as a nonnegative linear combination of permutations.
descents_composition_list()	Returns a list of all the permutations in a given descent class (i. e., having a given descents composition).
descents_composition_first()	Returns the smallest element of a descent class.
descents_composition_last()	Returns the largest element of a descent class.
bruhat_lequal()	Returns True if p1 is less or equal to p2 in the Bruhat order.
permutohedron_lequal()	Returns True if p1 is less or equal to p2 in the permutohedron order.
to_standard()	Returns a standard permutation corresponding to the permutation self.

AUTHORS:

- Mike Hansen

- Dan Drake (2008-04-07): allow Permutation() to take lists of tuples
- Sebastien Labbe (2009-03-17): added robinson_schensted_inverse
- Travis Scrimshaw:
  - (2012-08-16): `to_standard()` no longer modifies input
  - (2013-01-19): Removed RSK implementation and moved to `rsk`.
  - (2013-07-13): Removed `CombinatorialClass` and moved permutations to the category framework.
- Darij Grinberg (2013-09-07): added methods; ameliorated trac ticket #14885 by exposing and documenting methods for global-independent multiplication.
- Travis Scrimshaw (2014-02-05): Made `StandardPermutations_n` a finite Weyl group to make it more uniform with `SymmetricGroup`. Added ability to compute the conjugacy classes.

Classes and methods

class sage.combinat.permutation.**Arrangements**

Bases: sage.combinat.permutation.Permutations

An arrangement of a multiset `mset` is an ordered selection without repetitions. It is represented by a list that contains only elements from `mset`, but maybe in a different order.

`Arrangements` returns the combinatorial class of arrangements of the multiset `mset` that contain `k` elements.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Arrangements(mset,2).list()
[[1, 1],
 [1, 2],
 [1, 3],
 [1, 4],
 [1, 5],
 [2, 1],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 1],
 [3, 2],
 [3, 4],
 [3, 5],
 [4, 1],
 [4, 2],
 [4, 3],
 [4, 4],
 [4, 5],
 [5, 1],
 [5, 2],
 [5, 3],
 [5, 4]]
 sage: Arrangements(mset,2).cardinality()
 22
 sage: Arrangements( ["c","a","t"], 2 ).list()
 [['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]
 sage: Arrangements( ["c","a","t"], 3 ).list()
 [['c', 'a', 't'],
  ['c', 't', 'a'],
```

```
['a', 'c', 't'],
['a', 't', 'c'],
['t', 'c', 'a'],
['t', 'a', 'c']]
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: A = Arrangements([1,1,2,3,4,4,5], 2)
sage: A.cardinality()
22
```

class sage.combinat.permutation.**Arrangements_msetk**(*mset*, *k*)

Bases: sage.combinat.permutation.Arrangements, sage.combinat.permutation.Permutations_mset

Arrangements of length k of a multiset M.

class sage.combinat.permutation.**Arrangements_setk**(*s*, *k*)

Bases: sage.combinat.permutation.Arrangements, sage.combinat.permutation.Permutations_setk

Arrangements of length k of a set S.

class sage.combinat.permutation.**CyclicPermutations**(*mset*)

Bases: sage.combinat.permutation.Permutations_mset

Return the class of all cyclic permutations of `mset` in cycle notation. These are the same as necklaces.

INPUT:

- `mset` – A multiset

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
sage: CyclicPermutations([1,1,1]).list()
[[1, 1, 1]]
```

iterator(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list() # indirect doctest
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
 sage: CyclicPermutations([1,1,1]).list()
 [[1, 1, 1]]
 sage: CyclicPermutations([1,1,1]).list(distinct=True)
 [[1, 1, 1], [1, 1, 1]]
```

list(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
```

class sage.combinat.permutation.**CyclicPermutationsOfPartition**(*partition*)

Bases: sage.combinat.permutation.Permutations

Combinations of cyclic permutations of each cell of a given partition.

This is the same as a Cartesian product of necklaces.

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],

```

class Element

Bases: sage.structure.list_clone.ClonableArray

A cyclic permutation of a partition.

check()

Check that self is a valid element.

EXAMPLES:

```
sage: CP = CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]])
sage: elt = CP[0]
sage: elt.check()
```

CyclicPermutationsOfPartition.**iterator**(*distinct=False*)

AUTHORS:

- Robert Miller

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list() # indirect doctest
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],

[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
```

class sage.combinat.permutation.**PatternAvoider**(*parent*, *patterns*)

Bases: sage.combinat.backtrack.GenericBacktracker

EXAMPLES:

```
sage: from sage.combinat.permutation import PatternAvoider
sage: P = Permutations(4)
sage: p = PatternAvoider(P, [[1,2,3]])
sage: loads(dumps(p))
<sage.combinat.permutation.PatternAvoider object at 0x...>
```

class sage.combinat.permutation.**Permutation**(*parent*, *l*, *check_input=True*)

Bases: sage.combinat.combinat.CombinatorialElement

A permutation.

Converts `l` to a permutation on $\{1, 2, \ldots, n\}$.

INPUT:

- `l` – Can be any one of the following:
  - an instance of `Permutation`,
  - list of integers, viewed as one-line permutation notation. The construction checks that you give an acceptable entry. To avoid the check, use the `check_input` option.
  - string, expressing the permutation in cycle notation.
  - list of tuples of integers, expressing the permutation in cycle notation.
  - a `PermutationGroupElement`
  - a pair of two standard tableaux of the same shape. This yields the permutation obtained from the pair using the inverse of the Robinson-Schensted algorithm.
- **`check_input` (boolean) – whether to check that input is correct. Slows** the function down, but ensures that nothing bad happens. This is set to `True` by default.

Warning: Since trac ticket #13742 the input is checked for correctness : it is not accepted unless it actually is a permutation on $\{1, \ldots, n\}$. It means that some `Permutation()` objects cannot be created anymore without setting `check_input = False`, as there is no certainty that its functions can handle them, and this should be fixed in a much better way ASAP (the functions should be rewritten to handle those cases, and new tests be added).

Warning: There are two possible conventions for multiplying permutations, and the one currently enabled in Sage by default is the one which has $(pq)(i) = q(p(i))$ for any permutations $p \in S_n$ and $q \in S_n$ and any $1 \leq i \leq n$. (This equation looks less strange when the action of permutations on numbers is written from the right: then it takes the form $i^{pq} = (i^p)^q$, which is an associativity law). There is an alternative convention, which has $(pq)(i) = p(q(i))$ instead. The conventions can be switched at runtime using `sage.combinat.permutation.Permutations.global_options()`. It is best for code not to rely on this setting being set to a particular standard, but rather use the methods `left_action_product()` and `right_action_product()` for multiplying permutations (these methods don't depend on the setting). See trac ticket #14885 for more details.

Note: The `bruhat*` methods refer to the *strong* Bruhat order. To use the *weak* Bruhat order, look under `permutohedron*`.

EXAMPLES:

```
sage: Permutation([2,1])
[2, 1]
sage: Permutation([2, 1, 4, 5, 3])
[2, 1, 4, 5, 3]
sage: Permutation('(1,2)')
[2, 1]
sage: Permutation('(1,2)(3,4,5)')
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2),(3,4,5)) )
[2, 1, 4, 5, 3]
sage: Permutation( [(1,2),(3,4,5)] )
[2, 1, 4, 5, 3]
```

```
sage: Permutation( ((1,2)) )
[2, 1]
sage: Permutation( (1,2) )
[2, 1]
sage: Permutation( ((1,2),) )
[2, 1]
sage: Permutation( ((1,),) )
[1]
sage: Permutation( (1,) )
[1]
sage: Permutation( () )
[]
sage: Permutation( ((),) )
[]
sage: p = Permutation((1, 2, 5)); p
[2, 5, 3, 4, 1]
sage: type(p)
<class 'sage.combinat.permutation.StandardPermutations_n_with_category.element_class'>
```

Construction from a string in cycle notation:

```
sage: p = Permutation( '(4,5)' ); p
[1, 2, 3, 5, 4]
```

The size of the permutation is the maximum integer appearing; add a 1-cycle to increase this:

```
sage: p2 = Permutation( '(4,5)(10)' ); p2
[1, 2, 3, 5, 4, 6, 7, 8, 9, 10]
sage: len(p); len(p2)
5
10
```

We construct a `Permutation` from a `PermutationGroupElement`:

```
sage: g = PermutationGroupElement([2,1,3])
sage: Permutation(g)
[2, 1, 3]
```

From a pair of tableaux of the same shape. This uses the inverse of the Robinson-Schensted algorithm:

```
sage: p = [[1, 4, 7], [2, 5], [3], [6]]
sage: q = [[1, 2, 5], [3, 6], [4], [7]]
sage: P = Tableau(p)
sage: Q = Tableau(q)
sage: Permutation( (p, q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [p, q] )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( (P, Q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [P, Q] )
[3, 6, 5, 2, 7, 4, 1]
```

TESTS:

```
sage: Permutation([()])
[]
sage: Permutation('()')
[]
sage: Permutation(())
```

```
[]
sage: Permutation( [1] )
[1]
```

From a pair of empty tableaux

```
sage: Permutation( ([], []) )
[]
sage: Permutation( [[], []] )
[]
```

_left_to_right_multiply_on_right(*rp*)

Return the permutation obtained by composing `self` with `rp` in such an order that `self` is applied first and `rp` is applied afterwards.

This is usually denoted by either `self * rp` or `rp * self` depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by $p(i)$, then this should be denoted by `rp * self` in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all p, q and i). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by i^p, then this should be denoted by `self * rp` in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all p, q and i).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.right_action_product(q)
[1, 3, 2]
sage: q.right_action_product(p)
[3, 2, 1]
```

_left_to_right_multiply_on_left(*lp*)

Return the permutation obtained by composing `self` with `lp` in such an order that `lp` is applied first and `self` is applied afterwards.

This is usually denoted by either `self * lp` or `lp * self` depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by $p(i)$, then this should be denoted by `self * lp` in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all p, q and i). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by i^p, then this should be denoted by `lp * self` in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all p, q and i).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.left_action_product(q)
[3, 2, 1]
sage: q.left_action_product(p)
[1, 3, 2]
```

RS_partition()

Return the shape of the tableaux obtained by applying the RSK algorithm to `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).RS_partition()
[2, 1, 1]
```

action(*a*)

Return the action of the permutation `self` on a list `a`.

The action of a permutation $p \in S_n$ on an n-element list $(a_1, a_2, \ldots, a_n)$ is defined to be $(a_{p(1)}, a_{p(2)}, \ldots, a_{p(n)})$.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: a = range(3)
sage: p.action(a)
[1, 0, 2]
sage: b = [1,2,3,4]
sage: p.action(b)
Traceback (most recent call last):
...
ValueError: len(a) must equal len(self)

sage: q = Permutation([2,3,1])
sage: a = range(3)
sage: q.action(a)
[1, 2, 0]
```

avoids(*patt*)

Test whether the permutation `self` avoids the pattern `patt`.

EXAMPLES:

```
sage: Permutation([6,2,5,4,3,1]).avoids([4,2,3,1])
False
sage: Permutation([6,1,2,5,4,3]).avoids([4,2,3,1])
True
sage: Permutation([6,1,2,5,4,3]).avoids([3,4,1,2])
True
```

binary_search_tree(*left_to_right=True*)

Return the binary search tree associated to `self`.

If w is a word, then the binary search tree associated to w is defined as the result of starting with an empty binary tree, and then inserting the letters of w one by one into this tree. Here, the insertion is being done according to the method `binary_search_insert()`, and the word w is being traversed from left to right.

A permutation is regarded as a word (using one-line notation), and thus a binary search tree associated to a permutation is defined.

If the optional keyword variable `left_to_right` is set to `False`, the word w is being traversed from right to left instead.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).binary_search_tree()
1[., 4[3[2[., .], .], .]]
sage: Permutation([4,1,3,2]).binary_search_tree()
4[1[., 3[2[., .], .]], .]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```
sage: Permutation([1,4,3,2]).binary_search_tree(False)
2[1[., .], 3[., 4[., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree(False)
2[1[., .], 3[., 4[., .]]]
```

TESTS:

```
sage: Permutation([]).binary_search_tree()
.
```

binary_search_tree_shape(*left_to_right=True*)

Return the shape of the binary search tree of the permutation (a non labelled binary tree).

EXAMPLES:

```
sage: Permutation([1,4,3,2]).binary_search_tree_shape()
[., [[[., .], .], .]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape()
[[., [[., .], .]], .]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```
sage: Permutation([1,4,3,2]).binary_search_tree_shape(False)
[[., .], [., [., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape(False)
[[., .], [., [., .]]]
```

bruhat_greater()

Returns the combinatorial class of permutations greater than or equal to `self` in the Bruhat order (on the symmetric group containing `self`).

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_greater().list()
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

bruhat_inversions()

Return the list of inversions of `self` such that the application of this inversion to `self` decreases its number of inversions by exactly 1.

Equivalently, it returns the list of pairs (i, j) such that $i < j$, such that $p(i) > p(j)$ and such that there exists no k (strictly) between i and j satisfying $p(i) > p(k) > p(j)$.

EXAMPLES:

```
sage: Permutation([5,2,3,4,1]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: Permutation([6,1,4,5,2,3]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_inversions_iterator()

Return the iterator for the inversions of `self` such that the application of this inversion to `self` decreases its number of inversions by exactly 1.

EXAMPLES:

```
sage: list(Permutation([5,2,3,4,1]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: list(Permutation([6,1,4,5,2,3]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_lequal(*p2*)

Return `True` if `self` is less or equal to `p2` in the Bruhat order.

The Bruhat order (also called strong Bruhat order or Chevalley order) on the symmetric group S_n is the partial order on S_n determined by the following condition: If p is a permutation, and i and j are two indices satisfying $p(i) > p(j)$ and $i < j$ (that is, (i, j) is an inversion of p with $i < j$), then $p \circ (i, j)$ (the permutation obtained by first switching i with j and then applying p) is smaller than p in the Bruhat order.

One can show that a permutation $p \in S_n$ is less or equal to a permutation $q \in S_n$ in the Bruhat order if and only if for every $i \in \{0, 1, \cdots, n\}$ and $j \in \{1, 2, \cdots, n\}$, the number of the elements among $p(1), p(2), \cdots, p(j)$ that are greater than i is $\leq$ to the number of the elements among $q(1), q(2), \cdots, q(j)$ that are greater than i.

This method assumes that `self` and `p2` are permutations of the same integer n.

EXAMPLES:

```
sage: Permutation([2,4,3,1]).bruhat_lequal(Permutation([3,4,2,1]))
True

sage: Permutation([2,1,3]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([3,1,2]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,3,1]).bruhat_lequal(Permutation([1,3,2]))
False
sage: sorted( [len([b for b in Permutations(3) if a.bruhat_lequal(b)])
....:          for a in Permutations(3)] )
[1, 2, 2, 4, 4, 6]

sage: Permutation([]).bruhat_lequal(Permutation([]))
True
```

bruhat_pred()

Return a list of the permutations strictly smaller than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_pred_iterator()

An iterator for the permutations strictly smaller than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_smaller()

Return the combinatorial class of permutations smaller than or equal to `self` in the Bruhat order (on the symmetric group containing `self`).

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

bruhat_succ()

Return a list of the permutations strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

bruhat_succ_iterator()

An iterator for the permutations that are strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

complement()

Return the complement of the permutation `self`.

The complement of a permutation $w \in S_n$ is defined as the permutation in S_n sending each i to $n+1-w(i)$.

EXAMPLES:

```
sage: Permutation([1,2,3]).complement()
[3, 2, 1]
sage: Permutation([1, 3, 2]).complement()
[3, 1, 2]
```

cycle_string (*singletons=False*)

Returns a string of the permutation in cycle notation.

If `singletons=True`, it includes 1-cycles in the string.

EXAMPLES:

```
sage: Permutation([1,2,3]).cycle_string()
'()'
sage: Permutation([2,1,3]).cycle_string()
'(1,2)'
sage: Permutation([2,3,1]).cycle_string()
'(1,2,3)'
sage: Permutation([2,1,3]).cycle_string(singletons=True)
'(1,2)(3)'
```

cycle_tuples (*singletons=True*)

Return the permutation `self` as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If `singletons=False` is given, the list does not contain the singleton cycles.

EXAMPLES:

```
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]

sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
```

The algorithm is of complexity $O(n)$ where n is the size of the given permutation.

TESTS:

```
sage: from sage.combinat.permutation import from_cycles
sage: for n in range(1,6):
....:     for p in Permutations(n):
....:         if from_cycles(n, p.to_cycles()) != p:
....:             print "There is a problem with ",p
....:             break
sage: size = 10000
sage: sample = (Permutations(size).random_element() for i in range(5))
sage: all(from_cycles(size, p.to_cycles()) == p for p in sample)
True
```

Note: there is an alternative implementation called `_to_cycle_set` which could be slightly (10%) faster for some input (typically for permutations of size in the range [100, 10000]). You can run the following benchmarks. For small permutations:

```
sage: for size in range(9): # not tested
....:  print size
....:  lp = Permutations(size).list()
```

```
....:  timeit('[p.to_cycles(False) for p in lp]')
....:  timeit('[p._to_cycles_set(False) for p in lp]')
....:  timeit('[p._to_cycles_list(False) for p in lp]')
....:  timeit('[p._to_cycles_orig(False) for p in lp]')
```

and larger ones:

```
sage: for size in [10, 20, 50, 75, 100, 200, 500, 1000, # not tested
....:       2000, 5000, 10000, 15000, 20000, 30000,
....:       50000, 80000, 100000]:
....:    print(size)
....:    lp = [Permutations(size).random_element() for i in range(20)]
....:    timeit("[p.to_cycles() for p in lp]")
....:    timeit("[p._to_cycles_set() for p in lp]")
....:    timeit("[p._to_cycles_list() for p in lp]")
```

cycle_type()

Return a partition of `len(self)` corresponding to the cycle type of `self`. This is a non-increasing sequence of the cycle lengths of `self`.

EXAMPLES:

```
sage: Permutation([3,1,2,4]).cycle_type()
[3, 1]
```

decreasing_runs(*as_tuple=False*)

Decreasing runs of the permutation.

INPUT:

- `as_tuple` – boolean (default: `False`) choice of output format

OUTPUT:

a list of lists or a tuple of tuples

See also:

`runs()`

EXAMPLES:

```
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: s.decreasing_runs()
[[2], [8, 3], [9, 6, 4], [5, 1], [7]]
sage: s.decreasing_runs(as_tuple=True)
((2,), (8, 3), (9, 6, 4), (5, 1), (7,))
```

descent_polynomial()

Return the descent polynomial of the permutation `self`.

The descent polynomial of a permutation p is the product of all the `z[p[i]]` where `i` ranges over the descents of `p`.

A descent of a permutation `p` is an integer `i` such that `p[i] > p[i+1]`. Here, Python's indexing convention is used, so `p[i]` means $p(i+1)$.

REFERENCES:

EXAMPLES:

```
sage: Permutation([2,1,3]).descent_polynomial()
z1
```

```
sage: Permutation([4,3,2,1]).descent_polynomial()
z1*z2^2*z3^3
```

Todo

This docstring needs to be fixed. First, the definition does not match the implementation (or the examples). Second, this doesn't seem to be defined in [GarStan1984] (the descent monomial in their (7.23) is different).

---

descents (*final_descent=False*)

Return the list of the descents of `self`.

A descent of a permutation `p` is an integer `i` such that `p[i] > p[i+1]`. Here, Python's indexing convention is used, so `p[i]` means $p(i+1)$.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([3,1,2]).descents()
[0]
sage: Permutation([1,4,3,2]).descents()
[1, 2]
sage: Permutation([1,4,3,2]).descents(final_descent=True)
[1, 2, 3]
```

descents_composition()

Return the descent composition of `self`.

The descent composition of a permutation $p \in S_n$ is defined as the composition of n whose descent set equals the descent set of p. Here, the descent set of p is defined as the set of all $i \in \{1, 2, \ldots, n-1\}$ satisfying $p(i) > p(i+1)$ (note that this differs from the output of the `descents()` method, since the latter uses Python's indexing which starts at 0 instead of 1). The descent set of a composition $c = (i_1, i_2, \ldots, i_k)$ is defined as the set $\{i_1, i_1+i_2, i_1+i_2+i_3, \ldots, i_1+i_2+\cdots+i_{k-1}\}$.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).descents_composition()
[2, 2]
sage: Permutation([4,1,6,7,2,3,8,5]).descents_composition()
[1, 3, 3, 1]
sage: Permutation([]).descents_composition()
[]
```

destandardize (*weight*, *ordered_alphabet=None*)

Return destandardization of `self` with respect to `weight` and `ordered_alphabet`.

INPUT:

- `weight` – list or tuple of nonnegative integers that sum to n if `self` is a permutation in S_n.
- `ordered_alphabet` – (default: None) a list or tuple specifying the ordered alphabet the destandardized word is over

OUTPUT: word over the `ordered_alphabet` which standardizes to `self`

Let $weight = (w_1, w_2, \ldots, w_\ell)$. Then this methods looks for an increasing sequence of $1, 2, \ldots, w_1$ and labels all letters in it by 1, then an increasing sequence of $w_1+1, w_1+2, \ldots, w_1+w_2$ and labels all these letters by 2, etc.. If an increasing sequence for the specified `weight` does not exist, an error is

returned. The output is a word `w` over the specified ordered alphabet with evaluation `weight` such that `w.standard_permutation()` is `self`.

EXAMPLES:

```
sage: p = Permutation([1,2,5,3,6,4])
sage: p.destandardize([3,1,2])
word: 113132
sage: p = Permutation([2,1,3])
sage: p.destandardize([2,1])
Traceback (most recent call last):
...
ValueError: Standardization with weight [2, 1] is not possible!
```

TESTS:

```
sage: p = Permutation([4,1,2,3,5,6])
sage: p.destandardize([2,1,3], ordered_alphabet = [1,'a',3])
word: 311a33
sage: p.destandardize([2,1,3], ordered_alphabet = [1,'a'])
Traceback (most recent call last):
...
ValueError: Not enough letters in the alphabet are specified compared to the weight
```

dict()

Returns a dictionary corresponding to the permutation.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: d = p.dict()
sage: d[1]
2
sage: d[2]
1
sage: d[3]
3
```

fixed_points()

Return a list of the fixed points of `self`.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).fixed_points()
[1, 4]
sage: Permutation([1,2,3,4]).fixed_points()
[1, 2, 3, 4]
```

foata_bijection()

Return the image of the permutation `self` under the Foata bijection ϕ.

The bijection shows that maj and inv are equidistributed: if $\phi(P) = Q$, then $\mathrm{maj}(P) = \mathrm{inv}(Q)$.

The Foata bijection ϕ is a bijection on the set of words with no two equal letters. It can be defined by induction on the size of the word: Given a word $w_1 w_2 \cdots w_n$, start with $\phi(w_1) = w_1$. At the i-th step, if $\phi(w_1 w_2 \cdots w_i) = v_1 v_2 \cdots v_i$, we define $\phi(w_1 w_2 \cdots w_i w_{i+1})$ by placing w_{i+1} on the end of the word $v_1 v_2 \cdots v_i$ and breaking the word up into blocks as follows. If $w_{i+1} > v_i$, place a vertical line to the right of each v_k for which $w_{i+1} > v_k$. Otherwise, if $w_{i+1} < v_i$, place a vertical line to the right of each v_k for which $w_{i+1} < v_k$. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute $\phi([1, 4, 2, 5, 3])$, the sequence of words is

- 1,
- $|1|4 \to 14$,
- $|14|2 \to 412$,
- $|4|1|2|5 \to 4125$,
- $|4|125|3 \to 45123$.

So $\phi([1,4,2,5,3]) = [4,5,1,2,3]$.

See section 2 of [FoSc78].

REFERENCES:

EXAMPLES:

```
sage: Permutation([1,2,4,3]).foata_bijection()
[4, 1, 2, 3]
sage: Permutation([2,5,1,3,4]).foata_bijection()
[2, 1, 3, 5, 4]

sage: P = Permutation([2,5,1,3,4])
sage: P.major_index() == P.foata_bijection().number_of_inversions()
True

sage: all( P.major_index() == P.foata_bijection().number_of_inversions()
....:      for P in Permutations(4) )
True
```

The example from [FoSc78]:

```
sage: Permutation([7,4,9,2,6,1,5,8,3]).foata_bijection()
[4, 7, 2, 6, 1, 9, 5, 8, 3]
```

Border cases:

```
sage: Permutation([]).foata_bijection()
[]
sage: Permutation([1]).foata_bijection()
[1]
```

forget_cycles()

Return the image of `self` under the map which forgets cycles.

Consider a permutation σ written in standard cyclic form:

$$\sigma = (a_{1,1}, \ldots, a_{1,k_1})(a_{2,1}, \ldots, a_{2,k_2}) \cdots (a_{m,1}, \ldots, a_{m,k_m}),$$

where $a_{1,1} < a_{2,1} < \cdots < a_{m,1}$ and $a_{j,1} < a_{j,i}$ for all $1 \leq j \leq m$ and $2 \leq i \leq k_j$ where we include cycles of length 1 as well. The image of the forget cycle map ϕ is given by

$$\phi(\sigma) = [a_{1,1}, \ldots, a_{1,k_1}, a_{2,1} \ldots, a_{2,k_2}, \ldots, a_{m,1}, \ldots, a_{m,k_m}],$$

considered as a permutation in 1-line notation.

EXAMPLES:

```
sage: P = Permutations(5)
sage: x = P([1, 5, 3, 4, 2])
sage: x.forget_cycles()
[1, 2, 5, 3, 4]
```

We select all permutations with a cycle composition of $[2,3,1]$ in S_6:

```
sage: P = Permutations(6)
sage: l = [p for p in P if [len(t) for t in p.to_cycles()] == [1,3,2]]
```

Next we apply ϕ and then take the inverse, and then view the results as a poset under the Bruhat order:

```
sage: l = [p.forget_cycles().inverse() for p in l]
sage: B = Poset([l, lambda x,y: x.bruhat_lequal(y)])
sage: R.<q> = QQ[]
sage: sum(q^B.rank_function()(x) for x in B)
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
```

We check the statement in [CC13] that the posets $C_{[1,3,1,1]}$ and $C_{[1,3,2]}$ are isomorphic:

```
sage: l2 = [p for p in P if [len(t) for t in p.to_cycles()] == [1,3,1,1]]
sage: l2 = [p.forget_cycles().inverse() for p in l2]
sage: B2 = Poset([l2, lambda x,y: x.bruhat_lequal(y)])
sage: B.is_isomorphic(B2)
True
```

REFERENCES:

has_pattern(*patt*)

Test whether the permutation `self` contains the pattern `patt`.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).has_pattern([1,3,2])
True
```

hyperoctahedral_double_coset_type()

Return the coset-type of `self` as a partition.

`self` must be a permutation of even size $2n$. The coset-type determines the double class of the permutation, that is its image in $H_n \backslash S_{2n} / H_n$, where H_n is the n-th hyperoctahedral group.

The coset-type is determined as follows. Consider the perfect matching $\{\{1,2\},\{3,4\},\ldots,\{2n-1,2n\}\}$ and its image by `self`, and draw them simultaneously as edges of a graph whose vertices are labeled by $1,2,\ldots,2n$. The coset-type is the ordered sequence of the semi-lengths of the cycles of this graph (see Chapter VII of [Mcd] for more details, particularly Section VII.2).

EXAMPLE:

```
sage: Permutation([3, 4, 6, 1, 5, 7, 2, 8]).hyperoctahedral_double_coset_type()
[3, 1]
sage: all([p.hyperoctahedral_double_coset_type() ==
....:      p.inverse().hyperoctahedral_double_coset_type()
....:       for p in Permutations(4)])
True
sage: Permutation([]).hyperoctahedral_double_coset_type()
[]
sage: Permutation([3,1,2]).hyperoctahedral_double_coset_type()
Traceback (most recent call last):
...
ValueError: [3, 1, 2] is a permutation of odd size and has no coset-type
```

REFERENCES:

idescents(*final_descent=False*)

Return a list of the idescents of `self`, that is the list of the descents of `self`'s inverse.

A descent of a permutation `p` is an integer `i` such that `p[i] > p[i+1]`. Here, Python's indexing convention is used, so `p[i]` means $p(i+1)$.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([2,3,1]).idescents()
[0]
sage: Permutation([1,4,3,2]).idescents()
[1, 2]
sage: Permutation([1,4,3,2]).idescents(final_descent=True)
[1, 2, 3]
```

idescents_signature(*final_descent=False*)

Return the list obtained as follows: Each position in `self` is mapped to -1 if it is an idescent and 1 if it is not an idescent.

See `idescents()` for a definition of idescents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).idescents()
[1, 2]
sage: Permutation([1,4,3,2]).idescents_signature()
[1, -1, -1, 1]
```

imajor_index(*final_descent=False*)

Return the inverse major index of the permutation `self`, which is the major index of the inverse of `self`.

The major index of a permutation p is the sum of the descents of p. Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([2,1,3]).imajor_index()
1
sage: Permutation([3,4,1,2]).imajor_index()
2
sage: Permutation([4,3,2,1]).imajor_index()
6
```

increasing_tree(*compare=<built-in function min>*)

Return the increasing tree associated to `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).increasing_tree()
1[., 2[3[4[., .], .], .]]
sage: Permutation([4,1,3,2]).increasing_tree()
1[4[., .], 2[3[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```
sage: Permutation([2,3,4,1]).increasing_tree(max)
4[3[2[., .], .], 1[., .]]
```

```
sage: Permutation([2,3,1,4]).increasing_tree(max)
4[3[2[., .], 1[., .]], .]
```

increasing_tree_shape(*compare=<built-in function min>*)

Return the shape of the increasing tree associated with the permutation.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).increasing_tree_shape()
[., [[[., .], .], .]]
sage: Permutation([4,1,3,2]).increasing_tree_shape()
[[., .], [[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```
sage: Permutation([2,3,4,1]).increasing_tree_shape(max)
[[[., .], .], [., .]]
sage: Permutation([2,3,1,4]).increasing_tree_shape(max)
[[[., .], [., .]], .]
```

inverse()

Return the inverse of `self`.

EXAMPLES:

```
sage: Permutation([3,8,5,10,9,4,6,1,7,2]).inverse()
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
sage: Permutation([2, 4, 1, 5, 3]).inverse()
[3, 1, 5, 2, 4]
sage: ~Permutation([2, 4, 1, 5, 3])
[3, 1, 5, 2, 4]
```

inversions()

Return a list of the inversions of `self`.

An inversion of a permutation p is a pair (i, j) such that $i < j$ and $p(i) > p(j)$.

EXAMPLES:

```
sage: Permutation([3,2,4,1,5]).inversions()
[(1, 2), (1, 4), (2, 4), (3, 4)]
```

is_even()

Return `True` if the permutation `self` is even and `False` otherwise.

EXAMPLES:

```
sage: Permutation([1,2,3]).is_even()
True
sage: Permutation([2,1,3]).is_even()
False
```

ishift(*i*)

Return the `i`-shift of `self`. If an `i`-shift of `self` can't be performed, then `self` is returned.

An i-shift can be applied when i is not inbetween $i-1$ and $i+1$. The i-shift moves i to the other side, and leaves the relative positions of $i-1$ and $i+1$ in place. All other entries of the permutations are also left in place.

EXAMPLES:

Here, 2 is to the left of both 1 and 3. A 2-shift can be applied which moves the 2 to the right and leaves 1 and 3 in their same relative order:

```
sage: Permutation([2,1,3]).ishift(2)
[1, 3, 2]
```

All entries other than i, $i-1$ and $i+1$ are unchanged:

```
sage: Permutation([2,4,1,3]).ishift(2)
[1, 4, 3, 2]
```

Since 2 is between 1 and 3 in `[1,2,3]`, a 2-shift cannot be applied to `[1,2,3]`

```
sage: Permutation([1,2,3]).ishift(2)
[1, 2, 3]
```

iswitch(*i*)

Return the `i`-switch of `self`. If an `i`-switch of `self` can't be performed, then `self` is returned.

An i-switch can be applied when the subsequence of `self` formed by the entries $i-1$, i and $i+1$ is neither increasing nor decreasing. In this case, this subsequence is reversed (i. e., its leftmost element and its rightmost element switch places), while all other letters of `self` are kept in place.

EXAMPLES:

Here, 2 is to the left of both 1 and 3. A 2-switch can be applied which moves the 2 to the right and switches the relative order between 1 and 3:

```
sage: Permutation([2,1,3]).iswitch(2)
[3, 1, 2]
```

All entries other than $i-1$, i and $i+1$ are unchanged:

```
sage: Permutation([2,4,1,3]).iswitch(2)
[3, 4, 1, 2]
```

Since 2 is between 1 and 3 in `[1,2,3]`, a 2-switch cannot be applied to `[1,2,3]`

```
sage: Permutation([1,2,3]).iswitch(2)
[1, 2, 3]
```

left_action_product(*lp*)

Return the permutation obtained by composing `self` with `lp` in such an order that `lp` is applied first and `self` is applied afterwards.

This is usually denoted by either `self * lp` or `lp * self` depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by $p(i)$, then this should be denoted by `self * lp` in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all p, q and i). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by i^p, then this should be denoted by `lp * self` in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all p, q and i).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.left_action_product(q)
[3, 2, 1]
sage: q.left_action_product(p)
[1, 3, 2]
```

left_tableau()
Return the left standard tableau after performing the RSK algorithm on `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).left_tableau()
[[1, 2], [3], [4]]
```

length()
Return the Coxeter length of `self`.

The length of a permutation p is given by the number of inversions of p.

EXAMPLES:

```
sage: Permutation([5, 1, 3, 4, 2]).length()
6
```

longest_increasing_subsequence_length()
Return the length of the longest increasing subsequences of `self`.

EXAMPLES:

```
sage: Permutation([2,3,1,4]).longest_increasing_subsequence_length()
3
sage: all([i.longest_increasing_subsequence_length() == len(RSK(i)[0][0]) for i in Permutati
True
sage: Permutation([]).longest_increasing_subsequence_length()
0
```

longest_increasing_subsequences()
Return the list of the longest increasing subsequences of `self`.

Note: The algorithm is not optimal.

EXAMPLES:

```
sage: Permutation([2,3,4,1]).longest_increasing_subsequences()
[[2, 3, 4]]
sage: Permutation([5, 7, 1, 2, 6, 4, 3]).longest_increasing_subsequences()
[[1, 2, 6], [1, 2, 4], [1, 2, 3]]
```

major_index(*final_descent=False*)
Return the major index of `self`.

The major index of a permutation p is the sum of the descents of p. Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([2,1,3]).major_index()
1
sage: Permutation([3,4,1,2]).major_index()
2
sage: Permutation([4,3,2,1]).major_index()
6
```

next()
Return the permutation that follows `self` in lexicographic order on the symmetric group containing

`self`. If `self` is the last permutation, then `next` returns `False`.

EXAMPLES:

```
sage: p = Permutation([1, 3, 2])
sage: next(p)
[2, 1, 3]
sage: p = Permutation([4,3,2,1])
sage: next(p)
False
```

TESTS:

```
sage: p = Permutation([])
sage: next(p)
False
```

noninversions(*k*)

Return the list of all `k`-noninversions in `self`.

If k is an integer and $p \in S_n$ is a permutation, then a k-noninversion in p is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a k-noninversion in p can be regarded as a k-element subset of $\{1, 2, \ldots, n\}$ on which p restricts to an increasing map.)

EXAMPLES:

```
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.noninversions(1)
[[3], [2], [4], [1], [5]]
sage: p.noninversions(2)
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
sage: p.noninversions(3)
[[3, 4, 5], [2, 4, 5]]
sage: p.noninversions(4)
[]
sage: p.noninversions(5)
[]
```

TESTS:

```
sage: q = Permutation([])
sage: q.noninversions(1)
[]
```

number_of_descents(*final_descent=False*)

Return the number of descents of `self`.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_descents()
2
sage: Permutation([1,4,3,2]).number_of_descents(final_descent=True)
3
```

number_of_fixed_points()

Return the number of fixed points of `self`.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).number_of_fixed_points()
2
sage: Permutation([1,2,3,4]).number_of_fixed_points()
4
```

number_of_idescents(*final_descent=False*)

Return the number of idescents of `self`.

See `idescents()` for a definition of idescents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_idescents()
2
sage: Permutation([1,4,3,2]).number_of_idescents(final_descent=True)
3
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of a permutation is a pair of elements (i, j) with $i < j$ and $p(i) > p(j)$.

REFERENCES:

- http://mathworld.wolfram.com/PermutationInversion.html

EXAMPLES:

```
sage: Permutation([3, 2, 4, 1, 5]).number_of_inversions()
4
sage: Permutation([1, 2, 6, 4, 7, 3, 5]).number_of_inversions()
6
```

number_of_noninversions(k)

Return the number of `k`-noninversions in `self`.

If k is an integer and $p \in S_n$ is a permutation, then a k-noninversion in p is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a k-noninversion in p can be regarded as a k-element subset of $\{1, 2, \ldots, n\}$ on which p restricts to an increasing map.)

The number of k-noninversions in p has been denoted by $\mathrm{noninv}_k(p)$ in [RSW2011], where conjectures and results regarding this number have been stated.

REFERENCES:

EXAMPLES:

```
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.number_of_noninversions(1)
5
sage: p.number_of_noninversions(2)
6
sage: p.number_of_noninversions(3)
2
sage: p.number_of_noninversions(4)
0
sage: p.number_of_noninversions(5)
0
```

The number of 2-noninversions of a permutation $p \in S_n$ is $\binom{n}{2}$ minus its number of inversions:

```
sage: b = binomial(5, 2)
sage: all( x.number_of_noninversions(2) == b - x.number_of_inversions()
....:      for x in Permutations(5) )
True
```

We also check some corner cases:

```
sage: all( x.number_of_noninversions(1) == 5 for x in Permutations(5) )
True
sage: all( x.number_of_noninversions(0) == 1 for x in Permutations(5) )
True
sage: Permutation([]).number_of_noninversions(1)
0
sage: Permutation([]).number_of_noninversions(0)
1
sage: Permutation([2, 1]).number_of_noninversions(3)
0
```

number_of_peaks()

Return the number of peaks of the permutation `self`.

A peak of a permutation p is an integer i such that $p(i-1) < p(i)$ and $p(i) > p(i+1)$.

EXAMPLES:

```
sage: Permutation([1,3,2,4,5]).number_of_peaks()
1
sage: Permutation([4,1,3,2,6,5]).number_of_peaks()
2
```

number_of_recoils()

Return the number of recoils of the permutation `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_recoils()
2
```

number_of_saliances()

Return the number of saliances of `self`.

A saliance of a permutation p is an integer i such that $p(i) > p(j)$ for all $j > i$.

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).number_of_saliances()
2
sage: Permutation([5,4,3,2,1]).number_of_saliances()
5
```

pattern_positions(*patt*)

Return the list of positions where the pattern `patt` appears in the permutation `self`.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).pattern_positions([1,3,2])
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```

peaks()

Return a list of the peaks of the permutation `self`.

A peak of a permutation p is an integer i such that $p(i-1) < p(i)$ and $p(i) > p(i+1)$.

EXAMPLES:

```
sage: Permutation([1,3,2,4,5]).peaks()
[1]
sage: Permutation([4,1,3,2,6,5]).peaks()
[2, 4]
sage: Permutation([]).peaks()
[]
```

permutation_poset()

Return the permutation poset of `self`.

The permutation poset of a permutation p is the poset with vertices $(i, p(i))$ for $i = 1, 2, \ldots, n$ (where n is the size of p) and order inherited from $\mathbf{Z} \times \mathbf{Z}$.

EXAMPLES:

```
sage: Permutation([3,1,5,4,2]).permutation_poset().cover_relations()
[[(2, 1), (5, 2)],
 [(2, 1), (3, 5)],
 [(2, 1), (4, 4)],
 [(1, 3), (3, 5)],
 [(1, 3), (4, 4)]]
sage: Permutation([]).permutation_poset().cover_relations()
[]
sage: Permutation([1,3,2]).permutation_poset().cover_relations()
[[(1, 1), (2, 3)], [(1, 1), (3, 2)]]
sage: Permutation([1,2]).permutation_poset().cover_relations()
[[(1, 1), (2, 2)]]
sage: P = Permutation([1,5,2,4,3])
sage: P.permutation_poset().greene_shape() == P.RS_partition()    # This should hold for any
True
```

permutohedron_greater(*side='right'*)

Return a list of permutations greater than or equal to `self` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
sage: Permutation([4,2,1,3]).permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

permutohedron_join(*other*, *side='right'*)

Return the join of the permutations `self` and `other` in the right permutohedron order (or, if `side` is set to `'left'`, in the left permutohedron order).

The permutohedron orders (see `permutohedron_lequal()`) are lattices; the join operation refers to this lattice structure. In more elementary terms, the join of two permutations π and ψ in the symmetric group S_n is the permutation in S_n whose set of inversion is the transitive closure of the union of the set of inversions of π with the set of inversions of ψ.

See also:

`permutohedron_lequal()`, `permutohedron_meet()`.

ALGORITHM:

It is enough to construct the join of any two permutations π and ψ in S_n with respect to the right weak order. (The join of π and ψ with respect to the left weak order is the inverse of the join of π^{-1} and ψ^{-1} with respect to the right weak order.) Start with an empty list l (denoted `xs` in the actual code). For $i = 1, 2, \ldots, n$ (in this order), we insert i into this list in the rightmost possible position such that any letter in $\{1, 2, ..., i-1\}$ which appears further right than i in either π or ψ (or both) must appear further right than i in the resulting list. After all numbers are inserted, we are left with a list which is precisely the join of π and ψ (in one-line notation). This algorithm is due to Markowsky, [Mark94] (Theorem 1 (a)).

REFERENCES:

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q)
[3, 1, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p)
[3, 2, 1]

sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_join(q)
[4, 3, 2, 1]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_join(r)
[3, 2, 4, 1]
sage: q.permutohedron_join(r)
[4, 3, 2, 1]
sage: s = Permutation([1,4,2,3])
sage: s.permutohedron_join(r)
[4, 3, 1, 2]
```

The universal property of the join operation is satisfied:

```
sage: def test_uni_join(p, q):
....:     j = p.permutohedron_join(q)
....:     if not p.permutohedron_lequal(j):
....:         return False
....:     if not q.permutohedron_lequal(j):
....:         return False
....:     for r in p.permutohedron_greater():
....:         if q.permutohedron_lequal(r) and not j.permutohedron_lequal(r):
....:             return False
....:     return True
sage: all( test_uni_join(p, q) for p in Permutations(3) for q in Permutations(3) )
True
sage: test_uni_join(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3, 1, 2, 5, 4, 6,
True
```

Border cases:

```
sage: p = Permutation([])
sage: p.permutohedron_join(p)
[]
```

```
sage: p = Permutation([1])
sage: p.permutohedron_join(p)
[1]
```

The left permutohedron:

sage: p = Permutation([3,1,2]) sage: q = Permutation([1,3,2]) sage: p.permutohedron_join(q, side="left") [3, 2, 1] sage: r = Permutation([2,1,3]) sage: r.permutohedron_join(p, side="left") [3, 1, 2]

permutohedron_lequal(*p2*, *side='right'*)

Return `True` if `self` is less or equal to `p2` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

For every nonnegative integer n, the right (resp. left) permutohedron order (also called the right (resp. left) weak order, or the right (resp. left) weak Bruhat order) is a partial order on the symmetric group S_n. It can be defined in various ways, including the following ones:

- Two permutations u and v in S_n satisfy $u \leq v$ in the right (resp. left) permutohedron order if and only if the (Coxeter) length of the permutation $v^{-1} \circ u$ (resp. of the permutation $u \circ v^{-1}$) equals the length of v minus the length of u. Here, $p \circ q$ means the permutation obtained by applying q first and then p. (Recall that the Coxeter length of a permutation is its number of inversions.)
- Two permutations u and v in S_n satisfy $u \leq v$ in the right (resp. left) permutohedron order if and only if every pair (i, j) of elements of $\{1, 2, \cdots, n\}$ such that $i < j$ and $u^{-1}(i) > u^{-1}(j)$ (resp. $u(i) > u(j)$) also satisfies $v^{-1}(i) > v^{-1}(j)$ (resp. $v(i) > v(j)$).
- A permutation $v \in S_n$ covers a permutation $u \in S_n$ in the right (resp. left) permutohedron order if and only if we have $v = u \circ (i, i+1)$ (resp. $v = (i, i+1) \circ u$) for some $i \in \{1, 2, \cdots, n-1\}$ satisfying $u(i) < u(i+1)$ (resp. $u^{-1}(i) < u^{-1}(i+1)$). Here, again, $p \circ q$ means the permutation obtained by applying q first and then p.

The right and the left permutohedron order are mutually isomorphic, with the isomorphism being the map sending every permutation to its inverse. Each of these orders endows the symmetric group S_n with the structure of a graded poset (the rank function being the Coxeter length).

Warning: The permutohedron order is not to be mistaken for the strong Bruhat order (`bruhat_lequal()`), despite both orders being occasionally referred to as the Bruhat order.

EXAMPLES:

```
sage: p = Permutation([3,2,1,4])
sage: p.permutohedron_lequal(Permutation([4,2,1,3]))
False
sage: p.permutohedron_lequal(Permutation([4,2,1,3]), side='left')
True
sage: p.permutohedron_lequal(p)
True

sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([3,1,2]))
False
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,1,3]))
False
```

```
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,3,1]))
False
sage: Permutation([2,3,1]).permutohedron_lequal(Permutation([1,3,2]))
False
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]), side='left')
False
sage: sorted( [len([b for b in Permutations(3) if a.permutohedron_lequal(b)])
....:          for a in Permutations(3)] )
[1, 2, 2, 3, 3, 6]
sage: sorted( [len([b for b in Permutations(3) if a.permutohedron_lequal(b, side="left")])
....:          for a in Permutations(3)] )
[1, 2, 2, 3, 3, 6]

sage: Permutation([]).permutohedron_lequal(Permutation([]))
True
```

permutohedron_meet(*other*, *side='right'*)

Return the meet of the permutations `self` and `other` in the right permutohedron order (or, if `side` is set to `'left'`, in the left permutohedron order).

The permutohedron orders (see `permutohedron_lequal()`) are lattices; the meet operation refers to this lattice structure. It is connected to the join operation by the following simple symmetry property: If π and ψ are two permutations π and ψ in the symmetric group S_n, and if w_0 denotes the permutation $(n, n-1, \ldots, 1) \in S_n$, then

$$\pi \wedge \psi = w_0 \circ ((w_0 \circ \pi) \vee (w_0 \circ \psi)) = ((\pi \circ w_0) \vee (\psi \circ w_0)) \circ w_0$$

and

$$\pi \vee \psi = w_0 \circ ((w_0 \circ \pi) \wedge (w_0 \circ \psi)) = ((\pi \circ w_0) \wedge (\psi \circ w_0)) \circ w_0,$$

where $\wedge$ means meet and $\vee$ means join.

See also:

`permutohedron_lequal()`, `permutohedron_join()`.

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q)
[1, 3, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p)
[1, 2, 3]

sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_meet(q)
[2, 1, 3, 4]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_meet(r)
[3, 1, 2, 4]
sage: q.permutohedron_meet(r)
[1, 2, 3, 4]
sage: s = Permutation([1,4,2,3])
```

```
sage: s.permutohedron_meet(r)
[1, 2, 3, 4]
```

The universal property of the meet operation is satisfied:

```
sage: def test_uni_meet(p, q):
....:     m = p.permutohedron_meet(q)
....:     if not m.permutohedron_lequal(p):
....:         return False
....:     if not m.permutohedron_lequal(q):
....:         return False
....:     for r in p.permutohedron_smaller():
....:         if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
....:             return False
....:     return True
sage: all( test_uni_meet(p, q) for p in Permutations(3) for q in Permutations(3) )
True
sage: test_uni_meet(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3, 1, 2, 5, 4, 6,
True
```

Border cases:

```
sage: p = Permutation([])
sage: p.permutohedron_meet(p)
[]
sage: p = Permutation([1])
sage: p.permutohedron_meet(p)
[1]
```

The left permutohedron:

sage: p = Permutation([3,1,2]) sage: q = Permutation([1,3,2]) sage: p.permutohedron_meet(q, side="left") [1, 2, 3] sage: r = Permutation([2,1,3]) sage: r.permutohedron_meet(p, side="left") [2, 1, 3]

permutohedron_pred(*side='right'*)

Return a list of the permutations strictly smaller than `self` in the permutohedron order such that there is no permutation between any of those and `self`.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
sage: p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

permutohedron_smaller(*side='right'*)

Return a list of permutations smaller than or equal to `self` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]

sage: Permutation([4,2,1,3]).permutohedron_smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

permutohedron_succ(*side='right'*)

Return a list of the permutations strictly greater than `self` in the permutohedron order such that there is no permutation between any of those and `self`.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_succ()
[[4, 2, 3, 1]]
sage: p.permutohedron_succ(side='left')
[[4, 3, 1, 2]]
```

prev()

Return the permutation that comes directly before `self` in lexicographic order on the symmetric group containing `self`. If `self` is the first permutation, then it returns `False`.

EXAMPLES:

```
sage: p = Permutation([1,2,3])
sage: p.prev()
False
sage: p = Permutation([1,3,2])
sage: p.prev()
[1, 2, 3]
```

TESTS:

```
sage: p = Permutation([])
sage: p.prev()
False
```

Check that trac ticket #16913 is fixed:

```
sage: Permutation([1,4,3,2]).prev()
[1, 4, 2, 3]
```

rank()
Return the rank of `self` in the lexicographic ordering on the symmetric group to which `self` belongs.

EXAMPLES:

```
sage: Permutation([1,2,3]).rank()
0
sage: Permutation([1, 2, 4, 6, 3, 5]).rank()
10
sage: perms = Permutations(6).list()
sage: [p.rank() for p in perms ] == range(factorial(6))
True
```

recoils()
Return the list of the positions of the recoils of `self`.

A recoil of a permutation p is an integer i such that $i+1$ appears to the left of i in p. Here, the positions are being counted starting at 0. (Note that it is the positions, not the recoils themselves, which are being listed.)

EXAMPLES:

```
sage: Permutation([1,4,3,2]).recoils()
[2, 3]
sage: Permutation([]).recoils()
[]
```

recoils_composition()
Return the recoils composition of `self`.

The recoils composition of a permutation $p \in S_n$ is the composition of n whose descent set is the set of the recoils of p (not their positions). In other words, this is the descents composition of p^{-1}.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).recoils_composition()
[2, 2]
sage: Permutation([]).recoils_composition()
[]
```

reduced_word()
Return a reduced word of the permutation `self`.

See `reduced_words()` for the definition of reduced words and a way to compute them all.

Warning: This does not respect the multiplication convention.

EXAMPLES:

```
sage: Permutation([3,5,4,6,2,1]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]

Permutation([1]).reduced_word_lexmin()
[]
Permutation([]).reduced_word_lexmin()
[]
```

reduced_word_lexmin()
Return a lexicographically minimal reduced word of the permutation `self`.

See `reduced_words()` for the definition of reduced words and a way to compute them all.

EXAMPLES:

```
sage: Permutation([3,4,2,1]).reduced_word_lexmin()
[1, 2, 1, 3, 2]

Permutation([1]).reduced_word_lexmin()
[]
Permutation([]).reduced_word_lexmin()
[]
```

reduced_words()

Return a list of the reduced words of `self`.

The notion of a reduced word is based on the well-known fact that every permutation can be written as a product of adjacent transpositions. In more detail: If n is a nonnegative integer, we can define the transpositions $s_i = (i, i+1) \in S_n$ for all $i \in \{1, 2, \ldots, n-1\}$, and every $p \in S_n$ can then be written as a product $s_{i_1} s_{i_2} \cdots s_{i_k}$ for some sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n-1\}$ (here $\{1, 2, \ldots, n-1\}$ denotes the empty set when $n \leq 1$). Fixing a p, the sequences $(i_1, i_2, \ldots, i_k)$ of smallest length satisfying $p = s_{i_1} s_{i_2} \cdots s_{i_k}$ are called the reduced words of p. (Their length is the Coxeter length of p, and can be computed using `length()`.)

Note that the product of permutations is defined here in such a way that $(pq)(i) = p(q(i))$ for all permutations p and q and each $i \in \{1, 2, \ldots, n\}$ (this is the same convention as in `left_action_product()`, but not the default semantics of the $*$ operator on permutations in Sage). Thus, for instance, $s_2 s_1$ is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3.

See also:

`reduced_word()`, `reduced_word_lexmin()`

EXAMPLES:

```
sage: Permutation([2,1,3]).reduced_words()
[[1]]
sage: Permutation([3,1,2]).reduced_words()
[[2, 1]]
sage: Permutation([3,2,1]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
sage: Permutation([3,2,4,1]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]

Permutation([1]).reduced_words()
[[]]
Permutation([]).reduced_words()
[[]]
```

remove_extra_fixed_points()

Return the permutation obtained by removing any fixed points at the end of `self`.

EXAMPLES:

```
sage: Permutation([2,1,3]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([1,2,3,4]).remove_extra_fixed_points()
[1]
```

See also:

`retract_plain()`

retract_direct_product(m)

Return the direct-product retract of the permutation `self` $\in S_n$ to S_m, where $m \leq n$. If this retract is

undefined, then `None` is returned.

If $p \in S_n$ is a permutation, and m is a nonnegative integer less or equal to n, then the direct-product retract of p to S_m is defined only if $p([m]) = [m]$, where $[m]$ denotes the interval $\{1, 2, \ldots, m\}$. In this case, it is defined as the permutation written $(p(1), p(2), \ldots, p(m))$ in one-line notation.

EXAMPLES:

```
sage: Permutation([4,1,2,3,5]).retract_direct_product(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_direct_product(3)

sage: Permutation([1,4,2,3,6,5]).retract_direct_product(5)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(3)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(2)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(0)
[]

sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True
```

See also:

`retract_plain()`, `retract_okounkov_vershik()`

retract_okounkov_vershik(*m*)

Return the Okounkov-Vershik retract of the permutation `self` $\in S_n$ to S_m, where $m \leq n$.

If $p \in S_n$ is a permutation, and m is a nonnegative integer less or equal to n, then the Okounkov-Vershik retract of p to S_m is defined as the permutation in S_m which sends every $i \in \{1, 2, \ldots, m\}$ to $p^{k_i}(i)$, where k_i is the smallest positive integer k satisfying $p^k(i) \leq m$.

In other words, the Okounkov-Vershik retract of p is the permutation whose disjoint cycle decomposition is obtained by removing all letters strictly greater than m from the decomposition of p into disjoint cycles (and removing all cycles which are emptied in the process).

When $m = n - 1$, the Okounkov-Vershik retract (as a map $S_n \to S_{n-1}$) is the map $\widetilde{p}_n$ introduced in Section 7 of [OkounkovVershik2], and appears as (3.20) in [CST10]. In the general case, the Okounkov-Vershik retract of a permutation in S_n to S_m can be obtained by first taking its Okounkov-Vershik retract to S_{n-1}, then that of the resulting permutation to S_{n-2}, etc. until arriving in S_m.

REFERENCES:

EXAMPLES:

```
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(3)
[3, 1, 2]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(2)
[2, 1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(0)
[]

sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(5)
[1, 4, 2, 3, 5]
```

```
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(3)
[1, 3, 2]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(2)
[1, 2]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(0)
[]

sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(5)
[1, 5, 4, 3, 2]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(4)
[1, 2, 4, 3]

sage: Permutation([1,5,2,6,3,7,4,8]).retract_okounkov_vershik(4)
[1, 3, 2, 4]

sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True
```

See also:

retract_plain(), retract_direct_product()

retract_plain(*m*)

Return the plain retract of the permutation `self` in S_n to S_m, where $m \leq n$. If this retract is undefined, then `None` is returned.

If $p \in S_n$ is a permutation, and m is a nonnegative integer less or equal to n, then the plain retract of p to S_m is defined only if every $i > m$ satisfies $p(i) = i$. In this case, it is defined as the permutation written $(p(1), p(2), \ldots, p(m))$ in one-line notation.

EXAMPLES:

```
sage: Permutation([4,1,2,3,5]).retract_plain(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_plain(3)

sage: Permutation([1,3,2,4,5,6]).retract_plain(3)
[1, 3, 2]
sage: Permutation([1,3,2,4,5,6]).retract_plain(2)

sage: Permutation([1,2,3,4,5]).retract_plain(1)
[1]
sage: Permutation([1,2,3,4,5]).retract_plain(0)
[]

sage: all( p.retract_plain(3) == p for p in Permutations(3) )
True
```

See also:

retract_direct_product(), retract_okounkov_vershik(), remove_extra_fixed_points()

reverse()

Returns the permutation obtained by reversing the list.

EXAMPLES:

```
sage: Permutation([3,4,1,2]).reverse()
[2, 1, 4, 3]
sage: Permutation([1,2,3,4,5]).reverse()
[5, 4, 3, 2, 1]
```

right_action_product(*rp*)

Return the permutation obtained by composing `self` with `rp` in such an order that `self` is applied first and `rp` is applied afterwards.

This is usually denoted by either `self * rp` or `rp * self` depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by $p(i)$, then this should be denoted by `rp * self` in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all p, q and i). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by i^p, then this should be denoted by `self * rp` in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all p, q and i).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.right_action_product(q)
[1, 3, 2]
sage: q.right_action_product(p)
[3, 2, 1]
```

right_permutohedron_interval(*other*)

Return the list of the permutations belonging to the right permutohedron interval where `self` is the minimal element and `other` the maximal element.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval(Permutation([2, 5, 4, 1, 3]))
[[2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 4, 1, 5, 3], [2, 4, 5, 1, 3], [2, 5, 1, 4, 3], [2, 5,
```

TESTS:

```
sage: Permutation([]).right_permutohedron_interval(Permutation([]))
[[]]
sage: Permutation([3, 1, 2]).right_permutohedron_interval(Permutation([3, 1, 2]))
[[3, 1, 2]]
sage: Permutation([1, 3, 2, 4]).right_permutohedron_interval(Permutation([3, 4, 2, 1]))
[[1, 3, 2, 4], [1, 3, 4, 2], [3, 1, 2, 4], [3, 1, 4, 2], [3, 2, 1, 4], [3, 2, 4, 1], [3, 4,
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval(Permutation([2, 5, 4, 1, 3]))
[[2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 4, 1, 5, 3], [2, 4, 5, 1, 3], [2, 5, 1, 4, 3], [2, 5,
sage: Permutation([2, 5, 4, 1, 3]).right_permutohedron_interval(Permutation([2, 1, 4, 5, 3]))
Traceback (most recent call last):
...
ValueError: [2, 5, 4, 1, 3] must be lower or equal than [2, 1, 4, 5, 3] for the right permut
sage: Permutation([2, 4, 1, 3]).right_permutohedron_interval(Permutation([2, 1, 4, 5, 3]))
Traceback (most recent call last):
...
ValueError: len([2, 4, 1, 3]) and len([2, 1, 4, 5, 3]) must be equal
```

right_permutohedron_interval_iterator(*other*)

Return an iterator on the permutations (represented as integer lists) belonging to the right permutohedron interval where `self` is the minimal element and `other` the maximal element.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([2, 1, 4, 5, 3]).right_permutohedron_interval(Permutation([2, 5, 4, 1, 3])
[[2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 4, 1, 5, 3], [2, 4, 5, 1, 3], [2, 5, 1, 4, 3], [2, 5,
```

right_tableau()

Return the right standard tableau after performing the RSK algorithm on self.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).right_tableau()
[[1, 2], [3], [4]]
```

robinson_schensted()

Return the pair of standard tableaux obtained by running the Robinson-Schensted algorithm on self.

This can also be done by running RSK() on self (with the optional argument check_standard=True to return standard Young tableaux).

EXAMPLES:

```
sage: Permutation([6,2,3,1,7,5,4]).robinson_schensted()
[[[1, 3, 4], [2, 5], [6, 7]], [[1, 3, 5], [2, 6], [4, 7]]]
```

runs(*as_tuple=False*)

Return a list of the runs in the nonempty permutation self.

A run in a permutation is defined to be a maximal (with respect to inclusion) nonempty increasing substring (i. e., contiguous subsequence). For instance, the runs in the permutation [6,1,7,3,4,5,2] are [6], [1,7], [3,4,5] and [2].

Runs in an empty permutation are not defined.

INPUT:

- as_tuple – boolean (default: False) choice of output format

OUTPUT:

a list of lists or a tuple of tuples

REFERENCES:

- http://mathworld.wolfram.com/PermutationRun.html

EXAMPLES:

```
sage: Permutation([1,2,3,4]).runs()
[[1, 2, 3, 4]]
sage: Permutation([4,3,2,1]).runs()
[[4], [3], [2], [1]]
sage: Permutation([2,4,1,3]).runs()
[[2, 4], [1, 3]]
sage: Permutation([1]).runs()
[[1]]
```

The example from above:

```
sage: Permutation([6,1,7,3,4,5,2]).runs()
[[6], [1, 7], [3, 4, 5], [2]]
sage: Permutation([6,1,7,3,4,5,2]).runs(as_tuple=True)
((6,), (1, 7), (3, 4, 5), (2,))
```

The number of runs in a nonempty permutation equals its number of descents plus 1:

```
sage: all( len(p.runs()) == p.number_of_descents() + 1
....:      for p in Permutations(6) )
True
```

saliances()

Return a list of the saliances of the permutation `self`.

A saliance of a permutation p is an integer i such that $p(i) > p(j)$ for all $j > i$.

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).saliances()
[3, 4]
sage: Permutation([5,4,3,2,1]).saliances()
[0, 1, 2, 3, 4]
```

shifted_concatenation(*other*, *side='right'*)

Return the right (or left) shifted concatenation of `self` with a permutation `other`. These operations are also known as the Loday-Ronco over and under operations.

INPUT:

- `other` – a permutation, a list, a tuple, or any iterable representing a permutation.
- `side` – (default: `"right"`) the string "left" or "right".

OUTPUT:

If `side` is `"right"`, the method returns the permutation obtained by concatenating `self` with the letters of `other` incremented by the size of `self`. This is what is called `side / other` in [LodRon0102066], and denoted as the "over" operation. Otherwise, i. e., when `side` is `"left"`, the method returns the permutation obtained by concatenating the letters of `other` incremented by the size of `self` with `self`. This is what is called `side \ other` in [LodRon0102066] (which seems to use the $(\sigma\pi)(i) = \pi(\sigma(i))$ convention for the product of permutations).

EXAMPLES:

```
sage: Permutation([]).shifted_concatenation(Permutation([]), "right")
[]
sage: Permutation([]).shifted_concatenation(Permutation([]), "left")
[]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]), "right")
[2, 4, 1, 3, 7, 5, 6]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]), "left")
[7, 5, 6, 2, 4, 1, 3]
```

REFERENCES:

shifted_shuffle(*other*)

Return the shifted shuffle of two permutations `self` and `other`.

INPUT:

- `other` – a permutation, a list, a tuple, or any iterable representing a permutation.

OUTPUT:

The list of the permutations appearing in the shifted shuffle of the permutations `self` and `other`.

EXAMPLES:

```
sage: Permutation([]).shifted_shuffle(Permutation([]))
[[]]
sage: Permutation([1, 2, 3]).shifted_shuffle(Permutation([1]))
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [4, 1, 2, 3]]
sage: Permutation([1, 2]).shifted_shuffle(Permutation([2, 1]))
[[1, 2, 4, 3], [1, 4, 2, 3], [1, 4, 3, 2], [4, 1, 2, 3], [4, 1, 3, 2], [4, 3, 1, 2]]
sage: Permutation([1]).shifted_shuffle([1])
[[1, 2], [2, 1]]
sage: len(Permutation([3, 1, 5, 4, 2]).shifted_shuffle(Permutation([2, 1, 4, 3])))
126
```

The shifted shuffle product is associative. We can test this on an admittedly toy example:

```
sage: all( all( all( sorted(flatten([abs.shifted_shuffle(c)
....:                                for abs in a.shifted_shuffle(b)]))
....:                == sorted(flatten([a.shifted_shuffle(bcs)
....:                                   for bcs in b.shifted_shuffle(c)]))
....:                for c in Permutations(2) )
....:           for b in Permutations(2) )
....:      for a in Permutations(2) )
True
```

The `shifted_shuffle` method on permutations gives the same permutations as the `shifted_shuffle` method on words (but is faster):

```
sage: all( all( sorted(p1.shifted_shuffle(p2))
....:           == sorted([Permutation(p) for p in
....:                      Word(p1).shifted_shuffle(Word(p2))])
....:           for p2 in Permutations(3) )
....:      for p1 in Permutations(2) )
True
```

show(*representation='cycles'*, *orientation='landscape'*, ***args*)

Display the permutation as a drawing.

INPUT:

- `representation` – different kinds of drawings are available
  - `"cycles"` (default) – the permutation is displayed as a collection of directed cycles
  - `"braid"` – the permutation is displayed as segments linking each element $1, ..., n$ to its image on a parallel line.

    When using this drawing, it is also possible to display the permutation horizontally (`orientation = "landscape"`, default option) or vertically (`orientation = "portrait"`).
  - `"chord-diagram"` – the permutation is displayed as a directed graph, all of its vertices being located on a circle.

All additional arguments are forwarded to the `show` subcalls.

EXAMPLES:

```
sage: Permutations(20).random_element().show(representation = "cycles")
sage: Permutations(20).random_element().show(representation = "chord-diagram")
sage: Permutations(20).random_element().show(representation = "braid")
sage: Permutations(20).random_element().show(representation = "braid", orientation='portrait
```

TESTS:

```
sage: Permutations(20).random_element().show(representation = "modern_art")
Traceback (most recent call last):
...
ValueError: The value of 'representation' must be equal to 'cycles', 'chord-diagram' or 'bra
```

sign()

Return the signature of the permutation `self`. This is $(-1)^l$, where l is the number of inversions of `self`.

Note: `sign()` can be used as an alias for `signature()`.

EXAMPLES:

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
sage: Permutation([1,3,2,5,4]).sign()
1
sage: Permutation([]).sign()
1
```

signature()

Return the signature of the permutation `self`. This is $(-1)^l$, where l is the number of inversions of `self`.

Note: `sign()` can be used as an alias for `signature()`.

EXAMPLES:

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
sage: Permutation([1,3,2,5,4]).sign()
1
sage: Permutation([]).sign()
1
```

simion_schmidt(*avoid=[1, 2, 3]*)

Implements the Simion-Schmidt map which sends an arbitrary permutation to a pattern avoiding permutation, where the permutation pattern is one of four length-three patterns. This method also implements the bijection between (for example) `[1,2,3]`- and `[1,3,2]`-avoiding permutations.

INPUT:

- `avoid` – one of the patterns `[1,2,3]`, `[1,3,2]`, `[3,1,2]`, `[3,2,1]`.

EXAMPLES:

```
sage: P=Permutations(6)
sage: p=P([4,5,1,6,3,2])
sage: pl= [ [1,2,3], [1,3,2], [3,1,2], [3,2,1] ]
sage: for q in pl:
....:     s=p.simion_schmidt(q)
....:     print s, s.has_pattern(q)
....:
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: Permutation([3,4,1,2,5]).size()
5
```

sylvester_class(*left_to_right=False*)

Iterate over the equivalence class of the permutation `self` under sylvester congruence.

Sylvester congruence is an equivalence relation on the set S_n of all permutations of n. It is defined as the smallest equivalence relation such that every permutation of the form $uacvbw$ with u, v and w being words and a, b and c being letters satisfying $a \leq b < c$ is equivalent to the permutation $ucavbw$. (Here, permutations are regarded as words by way of one-line notation.) This definition comes from [HNT05], Definition 8, where it is more generally applied to arbitrary words.

The equivalence class of a permutation $p \in S_n$ under sylvester congruence is called the *sylvester class* of p. It is an interval in the right permutohedron order (see `permutohedron_lequal()`) on S_n.

This is related to the `sylvester_class()` method in that the equivalence class of a permutation π under sylvester congruence is the sylvester class of the right-to-left binary search tree of π. However, the present method yields permutations, while the method on labelled binary trees yields plain lists.

If the variable `left_to_right` is set to `True`, the method instead iterates over the equivalence class of `self` with respect to the *left* sylvester congruence. The left sylvester congruence is easiest to define by saying that two permutations are equivalent under it if and only if their reverses (`reverse()`) are equivalent under (standard) sylvester congruence.

EXAMPLES:

The sylvester class of a permutation in S_5:

```
sage: p = Permutation([3, 5, 1, 2, 4])
sage: sorted(p.sylvester_class())
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```

The sylvester class of a permutation p contains p:

```
sage: all( p in p.sylvester_class() for p in Permutations(4) )
True
```

Small cases:

```
sage: list(Permutation([]).sylvester_class())
[[]]

sage: list(Permutation([1]).sylvester_class())
[[1]]
```

The sylvester classes in S_3:

```
sage: [sorted(p.sylvester_class()) for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2], [3, 1, 2]],
 [[2, 1, 3]],
 [[2, 3, 1]],
```

```
 [[1, 3, 2], [3, 1, 2]],
 [[3, 2, 1]]]
```

The left sylvester classes in S_3:

```
sage: [sorted(p.sylvester_class(left_to_right=True)) for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2]],
 [[2, 1, 3], [2, 3, 1]],
 [[2, 1, 3], [2, 3, 1]],
 [[3, 1, 2]],
 [[3, 2, 1]]]
```

A left sylvester class in S_5:

```
sage: p = Permutation([4, 2, 1, 5, 3])
sage: sorted(p.sylvester_class(left_to_right=True))
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 5, 1],
 [4, 2, 5, 1, 3],
 [4, 2, 5, 3, 1],
 [4, 5, 2, 1, 3],
 [4, 5, 2, 3, 1]]
```

to_alternating_sign_matrix()

Return a matrix representing the permutation in the AlternatingSignMatrix class.

EXAMPLES:

```
sage: m = Permutation([1,2,3]).to_alternating_sign_matrix(); m
[1 0 0]
[0 1 0]
[0 0 1]
sage: parent(m)
Alternating sign matrices of size 3
```

to_cycles(*singletons=True*)

Return the permutation `self` as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If `singletons=False` is given, the list does not contain the singleton cycles.

EXAMPLES:

```
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]

sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
```

The algorithm is of complexity $O(n)$ where n is the size of the given permutation.

TESTS:

```
sage: from sage.combinat.permutation import from_cycles
sage: for n in range(1,6):
....:     for p in Permutations(n):
....:         if from_cycles(n, p.to_cycles()) != p:
....:             print "There is a problem with ",p
....:             break
sage: size = 10000
sage: sample = (Permutations(size).random_element() for i in range(5))
sage: all(from_cycles(size, p.to_cycles()) == p for p in sample)
True
```

Note: there is an alternative implementation called `_to_cycle_set` which could be slightly (10%) faster for some input (typically for permutations of size in the range [100, 10000]). You can run the following benchmarks. For small permutations:

```
sage: for size in range(9): # not tested
....:  print size
....:  lp = Permutations(size).list()
....:  timeit('[p.to_cycles(False) for p in lp]')
....:  timeit('[p._to_cycles_set(False) for p in lp]')
....:  timeit('[p._to_cycles_list(False) for p in lp]')
....:  timeit('[p._to_cycles_orig(False) for p in lp]')
```

and larger ones:

```
sage: for size in [10, 20, 50, 75, 100, 200, 500, 1000, # not tested
....:        2000, 5000, 10000, 15000, 20000, 30000,
....:        50000, 80000, 100000]:
....:     print(size)
....:     lp = [Permutations(size).random_element() for i in range(20)]
....:     timeit("[p.to_cycles() for p in lp]")
....:     timeit("[p._to_cycles_set() for p in lp]")
....:     timeit("[p._to_cycles_list() for p in lp]")
```

to_inversion_vector()

Return the inversion vector of `self`.

The inversion vector of a permutation $p \in S_n$ is defined as the vector $(v_1, v_2, \ldots, v_n)$, where v_i is the number of elements larger than i that appear to the left of i in the permutation p.

The algorithm is of complexity $O(n \log(n))$ where n is the size of the given permutation.

EXAMPLES:

```
sage: Permutation([5,9,1,8,2,6,4,7,3]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
sage: Permutation([8,7,2,1,9,4,6,5,10,3]).to_inversion_vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
sage: Permutation([3,2,4,1,5]).to_inversion_vector()
[3, 1, 0, 0, 0]
```

TESTS:

```
sage: from sage.combinat.permutation import from_inversion_vector
sage: all(from_inversion_vector(p.to_inversion_vector()) == p
....:   for n in range(6) for p in Permutations(n))
True

sage: P = Permutations(1000)
sage: sample = (P.random_element() for i in range(5))
```

```
sage: all(from_inversion_vector(p.to_inversion_vector()) == p
....:   for p in sample)
True
```

to_lehmer_cocode()

Return the Lehmer cocode of the permutation `self`.

The Lehmer cocode of a permutation p is defined as the list $(c_1, c_2, \ldots, c_n)$, where c_i is the number of $j < i$ such that $p(j) > p(i)$.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_cocode()
[0, 1, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_cocode()
[0, 1, 1]
```

to_lehmer_code()

Return the Lehmer code of the permutation `self`.

The Lehmer code of a permutation p is defined as the list $[c[1], c[2], ..., c[n]]$, where $c[i]$ is the number of $j > i$ such that $p(j) < p(i)$.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_code()
[1, 0, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_code()
[2, 0, 0]

sage: Permutation([1]).to_lehmer_code()
[0]
sage: Permutation([]).to_lehmer_code()
[]
```

TESTS:

```
sage: from sage.combinat.permutation import from_lehmer_code
sage: all(from_lehmer_code(p.to_lehmer_code()) == p
....:   for n in range(6) for p in Permutations(n))
True

sage: P = Permutations(1000)
sage: sample = (P.random_element() for i in range(5))
sage: all(from_lehmer_code(p.to_lehmer_code()) == p
....:   for p in sample)
True
```

to_major_code(*final_descent=False*)

Return the major code of the permutation `self`.

The major code of a permutation p is defined as the sequence $(m_1 - m_2, m_2 - m_3, \ldots, m_n)$, where m_i is the major index of the permutation obtained by erasing all letters smaller than i from p.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent. This has an effect on the computation of major indices.

REFERENCES:

•Carlitz, L. *q-Bernoulli and Eulerian Numbers*. Trans. Amer. Math. Soc. 76 (1954) 332-350. http://www.ams.org/journals/tran/1954-076-02/S0002-9947-1954-0060538-2/

•Skandera, M. *An Eulerian Partner for Inversions*. Sem. Lothar. Combin. 46 (2001) B46d. http://www.lehigh.edu/~mas906/papers/partner.ps

EXAMPLES:

```
sage: Permutation([9,3,5,7,2,1,4,6,8]).to_major_code()
[5, 0, 1, 0, 1, 2, 0, 1, 0]
sage: Permutation([2,8,4,3,6,7,9,5,1]).to_major_code()
[8, 3, 3, 1, 4, 0, 1, 0, 0]
```

to_matrix()

Return a matrix representing the permutation.

EXAMPLES:

```
sage: Permutation([1,2,3]).to_matrix()
[1 0 0]
[0 1 0]
[0 0 1]

sage: Permutation([1,3,2]).to_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

Notice that matrix multiplication corresponds to permutation multiplication only when the permutation option mult='r2l'

```
sage: PermutationOptions(mult='r2l')
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: (p*q).to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: p.to_matrix()*q.to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: PermutationOptions(mult='l2r')
sage: (p*q).to_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

to_permutation_group_element()

Returns a PermutationGroupElement equal to self.

EXAMPLES:

```
sage: Permutation([2,1,4,3]).to_permutation_group_element()
(1,2)(3,4)
sage: Permutation([1,2,3]).to_permutation_group_element()
()
```

to_tableau_by_shape(*shape*)

Return a tableau of shape `shape` with the entries in `self`. The tableau is such that the reading word (i.

e., the word obtained by reading the tableau row by row, starting from the top row in English notation, with each row being read from left to right) is `self`.

EXAMPLES:

```
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2])
[[1, 2, 5], [3, 4]]
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2]).reading_word_permutation()
[3, 4, 1, 2, 5]
```

weak_excedences()

Return all the numbers `self[i]` such that `self[i] >= i+1`.

EXAMPLES:

```
sage: Permutation([1,4,3,2,5]).weak_excedences()
[1, 4, 3, 5]
```

class sage.combinat.permutation.**Permutations**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Permutations.

`Permutations(n)` returns the class of permutations of `n`, if `n` is an integer, list, set, or string.

`Permutations(n, k)` returns the class of length-`k` partial permutations of `n` (where `n` is any of the above things); `k` must be a nonnegative integer. A length-k partial permutation of n is defined as a k-tuple of pairwise distinct elements of $\{1, 2, \ldots, n\}$.

Valid keyword arguments are: 'descents', 'bruhat_smaller', 'bruhat_greater', 'recoils_finer', 'recoils_fatter', 'recoils', and 'avoiding'. With the exception of 'avoiding', you cannot specify `n` or `k` along with a keyword.

`Permutations(descents=(list,n))` returns the class of permutations of n with descents in the positions specified by `list`. This uses the slightly nonstandard convention that the images of $1, 2, ..., n$ under the permutation are regarded as positions $0, 1, ..., n-1$, so for example the presence of 1 in `list` signifies that the permutations π should satisfy $\pi(2) > \pi(3)$. Note that `list` is supposed to be a list of positions of the descents, not the descents composition. It does *not* return the class of permutations with descents composition `list`.

`Permutations(bruhat_smaller=p)` and `Permutations(bruhat_greater=p)` return the class of permutations smaller-or-equal or greater-or-equal, respectively, than the given permutation `p` in the Bruhat order. (The Bruhat order is defined in `bruhat_lequal()`. It is also referred to as the *strong* Bruhat order.)

`Permutations(recoils=p)` returns the class of permutations whose recoils composition is `p`. Unlike the `descents=(list, n)` syntax, this actually takes a *composition* as input.

`Permutations(recoils_fatter=p)` and `Permutations(recoils_finer=p)` return the class of permutations whose recoils composition is fatter or finer, respectively, than the given composition `p`.

`Permutations(n, avoiding=P)` returns the class of permutations of `n` avoiding `P`. Here `P` may be a single permutation or a list of permutations; the returned class will avoid all patterns in `P`.

EXAMPLES:

```
sage: p = Permutations(3); p
Standard permutations of 3
sage: p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: p = Permutations(3, 2); p
Permutations of {1,...,3} of length 2
sage: p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
sage: p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']
sage: p.list()
[['c', 'a', 't'],
 ['c', 't', 'a'],
 ['a', 'c', 't'],
 ['a', 't', 'c'],
 ['t', 'c', 'a'],
 ['t', 'a', 'c']]

sage: p = Permutations(['c', 'a', 't'], 2); p
Permutations of the set ['c', 'a', 't'] of length 2
sage: p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]

sage: p = Permutations([1,1,2]); p
Permutations of the multi-set [1, 1, 2]
sage: p.list()
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]

sage: p = Permutations([1,1,2], 2); p
Permutations of the multi-set [1, 1, 2] of length 2
sage: p.list()
[[1, 1], [1, 2], [2, 1]]

sage: p = Permutations(descents=([1], 4)); p
Standard permutations of 4 with descents [1]
sage: p.list()
[[1, 3, 2, 4], [1, 4, 2, 3], [2, 3, 1, 4], [2, 4, 1, 3], [3, 4, 1, 2]]

sage: p = Permutations(bruhat_smaller=[1,3,2,4]); p
Standard permutations that are less than or equal to [1, 3, 2, 4] in the Bruhat order
sage: p.list()
[[1, 2, 3, 4], [1, 3, 2, 4]]

sage: p = Permutations(bruhat_greater=[4,2,3,1]); p
Standard permutations that are greater than or equal to [4, 2, 3, 1] in the Bruhat order
sage: p.list()
[[4, 2, 3, 1], [4, 3, 2, 1]]

sage: p = Permutations(recoils_finer=[2,1]); p
Standard permutations whose recoils composition is finer than [2, 1]
sage: p.list()
[[1, 2, 3], [1, 3, 2], [3, 1, 2]]

sage: p = Permutations(recoils_fatter=[2,1]); p
Standard permutations whose recoils composition is fatter than [2, 1]
sage: p.list()
[[1, 3, 2], [3, 1, 2], [3, 2, 1]]

sage: p = Permutations(recoils=[2,1]); p
Standard permutations whose recoils composition is [2, 1]
sage: p.list()
[[1, 3, 2], [3, 1, 2]]
```

```
sage: p = Permutations(4, avoiding=[1,3,2]); p
Standard permutations of 4 avoiding [1, 3, 2]
sage: p.list()
[[4, 1, 2, 3],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1],
 [3, 4, 1, 2],
 [3, 4, 2, 1],
 [2, 3, 4, 1],
 [3, 2, 4, 1],
 [1, 2, 3, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4]]

sage: p = Permutations(5, avoiding=[[3,4,1,2], [4,2,3,1]]); p
Standard permutations of 5 avoiding [[3, 4, 1, 2], [4, 2, 3, 1]]
sage: p.cardinality()
88
sage: p.random_element()
[5, 1, 2, 4, 3]
```

Element
alias of Permutation

global_options(**get_value*, ***set_value*)
Set the global options for elements of the permutation class. The defaults are for permutations to be displayed in list notation and the multiplication done from left to right (like in GAP) – that is, $(\pi\psi)(i) = \psi(\pi(i))$ for all i.

Note: These options have no effect on permutation group elements.

OPTIONS:

- `display` – (default: `list`) Specifies how the permutations should be printed
  - `cycle` – the permutations are displayed in cycle notation (i. e., as products of disjoint cycles)
  - `list` – the permutations are displayed in list notation (aka 1-line notation)
  - `reduced_expression` – alias for `reduced_word`
  - `reduced_word` – the permutations are displayed as reduced words
  - `singleton` – the permutations are displayed in cycle notation with singleton cycles shown as well
  - `word` – alias for `reduced_word`
- `generator_name` – (default: `s`) the letter used in latexing the reduced word
- `latex` – (default: `list`) Specifies how the permutations should be latexed
  - `cycle` – latex in cycle notation
  - `list` – latex as a list in one-line notation
  - `oneline` – alias for `list`

– `reduced_expression` – alias for `reduced_word`

– `reduced_word` – latex as reduced words

– `singleton` – latex in cycle notation with singleton cycles shown as well

– `twoline` – latex in two-line notation

– `word` – alias for `reduced_word`

- `latex_empty_str` – (default: `1`) The LaTeX representation of a reduced word when said word is empty
- `mult` – (default: `l2r`) The multiplication of permutations

  – `l2r` – left to right: $(p_1 \cdot p_2)(x) = p_2(p_1(x))$

  – `r2l` – right to left: $(p_1 \cdot p_2)(x) = p_1(p_2(x))$

EXAMPLES:

```
sage: p213 = Permutation([2,1,3])
sage: p312 = Permutation([3,1,2])
sage: Permutations.global_options(mult='l2r', display='list')
sage: Permutations.global_options['display']
'list'
sage: p213
[2, 1, 3]
sage: Permutations.global_options(display='cycle')
sage: p213
(1,2)
sage: Permutations.global_options(display='singleton')
sage: p213
(1,2)(3)
sage: Permutations.global_options(display='list')

sage: Permutations.global_options['mult']
'l2r'
sage: p213*p312
[1, 3, 2]
sage: Permutations.global_options(mult='r2l')
sage: p213*p312
[3, 2, 1]
sage: Permutations.global_options.reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.permutation.**PermutationsNK**(*s*, *k*)

Bases: sage.combinat.permutation.Permutations_setk

This exists solely for unpickling `PermutationsNK` objects created with Sage <= 6.3.

class sage.combinat.permutation.**Permutations_mset**(*mset*)

Bases: sage.combinat.permutation.Permutations

Permutations of a multiset M.

A permutation of a multiset M is represented by a list that contains exactly the same elements as M (with the same multiplicities), but possibly in different order. If M is a proper set there are $|M|!$ such permutations. Otherwise, if the first element appears k_1 times, the second element appears k_2 times and so on, the number of permutations is $|M|!/(k_1!k_2!\ldots)$, which is sometimes called a multinomial coefficient.

EXAMPLES:

```
sage: mset = [1,1,2,2,2]
sage: from sage.combinat.permutation import Permutations_mset
sage: P = Permutations_mset(mset); P
Permutations of the multi-set [1, 1, 2, 2, 2]
sage: sorted(P)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [1, 2, 2, 2, 1],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 1, 2, 2, 1],
 [2, 2, 1, 1, 2],
 [2, 2, 1, 2, 1],
 [2, 2, 2, 1, 1]]
sage: MS = MatrixSpace(GF(2),2,2)
sage: A = MS([1,0,1,1])
sage: rows = A.rows()
sage: rows[0].set_immutable()
sage: rows[1].set_immutable()
sage: P = Permutations_mset(rows); P
Permutations of the multi-set [(1, 0), (1, 1)]
sage: sorted(P)
[[(1, 0), (1, 1)], [(1, 1), (1, 0)]]
```

class Element

Bases: sage.structure.list_clone.ClonableArray

A permutation of an arbitrary multiset.

check()

Verify that self is a valid permutation of the underlying multiset.

EXAMPLES:

```
sage: S = Permutations(['c','a','c'])
sage: elt = S(['c','c','a'])
sage: elt.check()
```

Permutations_mset.**cardinality**()

EXAMPLES:

```
sage: Permutations([1,2,2]).cardinality()
3
sage: Permutations([1,1,2,2,2]).cardinality()
10
```

class sage.combinat.permutation.**Permutations_msetk**(*mset*, *k*)

Bases: sage.combinat.permutation.Permutations_mset

Length-k partial permutations of a multiset.

A length-k partial permutation of a multiset M is represented by a list of length k whose entries are elements of M, appearing in the list with a multiplicity not higher than their respective multiplicity in M.

class sage.combinat.permutation.**Permutations_nk**(n, k)

Bases: sage.combinat.permutation.Permutations

Length-k partial permutations of $\{1, 2, \ldots, n\}$.

class Element

Bases: sage.structure.list_clone.ClonableArray

A length-k partial permutation of $[n]$.

check()
Verify that `self` is a valid length-k partial permutation of $[n]$.

EXAMPLES:

```
sage: S = Permutations(4, 2)
sage: elt = S([3, 1])
sage: elt.check()
```

Permutations_nk.**cardinality**()
EXAMPLES:

```
sage: Permutations(3,0).cardinality()
1
sage: Permutations(3,1).cardinality()
3
sage: Permutations(3,2).cardinality()
6
sage: Permutations(3,3).cardinality()
6
sage: Permutations(3,4).cardinality()
0
```

Permutations_nk.**random_element**()
EXAMPLES:

```
sage: Permutations(3,2).random_element()
[0, 1]
```

class sage.combinat.permutation.**Permutations_set**(*s*)
Bases: sage.combinat.permutation.Permutations

Permutations of an arbitrary given finite set.

Here, a "permutation of a finite set S" means a list of the elements of S in which every element of S occurs exactly once. This is not to be confused with bijections from S to S, which are also often called permutations in literature.

class Element
Bases: sage.structure.list_clone.ClonableArray

A permutation of an arbitrary set.

check()
Verify that `self` is a valid permutation of the underlying set.

EXAMPLES:

```
sage: S = Permutations(['c','a','t'])
sage: elt = S(['t','c','a'])
sage: elt.check()
```

Permutations_set.**cardinality**()
EXAMPLES:

```
sage: Permutations([1,2,3]).cardinality()
6
```

Permutations_set.**random_element**()
EXAMPLES:

```
sage: Permutations([1,2,3]).random_element()
[1, 2, 3]
```

class sage.combinat.permutation.**Permutations_setk**(*s*, *k*)
Bases: sage.combinat.permutation.Permutations_set

Length-k partial permutations of an arbitrary given finite set.

Here, a "length-k partial permutation of a finite set S" means a list of length k whose entries are pairwise distinct and all belong to S.

random_element()
EXAMPLES:

```
sage: Permutations([1,2,3],2).random_element()
[1, 2]
```

class sage.combinat.permutation.**StandardPermutations_all**
Bases: sage.combinat.permutation.Permutations

All standard permutations.

class sage.combinat.permutation.**StandardPermutations_avoiding_12**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:

```
sage: P = Permutations(3, avoiding=[1, 2])
sage: TestSuite(P).run()
```

cardinality()
Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[1, 2])
sage: P.cardinality()
1
```

class sage.combinat.permutation.**StandardPermutations_avoiding_123**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:

```
sage: P = Permutations(3, avoiding=[2, 1, 3])
sage: TestSuite(P).run()
```

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[1, 2, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 2, 3]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_132**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:

```
sage: P = Permutations(3, avoiding=[1, 3, 2])
sage: TestSuite(P).run()
```

cardinality()
EXAMPLES:
```
sage: Permutations(5, avoiding=[1, 3, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 3, 2]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_21**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:
```
sage: P = Permutations(3, avoiding=[2, 1])
sage: TestSuite(P).run()
```

cardinality()
Return the cardinality of `self`.

EXAMPLES:
```
sage: P = Permutations(3, avoiding=[2, 1])
sage: P.cardinality()
1
```

class sage.combinat.permutation.**StandardPermutations_avoiding_213**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:
```
sage: P = Permutations(3, avoiding=[2, 1, 3])
sage: TestSuite(P).run()
```

cardinality()
EXAMPLES:
```
sage: Permutations(5, avoiding=[2, 1, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 1, 3]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_231**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:
```
sage: P = Permutations(3, avoiding=[2, 3, 1])
sage: TestSuite(P).run()
```

cardinality()
EXAMPLES:
```
sage: Permutations(5, avoiding=[2, 3, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 3, 1]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_312**(*n*)
Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:

```
sage: P = Permutations(3, avoiding=[3, 1, 2])
sage: TestSuite(P).run()
```

cardinality()

EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 1, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 1, 2]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_321**(n)

Bases: sage.combinat.permutation.StandardPermutations_avoiding_generic

TESTS:

```
sage: P = Permutations(3, avoiding=[3, 2, 1])
sage: TestSuite(P).run()
```

cardinality()

EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 2, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 2, 1]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_generic**(n, a)

Bases: sage.combinat.permutation.StandardPermutations_n_abstract

Generic class for subset of permutations avoiding a particular pattern.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[[2, 1, 3],[1,2,3]])
sage: P.cardinality()
4
```

class sage.combinat.permutation.**StandardPermutations_bruhat_greater**(p)

Bases: sage.combinat.permutation.Permutations

Permutations of $\{1, \ldots, n\}$ that are greater than or equal to a permutation p in the Bruhat order.

class sage.combinat.permutation.**StandardPermutations_bruhat_smaller**(p)

Bases: sage.combinat.permutation.Permutations

Permutations of $\{1, \ldots, n\}$ that are less than or equal to a permutation p in the Bruhat order.

class sage.combinat.permutation.**StandardPermutations_descents**(d, n)

Bases: sage.combinat.permutation.StandardPermutations_n_abstract

Permutations of $\{1, \ldots, n\}$ with a fixed set of descents.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(descents=([1,0,2],5))
sage: P.cardinality()
4
```

first()
Return the first permutation with descents d.

EXAMPLES:

```
sage: Permutations(descents=([1,0,4,8],12)).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

last()
Return the last permutation with descents d.

EXAMPLES:

```
sage: Permutations(descents=([1,0,4,8],12)).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

class sage.combinat.permutation.**StandardPermutations_n**(n)
Bases: sage.combinat.permutation.StandardPermutations_n_abstract

Permutations of the set $\{1, 2, \ldots, n\}$.

These are also called permutations of size n, or the elements of the n-th symmetric group.

Todo

Have a `reduced_word()` which works in both multiplication conventions.

---

class Element(*parent*, *l*, *check_input=True*)
Bases: sage.combinat.permutation.Permutation

Constructor. Checks that INPUT is not a mess, and calls `CombinatorialElement`. It should not, because `CombinatorialElement` is deprecated.

INPUT:

- `l` – a list of `int` variables
- `check_input` (boolean) – whether to check that input is correct. Slows the function down, but ensures that nothing bad happens.

  This is set to `True` by default.

TESTS:

```
sage: Permutation([1,2,3])
[1, 2, 3]
sage: Permutation([1,2,2,4])
Traceback (most recent call last):
...
ValueError: An element appears twice in the input. It should not.
sage: Permutation([1,2,4,-1])
Traceback (most recent call last):
...
ValueError: the elements must be strictly positive integers
sage: Permutation([1,2,4,5])
Traceback (most recent call last):
...
ValueError: The permutation has length 4 but its maximal element is
```

```
5. Some element may be repeated, or an element is missing, but there
is something wrong with its length.
```

has_left_descent(*i*, *mult=None*)

Check if `i` is a left descent of `self`.

A *left descent* of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n-1\}$ such that $s_i \circ \pi$ has smaller length than π. Here, $\circ$ denotes the multiplication of S_n. How it is defined depends on the `mult` variable in `Permutations.global_options()`. If this variable is set to `'l2r'`, then the multiplication is defined by the rule $(\alpha\beta)(x) = \beta(\alpha(x))$ for $\alpha, \beta \in S_n$ and $x \in \{1, 2, \ldots, n\}$; then, a left descent of π is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi(i) > \pi(i+1)$. If this variable is set to `'r2l'`, then the multiplication is defined by the rule $(\alpha\beta)(x) = \alpha(\beta(x))$ for $\alpha, \beta \in S_n$ and $x \in \{1, 2, \ldots, n\}$; then, a left descent of π is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi^{-1}(i) > \pi^{-1}(i+1)$.

The optional parameter `mult` can be set to `'l2r'` or `'r2l'`; if so done, it is used instead of the `mult` variable in `Permutations.global_options()`. Anyone using this method in a non-interactive environment is encouraged to do so in order to have code behave reliably.

Warning: The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

Warning: The optional input `mult` might disappear once trac ticket #14881 is fixed.

EXAMPLES:

```
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: x.descents() # known bug - different indices
[1, 3]
sage: [i for i in P.index_set() if x.has_left_descent(i)]
[1, 3]
sage: [i for i in P.index_set() if x.has_left_descent(i, mult="l2r")]
[1, 3]
sage: [i for i in P.index_set() if x.has_left_descent(i, mult="r2l")]
[1, 2]
```

has_right_descent(*i*, *mult=None*)

Check if `i` is a right descent of `self`.

A *right descent* of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n-1\}$ such that $\pi \circ s_i$ has smaller length than π. Here, $\circ$ denotes the multiplication of S_n. How it is defined depends on the `mult` variable in `Permutations.global_options()`. If this variable is set to `'l2r'`, then the multiplication is defined by the rule $(\alpha\beta)(x) = \beta(\alpha(x))$ for $\alpha, \beta \in S_n$ and $x \in \{1, 2, \ldots, n\}$; then, a right descent of π is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi^{-1}(i) > \pi^{-1}(i+1)$. If this variable is set to `'r2l'`, then the multiplication is defined by the rule $(\alpha\beta)(x) = \alpha(\beta(x))$ for $\alpha, \beta \in S_n$ and $x \in \{1, 2, \ldots, n\}$; then, a right descent of π is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi(i) > \pi(i+1)$.

The optional parameter `mult` can be set to `'l2r'` or `'r2l'`; if so done, it is used instead of the `mult` variable in `Permutations.global_options()`. Anyone using this method in a non-interactive environment is encouraged to do so in order to have code behave reliably.

Warning: The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

Warning: The optional input `mult` might disappear once trac ticket #14881 is fixed.

EXAMPLES:

```
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: (~x).descents() # known bug - different indices
[1, 2]
sage: [i for i in P.index_set() if x.has_right_descent(i)]
[1, 2]
sage: [i for i in P.index_set() if x.has_right_descent(i, mult="l2r")]
[1, 2]
sage: [i for i in P.index_set() if x.has_right_descent(i, mult="r2l")]
[1, 3]
```

inverse()

Return the inverse of `self`.

EXAMPLES:

```
sage: P = Permutations(4)
sage: w0 = P([4,3,2,1])
sage: w0.inverse() == w0
True
sage: w0.inverse().parent() is P
True
sage: P([3,2,4,1]).inverse()
[4, 2, 1, 3]
```

StandardPermutations_n.**algebra**(*base_ring*, *category=None*)

Return the symmetric group algebra associated to `self`.

INPUT:

- `base_ring` – a ring
- `category` – a category (default: the category of `self`)

EXAMPLES:

```
sage: P = Permutations(4)
sage: A = P.algebra(QQ); A
Symmetric group algebra of order 4 over Rational Field

sage: A.category()
Join of Category of coxeter group algebras over Rational Field
    and Category of finite group algebras over Rational Field
sage: A = P.algebra(QQ, category=Monoids())
sage: A.category()
Category of finite dimensional monoid algebras over Rational Field
```

StandardPermutations_n.**cardinality**()

Return the number of permutations of size n, which is $n!$.

EXAMPLES:

```
sage: Permutations(0).cardinality()
1
sage: Permutations(3).cardinality()
6
sage: Permutations(4).cardinality()
24
```

StandardPermutations_n.**cartan_type**()

Return the Cartan type of `self`.

The symmetric group S_n is a Coxeter group of type A_{n-1}.

EXAMPLES:

```
sage: A = SymmetricGroup([2,3,7]); A.cartan_type()
['A', 2]
sage: A = SymmetricGroup([]); A.cartan_type()
['A', 0]
```

StandardPermutations_n.**conjugacy_class**(*g*)

Return the conjugacy class of `g` in `self`.

INPUT:

- `g` – a partition or an element of `self`

EXAMPLES:

```
sage: G = Permutations(5)
sage: g = G([2,3,4,1,5])
sage: G.conjugacy_class(g)
Conjugacy class of cycle type [4, 1] in Standard permutations of 5
sage: G.conjugacy_class(Partition([2, 1, 1, 1]))
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5
```

StandardPermutations_n.**conjugacy_classes**()

Return a list of the conjugacy classes of `self`.

EXAMPLES:

```
sage: G = Permutations(4)
sage: G.conjugacy_classes()
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [4] in Standard permutations of 4]
```

StandardPermutations_n.**conjugacy_classes_iterator**()

Iterate over the conjugacy classes of `self`.

EXAMPLES:

```
sage: G = Permutations(4)
sage: list(G.conjugacy_classes_iterator()) == G.conjugacy_classes()
True
```

StandardPermutations_n.**conjugacy_classes_representatives**()

Return a complete list of representatives of conjugacy classes in `self`.

Let S_n be the symmetric group on n letters. The conjugacy classes are indexed by partitions λ of n. The ordering of the conjugacy classes is reverse lexicographic order of the partitions.

EXAMPLES:

```
sage: G = Permutations(5)
sage: G.conjugacy_classes_representatives()
[[1, 2, 3, 4, 5],
 [2, 1, 3, 4, 5],
 [2, 1, 4, 3, 5],
 [2, 3, 1, 4, 5],
 [2, 3, 1, 5, 4],
 [2, 3, 4, 1, 5],
 [2, 3, 4, 5, 1]]
```

TESTS:

Check some border cases:

```
sage: S = Permutations(0)
sage: S.conjugacy_classes_representatives()
[[]]
sage: S = Permutations(1)
sage: S.conjugacy_classes_representatives()
[[1]]
```

StandardPermutations_n.**element_in_conjugacy_classes**(*nu*)

Return a permutation with cycle type `nu`.

If the size of `nu` is smaller than the size of permutations in `self`, then some fixed points are added.

EXAMPLES:

```
sage: PP = Permutations(5)
sage: PP.element_in_conjugacy_classes([2,2])
[2, 1, 4, 3, 5]
```

StandardPermutations_n.**identity**()

Return the identity permutation of size n.

EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

StandardPermutations_n.**index_set**()

Return the index set for the descents of the symmetric group `self`.

This is $\{1, 2, \ldots, n-1\}$, where `self` is S_n.

EXAMPLES:

```
sage: P = Permutations(8)
sage: P.index_set()
(1, 2, 3, 4, 5, 6, 7)
```

StandardPermutations_n.**one**()

Return the identity permutation of size n.

EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
```

```
sage: Permutations(0).identity()
[]
```

StandardPermutations_n.**random_element**()

EXAMPLES:

```
sage: Permutations(4).random_element()
[1, 2, 4, 3]
```

StandardPermutations_n.**rank**(*p*)

EXAMPLES:

```
sage: SP3 = Permutations(3)
sage: map(SP3.rank, SP3)
[0, 1, 2, 3, 4, 5]
sage: SP0 = Permutations(0)
sage: map(SP0.rank, SP0)
[0]
```

StandardPermutations_n.**simple_reflection**(*i*)

For i in the index set of `self` (that is, for i in $\{1, 2, \ldots, n-1\}$, where `self` is S_n), this returns the elementary transposition $s_i = (i, i+1)$.

EXAMPLES:

```
sage: P = Permutations(4)
sage: P.simple_reflection(2)
[1, 3, 2, 4]
sage: P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}
```

StandardPermutations_n.**unrank**(*r*)

EXAMPLES:

```
sage: SP3 = Permutations(3)
sage: l = map(SP3.unrank, range(6))
sage: l == SP3.list()
True
sage: SP0 = Permutations(0)
sage: l = map(SP0.unrank, range(1))
sage: l == SP0.list()
True
```

class sage.combinat.permutation.**StandardPermutations_n_abstract**(*n*, *category=None*)

Bases: sage.combinat.permutation.Permutations

Abstract base class for subsets of permutations of the set $\{1, 2, \ldots, n\}$.

Warning: Anyone inheriting from this class should override the __contains__ method.

class sage.combinat.permutation.**StandardPermutations_recoils**(*recoils*)

Bases: sage.combinat.permutation.Permutations

Permutations of $\{1, \ldots, n\}$ with a fixed recoils composition.

class sage.combinat.permutation.**StandardPermutations_recoilsfatter**(*recoils*)

Bases: sage.combinat.permutation.Permutations

TESTS:

```
sage: P = Permutations(recoils_fatter=[2,2])
sage: TestSuite(P).run()
```

class sage.combinat.permutation.**StandardPermutations_recoilsfiner**(*recoils*)
Bases: sage.combinat.permutation.Permutations

TESTS:

```
sage: P = Permutations(recoils_finer=[2,2])
sage: TestSuite(P).run()
```

sage.combinat.permutation.**bistochastic_as_sum_of_permutations**(*M*, *check=True*)
Return the positive sum of permutations corresponding to the bistochastic matrix `M`.

A stochastic matrix is a matrix with nonnegative real entries such that the sum of the elements of any row is equal to 1. A bistochastic matrix is a stochastic matrix whose transpose matrix is also stochastic (there are conditions both on the rows and on the columns).

According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can be written as a convex combination of permutation matrices, which also means that the polytope of bistochastic matrices is integer.

As a non-bistochastic matrix can obviously not be written as a convex combination of permutations, this theorem is an equivalence.

This function, given a bistochastic matrix, returns the corresponding decomposition.

INPUT:

- `M` – A bistochastic matrix
- `check` (boolean) – set to `True` (default) to check that the matrix is indeed bistochastic

OUTPUT:

- An element of `CombinatorialFreeModule`, which is a free F-module (where F is the ground ring of the given matrix) whose basis is indexed by the permutations.

Note:

- In this function, we just assume 1 to be any constant : for us a matrix M is bistochastic if there exists $c > 0$ such that M/c is bistochastic.
- You can obtain a sequence of pairs `(permutation,coeff)`, where `permutation` is a Sage `Permutation` instance, and `coeff` its corresponding coefficient from the result of this function by applying the `list` function.
- If you are interested in the matrix corresponding to a `Permutation` you will be glad to learn about the `Permutation.to_matrix()` method.
- The base ring of the matrix can be anything that can be coerced to `RR`.

See also:

- `as_sum_of_permutations()` to use this method through the `Matrix` class.

EXAMPLES:

We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from the matrix:

```
sage: from sage.combinat.permutation import bistochastic_as_sum_of_permutations
sage: L = []
sage: L.append((9,Permutation([4, 1, 3, 5, 2])))
sage: L.append((6,Permutation([5, 3, 4, 1, 2])))
sage: L.append((3,Permutation([3, 1, 4, 2, 5])))
sage: L.append((2,Permutation([1, 4, 2, 3, 5])))
sage: M = sum([c * p.to_matrix() for (c,p) in L])
sage: decomp = bistochastic_as_sum_of_permutations(M)
sage: print decomp
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]] + 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, 1, 2]]
```

An exception is raised when the matrix is not positive and bistochastic:

```
sage: M = Matrix([[2,3],[2,2]])
sage: decomp = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
...
ValueError: The matrix is not bistochastic

sage: bistochastic_as_sum_of_permutations(Matrix(GF(7), 2, [2,1,1,2]))
Traceback (most recent call last):
...
ValueError: The base ring of the matrix must have a coercion map to RR

sage: bistochastic_as_sum_of_permutations(Matrix(ZZ, 2, [2,-1,-1,2]))
Traceback (most recent call last):
...
ValueError: The matrix should have nonnegative entries
```

sage.combinat.permutation.**bruhat_lequal**(*p1*, *p2*)

Return `True` if `p1` is less than `p2` in the Bruhat order.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.bruhat_lequal([2,4,3,1],[3,4,2,1])
True
```

sage.combinat.permutation.**descents_composition_first**(*dc*)

Compute the smallest element of a descent class having a descent composition `dc`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_first([1,1,3,4,3])
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

sage.combinat.permutation.**descents_composition_last**(*dc*)

Return the largest element of a descent class having a descent composition `dc`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_last([1,1,3,4,3])
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

sage.combinat.permutation.**descents_composition_list**(*dc*)

Return a list of all the permutations that have the descent composition `dc`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_list([1,2,2])
[[2, 1, 4, 3, 5],
 [2, 1, 5, 3, 4],
 [3, 1, 4, 2, 5],
 [3, 1, 5, 2, 4],
 [4, 1, 3, 2, 5],
 [5, 1, 3, 2, 4],
 [4, 1, 5, 2, 3],
 [5, 1, 4, 2, 3],
 [3, 2, 4, 1, 5],
 [3, 2, 5, 1, 4],
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4],
 [4, 2, 5, 1, 3],
 [5, 2, 4, 1, 3],
 [4, 3, 5, 1, 2],
 [5, 3, 4, 1, 2]]
```

sage.combinat.permutation.**from_cycles**(*n*, *cycles*, *parent=None*)

Return the permutation in the n-th symmetric group whose decomposition into disjoint cycles is `cycles`.

This function checks that its input is correct (i.e. that the cycles are disjoint and their elements integers among $1...n$). It raises an exception otherwise.

Warning: It assumes that the elements are of `int` type.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_cycles(4, [[1,2]])
[2, 1, 3, 4]
sage: permutation.from_cycles(4, [[1,2,4]])
[2, 4, 3, 1]
sage: permutation.from_cycles(10, [[3,1],[4,5],[6,8,9]])
[3, 2, 1, 5, 4, 8, 7, 9, 6, 10]
sage: permutation.from_cycles(10, ((2, 5), (6, 1, 3)))
[3, 5, 6, 4, 2, 1, 7, 8, 9, 10]
sage: permutation.from_cycles(4, [])
[1, 2, 3, 4]
sage: permutation.from_cycles(4, [[]])
[1, 2, 3, 4]
sage: permutation.from_cycles(0, [])
[]
```

Bad input (see trac ticket #13742):

```
sage: Permutation("(-12,2)(3,4)")
Traceback (most recent call last):
...
ValueError: All elements should be strictly positive integers, and I just found a non-positive c
sage: Permutation("(1,2)(2,4)")
Traceback (most recent call last):
...
ValueError: An element appears twice. It should not.
sage: permutation.from_cycles(4, [[1,18]])
Traceback (most recent call last):
```

```
...
ValueError: You claimed that this was a permutation on 1...4 but it contains 18
```

sage.combinat.permutation.**from_inversion_vector**(*iv*, *parent=None*)

Return the permutation corresponding to inversion vector `iv`.

See *sage.combinat.permutation.Permutation.to_inversion_vector* for a definition of the inversion vector of a permutation.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 8, 2, 6, 4, 7, 3]
sage: permutation.from_inversion_vector([0])
[1]
sage: permutation.from_inversion_vector([])
[]
```

sage.combinat.permutation.**from_lehmer_code**(*lehmer*, *parent=None*)

Return the permutation with Lehmer code `lehmer`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: lc = Permutation([2,1,5,4,3]).to_lehmer_code(); lc
[1, 0, 2, 1, 0]
sage: permutation.from_lehmer_code(lc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.**from_major_code**(*mc*, *final_descent=False*)

Return the permutation with major code `mc`.

The major code of a permutation is defined in `to_major_code()`.

Warning: This function creates illegal permutations (i.e. `Permutation([9])`, and this is dangerous as the `Permutation()` class is only designed to handle permutations on $1...n$. This will have to be changed when Sage permutations will be able to handle anything, but right now this should be fixed. Be careful with the results.

Warning: If `mc` is not a major index of a permutation, then the return value of this method can be anything. Garbage in, garbage out!

REFERENCES:

•Skandera, M. *An Eulerian Partner for Inversions*. Sem. Lothar. Combin. 46 (2001) B46d.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_major_code([5, 0, 1, 0, 1, 2, 0, 1, 0])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
sage: permutation.from_major_code([8, 3, 3, 1, 4, 0, 1, 0, 0])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
sage: Permutation([2,1,6,4,7,3,5]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
sage: permutation.from_major_code([3, 2, 0, 2, 2, 0, 0])
[2, 1, 6, 4, 7, 3, 5]
```

TESTS:

```
sage: permutation.from_major_code([])
[]

sage: all( permutation.from_major_code(p.to_major_code()) == p
....:      for p in Permutations(5) )
True
```

sage.combinat.permutation.**from_permutation_group_element**(*pge*, *parent=None*)

Return a Permutation given a PermutationGroupElement pge.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: pge = PermutationGroupElement([(1,2),(3,4)])
sage: permutation.from_permutation_group_element(pge)
[2, 1, 4, 3]
```

sage.combinat.permutation.**from_rank**(*n*, *rank*)

Return the permutation of the set $\{1, ..., n\}$ with lexicographic rank rank. This is the permutation whose Lehmer code is the factoradic representation of rank. In particular, the permutation with rank 0 is the identity permutation.

The permutation is computed without iterating through all of the permutations with lower rank. This makes it efficient for large permutations.

Note: The variable rank is not checked for being in the interval from 0 to $n! - 1$. When outside this interval, it acts as its residue modulo $n!$.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: Permutation([3, 6, 5, 4, 2, 1]).rank()
359
sage: [permutation.from_rank(3, i) for i in range(6)]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: Permutations(6)[10]
[1, 2, 4, 6, 3, 5]
sage: permutation.from_rank(6,10)
[1, 2, 4, 6, 3, 5]
```

sage.combinat.permutation.**from_reduced_word**(*rw*, *parent=None*)

Return the permutation corresponding to the reduced word rw.

See reduced_words() for a definition of reduced words and the convention on the order of multiplication used.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_reduced_word([3,2,3,1,2,3,1])
[3, 4, 2, 1]
sage: permutation.from_reduced_word([])
[]
```

sage.combinat.permutation.**permutohedron_lequal**(*p1*, *p2*, *side='right'*)

Return True if p1 is less than or equal to p2 in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,3]))
False
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,3]), side='left
True
```

sage.combinat.permutation.**to_standard**(*p*)

Return a standard permutation corresponding to the list `p`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.to_standard([4,2,7])
[2, 1, 3]
sage: permutation.to_standard([1,2,3])
[1, 2, 3]
sage: permutation.to_standard([])
[]
```

TESTS:

Does not mutate the list:

```
sage: a = [1,2,4]
sage: permutation.to_standard(a)
[1, 2, 3]
sage: a
[1, 2, 4]
```

5.1.148 Permutations (Cython file)

This is a nearly-straightforward implementation of what Knuth calls "Algorithm P" in TAOCP 7.2.1.2. The intent is to be able to enumerate permutation by "plain changes", or multiplication by adjacent transpositions, as a generator. This is useful when a class of objects is inherently enumerated by permutations, but it is faster to swap items in a permutation than construct the next object directly from the next permutation in a list. The backtracking algorithm in sage/graphs/genus.pyx is an example of this.

The lowest level is implemented as a struct with auxilliary methods. This is because Cython does not allow pointers to class instances, so a list of these objects is inherently slower than a list of structs. The author prefers ugly code to slow code.

For those willing to sacrifice a (very small) amount of speed, we provide a class that wraps our struct.

sage.combinat.permutation_cython.**left_action_product**(*S*, *lp*)

Return the permutation obtained by composing a permutation `S` with a permutation `lp` in such an order that `lp` is applied first and `S` is applied afterwards.

See also:

`sage.combinat.permutation.Permutation.left_action_product()`

EXAMPLES:

```
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_product
```

```
sage: left_action_product(p, q)
[3, 2, 1, 4]
sage: left_action_product(q, p)
[1, 3, 2, 4]
sage: q
[3, 1, 2]
```

sage.combinat.permutation_cython.**left_action_same_n**(*S*, *lp*)

Return the permutation obtained by composing a permutation `S` with a permutation `lp` in such an order that `lp` is applied first and `S` is applied afterwards and `S` and `lp` are of the same length.

See also:

`sage.combinat.permutation.Permutation.left_action_product()`

EXAMPLES:

```
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_same_n
sage: left_action_same_n(p, q)
[3, 2, 1]
sage: left_action_same_n(q, p)
[1, 3, 2]
```

sage.combinat.permutation_cython.**permutation_iterator_transposition_list**(*n*)

Returns a list of transposition indices to enumerate the permutations on n letters by adjacent transpositions. Assumes zero-based lists. We artificially limit the argument to $n < 12$ to avoid overflowing 32-bit pointers. While the algorithm works for larger n, the user is encouraged to avoid filling anything more than 4GB of memory with the output of this function.

EXAMPLES:

```
sage: import sage.combinat.permutation_cython
sage: from sage.combinat.permutation_cython import permutation_iterator_transposition_list
sage: permutation_iterator_transposition_list(4)
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]
sage: permutation_iterator_transposition_list(200)
Traceback (most recent call last):
...
ValueError: Cowardly refusing to enumerate the permutations on more than 12 letters.
sage: permutation_iterator_transposition_list(1)
[]

sage: # Generate the permutations of [1,2,3,4] fixing 4.
sage: Q = [1,2,3,4]
sage: L = [copy(Q)]
sage: for t in permutation_iterator_transposition_list(3):
...       Q[t], Q[t+1] = Q[t+1], Q[t]
...       L.append(copy(Q))
sage: print L
[[1, 2, 3, 4], [1, 3, 2, 4], [3, 1, 2, 4], [3, 2, 1, 4], [2, 3, 1, 4], [2, 1, 3, 4]]
```

sage.combinat.permutation_cython.**right_action_product**(*S*, *rp*)

Return the permutation obtained by composing a permutation `S` with a permutation `rp` in such an order that `S` is applied first and `rp` is applied afterwards.

See also:

`sage.combinat.permutation.Permutation.right_action_product()`

EXAMPLES:

```
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_product
sage: right_action_product(p, q)
[1, 3, 2, 4]
sage: right_action_product(q, p)
[3, 2, 1, 4]
sage: q
[3, 1, 2]
```

sage.combinat.permutation_cython.**right_action_same_n**(*S*, *rp*)

Return the permutation obtained by composing a permutation `S` with a permutation `rp` in such an order that `S` is applied first and `rp` is applied afterwards and `S` and `rp` are of the same length.

See also:

`sage.combinat.permutation.Permutation.right_action_product()`

EXAMPLES:

```
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_same_n
sage: right_action_same_n(p, q)
[1, 3, 2]
sage: right_action_same_n(q, p)
[3, 2, 1]
```

5.1.149 Posets

Common posets can be accessed through `posets.<tab>` and are listed in the posets catalog:

- *Catalog of posets*

Poset-related classes:

- *Finite posets*
- *Finite lattices and semilattices*
- *Linear Extensions of Posets*
- *Incidence Algebras*
- *Cartesian products of Posets*
- *Möbius Algebras*
- *Generalized Tamari lattices*
- *Tamari Interval-posets*
- *Shard intersection order*

If you are looking for Poset-related *categories*, see `Posets`, `FinitePosets`, `LatticePosets` and `FiniteLatticePosets`.

5.1.150 Poset features that are imported by default in the interpreter namespace

5.1.151 Cartesian products of Posets

AUTHORS:

- Daniel Krenn (2015)

class sage.combinat.posets.cartesian_product.**CartesianProductPoset**(*sets*, *category*, *order=None*, ***kwargs*)

Bases: sage.sets.cartesian_product.CartesianProduct

A class implementing Cartesian products of posets (and elements thereof). Compared to CartesianProduct you are able to specify an order for comparison of the elements.

INPUT:

- sets – a tuple of parents.
- category – a subcategory of Sets().CartesianProducts() & Posets().
- order – a string or function specifying an order less or equal. It can be one of the following:
  - 'native' – elements are ordered by their native ordering, i.e., the order the wrapped elements (tuples) provide.
  - 'lex' – elements are ordered lexicographically.
  - 'product' – an element is less or equal to another element, if less or equal is true for all its components (Cartesian projections).
  - A function which performs the comparison $\leq$. It takes two input arguments and outputs a boolean.

Other keyword arguments (kwargs) are passed to the constructor of CartesianProduct.

EXAMPLES:

```
sage: P = Poset((srange(3), lambda left, right: left <= right))
sage: Cl = cartesian_product((P, P), order='lex')
sage: Cl((1, 1)) <= Cl((2, 0))
True
sage: Cp = cartesian_product((P, P), order='product')
sage: Cp((1, 1)) <= Cp((2, 0))
False
sage: def le_sum(left, right):
....:     return (sum(left) < sum(right) or
....:             sum(left) == sum(right) and left[0] <= right[0])
sage: Cs = cartesian_product((P, P), order=le_sum)
sage: Cs((1, 1)) <= Cs((2, 0))
True
```

TESTS:

```
sage: Cl.category()
Join of Category of finite posets and
Category of Cartesian products of finite enumerated sets
sage: TestSuite(Cl).run()
sage: Cp.category()
Join of Category of finite posets and
Category of Cartesian products of finite enumerated sets
sage: TestSuite(Cp).run()
```

class Element

Bases: sage.sets.cartesian_product.CartesianProduct.Element

CartesianProductPoset.**le**(*left*, *right*)

Test whether left is less than or equal to right.

INPUT:

- left – an element.
- right – an element.

OUTPUT:

A boolean.

Note: This method uses the order defined on creation of this Cartesian product. See CartesianProductPoset.

EXAMPLES:

```
sage: P = Posets.ChainPoset(10)
sage: def le_sum(left, right):
....:     return (sum(left) < sum(right) or
....:             sum(left) == sum(right) and left[0] <= right[0])
sage: C = cartesian_product((P, P), order=le_sum)
sage: C.le(C((1, 6)), C((6, 1)))
True
sage: C.le(C((6, 1)), C((1, 6)))
False
sage: C.le(C((1, 6)), C((6, 6)))
True
sage: C.le(C((6, 6)), C((1, 6)))
False
```

CartesianProductPoset.**le_lex**(*left*, *right*)

Test whether left is lexicographically smaller or equal to right.

INPUT:

- left – an element.
- right – an element.

OUTPUT:

A boolean.

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='lex')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert(Q.le(a, b) == (a <= b))
....:         print '%s <= %s = %s' % (a, b, a <= b)
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
```

```
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

TESTS:

Check that trac ticket #19999 is resolved:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='product')
sage: R = cartesian_product((Q, P), order='lex')
sage: R(((1, 0), 0)) <= R(((0, 1), 0))
False
sage: R(((0, 1), 0)) <= R(((1, 0), 0))
False
```

CartesianProductPoset.**le_native**(*left*, *right*)

Test whether `left` is smaller or equal to `right` in the order provided by the elements themselves.

INPUT:

- `left` – an element.
- `right` – an element.

OUTPUT:

A boolean.

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='native')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert(Q.le(a, b) == (a <= b))
....:         print '%s <= %s = %s' % (a, b, a <= b)
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

CartesianProductPoset.**le_product**(*left*, *right*)

Test whether `left` is component-wise smaller or equal to `right`.

INPUT:

- `left` – an element.
- `right` – an element.

OUTPUT:

A boolean.

The comparison is `True` if the result of the comparision in each component is `True`.

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='product')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert(Q.le(a, b) == (a <= b))
....:         print '%s <= %s = %s' % (a, b, a <= b)
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = False
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

5.1.152 Elements of posets, lattices, semilattices, etc.

class sage.combinat.posets.elements.**JoinSemilatticeElement**(*poset*, *element*, *vertex*)

Bases: sage.combinat.posets.elements.PosetElement

Establishes the parent-child relationship between `poset` and `element`, where `element` is associated to the vertex `vertex` of the Hasse diagram of the poset.

INPUT:

- `poset` - a poset object
- `element` - any object
- `vertex` - a vertex of the Hasse diagram of the poset

TESTS:

```
sage: from sage.combinat.posets.elements import PosetElement
sage: P = Poset([[1,2],[4],[3],[4],[]], facade = False)
sage: e = P(0)
```

```
sage: e.parent() is P
True
sage: TestSuite(e).run()
```

class sage.combinat.posets.elements.**LatticePosetElement**(*poset*, *element*, *vertex*)
Bases: sage.combinat.posets.elements.MeetSemilatticeElement, sage.combinat.posets.elements.JoinSemilatticeElement

Establishes the parent-child relationship between `poset` and `element`, where `element` is associated to the vertex `vertex` of the Hasse diagram of the poset.

INPUT:

- `poset` - a poset object
- `element` - any object
- `vertex` - a vertex of the Hasse diagram of the poset

TESTS:

```
sage: from sage.combinat.posets.elements import PosetElement
sage: P = Poset([[1,2],[4],[3],[4],[]], facade = False)
sage: e = P(0)
sage: e.parent() is P
True
sage: TestSuite(e).run()
```

class sage.combinat.posets.elements.**MeetSemilatticeElement**(*poset*, *element*, *vertex*)
Bases: sage.combinat.posets.elements.PosetElement

Establishes the parent-child relationship between `poset` and `element`, where `element` is associated to the vertex `vertex` of the Hasse diagram of the poset.

INPUT:

- `poset` - a poset object
- `element` - any object
- `vertex` - a vertex of the Hasse diagram of the poset

TESTS:

```
sage: from sage.combinat.posets.elements import PosetElement
sage: P = Poset([[1,2],[4],[3],[4],[]], facade = False)
sage: e = P(0)
sage: e.parent() is P
True
sage: TestSuite(e).run()
```

class sage.combinat.posets.elements.**PosetElement**(*poset*, *element*, *vertex*)
Bases: sage.structure.element.Element

Establishes the parent-child relationship between `poset` and `element`, where `element` is associated to the vertex `vertex` of the Hasse diagram of the poset.

INPUT:

- `poset` - a poset object
- `element` - any object
- `vertex` - a vertex of the Hasse diagram of the poset

TESTS:

```
sage: from sage.combinat.posets.elements import PosetElement
sage: P = Poset([[1,2],[4],[3],[4],[]], facade = False)
sage: e = P(0)
sage: e.parent() is P
True
sage: TestSuite(e).run()
```

5.1.153 Hasse diagrams of posets

antichains()	Returns all antichains of self, organized as a prefix tree
antichains_iterator()	Return an iterator over the antichains of the poset.
are_comparable()	Returns whether i and j are comparable in the poset
are_incomparable()	Returns whether i and j are incomparable in the poset
bottom()	Returns the bottom element of the poset, if it exists.
cardinality()	Returns the number of elements in the poset.
chains()	Return all chains of self, organized as a prefix tree.
complements()	Deprecated.
cover_relations()	Return the list of cover relations.
cover_relations_iterator()	Iterate over cover relations.
covers()	Returns True if y covers x and False otherwise.
deprecated_function_alias()	Create an aliased version of a function or a method which raise a deprecation warning mes
dual()	Returns a poset that is dual to the given poset.
frattini_sublattice()	Return the list of elements of the Frattini sublattice of the lattice.
has_bottom()	Returns True if the poset has a unique minimal element.
has_top()	Returns True if the poset contains a unique maximal element, and False otherwise.
interval()	Return a list of the elements z of self such that $x \leq z \leq y$. The order is that induced by
is_bounded()	Returns True if the poset contains a unique maximal element and a unique minimal elemer
is_chain()	Returns True if the poset is totally ordered, and False otherwise.
is_complemented_lattice()	Return True if self is the Hasse diagram of a complemented lattice, and False otherw
is_distributive_lattice()	Returns True if self is the Hasse diagram of a distributive lattice, and False otherwise
is_gequal()	Returns True if x is greater than or equal to y, and False otherwise.
is_graded()	Deprecated, has conflicting definition of "graded" vs. "ranked" with posets.
is_greater_than()	Returns True if x is greater than but not equal to y, and False otherwise.
is_join_semilattice()	Returns True if self has a join operation, and False otherwise.
is_lequal()	Returns True if i is less than or equal to j in the poset, and False otherwise.
is_less_than()	Returns True if x is less than or equal to y in the poset, and False otherwise.
is_linear_extension()	Test if an ordering is a linear extension.
is_meet_semilattice()	Returns True if self has a meet operation, and False otherwise.
is_ranked()	Returns True if the poset is ranked, and False otherwise.
join_matrix()	Returns the matrix of joins of self. The (x,y)-entry of this matrix is the join of x and y
lequal_matrix()	Returns the matrix whose (i,j) entry is 1 if i is less than j in the poset, and 0 otherwise
linear_extension()	Return a linear extension
linear_extensions()	Return all linear extensions
lower_covers_iterator()	Returns the list of elements that are covered by element.
maximal_elements()	Returns a list of the maximal elements of the poset.
maximal_sublattices()	Return maximal sublattices of the lattice.
meet_matrix()	Returns the matrix of meets of self. The (x,y)-entry of this matrix is the meet of x and
minimal_elements()	Returns a list of the minimal elements of the poset.
moebius_function()	Returns the value of the Möbius function of the poset on the elements i and j.
moebius_function_matrix()	Returns the matrix of the Möbius function of this poset

Table 5.2 – continued from previous page

open_interval()	Return a list of the elements z of self such that $x < z < y$. The order is that induced by
order_filter()	Return the order filter generated by a list of elements.
order_ideal()	Return the order ideal generated by a list of elements.
principal_order_filter()	Returns the order filter generated by i.
principal_order_ideal()	Returns the order ideal generated by i.
pseudocomplement()	Return the pseudocomplement of element, if it exists.
rank()	Returns the rank of element, or the rank of the poset if element is None. (The rank of
rank_function()	Return the (normalized) rank function of the poset, if it exists.
top()	Returns the top element of the poset, if it exists.
upper_covers_iterator()	Returns the list of elements that cover element.

class sage.combinat.posets.hasse_diagram.**HasseDiagram**(*data=None*, *pos=None*, *loops=None*, *format=None*, *weighted=None*, *implementation='c_graph'*, *data_structure='sparse'*, *vertex_labels=True*, *name=None*, *multiedges=None*, *convert_empty_dict_labels_to_None=None*, *sparse=True*, *immutable=False*)

Bases: sage.graphs.digraph.DiGraph

The Hasse diagram of a poset. This is just a transitively-reduced, directed, acyclic graph without loops or multiple edges.

Note: We assume that range(n) is a linear extension of the poset. That is, range(n) is the vertex set and a topological sort of the digraph.

This should not be called directly, use Poset instead; all type checking happens there.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]}); H
Hasse diagram of a poset containing 4 elements
sage: TestSuite(H).run()
```

antichains(*element_class=<type 'list'>*)

Returns all antichains of self, organized as a prefix tree

INPUT:

- element_class – (default:list) an iterable type

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.antichains()
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
sage: [1,3] in A
True
sage: [1,4] in A
False
```

TESTS:

```
sage: TestSuite(A).run(skip = "_test_pickling")
```

Note: It's actually the pickling of the cached method `coxeter_transformation()` that fails ...

TESTS:

```
sage: A = Poset()._hasse_diagram.antichains()
sage: list(A)
[[]]
sage: TestSuite(A).run()
```

antichains_iterator()

Return an iterator over the antichains of the poset.

Note: The algorithm is based on Freese-Jezek-Nation p. 226. It does a depth first search through the set of all antichains organized in a prefix tree.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.antichains_iterator()
<generator object antichains_iterator at ...>
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[4],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]

sage: H = HasseDiagram({0:[],1:[],2:[]})
sage: list(H.antichains_iterator())
[[], [2], [1], [1, 2], [0], [0, 2], [0, 1], [0, 1, 2]]

sage: H = HasseDiagram({0:[1],1:[2],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [0]]
```

TESTS:

```
sage: H = Poset()._hasse_diagram
sage: list(H.antichains_iterator())
[[]]
```

are_comparable(i, j)

Returns whether `i` and `j` are comparable in the poset

INPUT:

- `i`, `j` – vertices of this Hasse diagram

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_comparable(1,2)
False
```

```
sage: [ (i,j) for i in H.vertices() for j in H.vertices() if H.are_comparable(i,j)]
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (1, 0), (1, 1), (1, 4), (2, 0), (2, 2), (2, 3), (2,
```

are_incomparable(*i*, *j*)

Returns whether `i` and `j` are incomparable in the poset

INPUT:

- `i`, `j` – vertices of this Hasse diagram

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_incomparable(1,2)
True
sage: [ (i,j) for i in H.vertices() for j in H.vertices() if H.are_incomparable(i,j)]
[(1, 2), (1, 3), (2, 1), (3, 1)]
```

bottom()

Returns the bottom element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

cardinality()

Returns the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).cardinality()
5
```

TESTS:

For a time, this function was named `size()`, which would override the same-named method of the underlying digraph. trac ticket #8735 renamed this method to `cardinality()` with a deprecation warning. trac ticket #11214 removed the warning since code for graphs was raising the warning inadvertently. This tests that `size()` for a Hasse diagram returns the number of edges in the digraph.

```
sage: L = Posets.BooleanLattice(5)
sage: H = L.hasse_diagram()
sage: H.size()
80
sage: H.size() == H.num_edges()
True
```

chains(*element_class=<type 'list'>*, *exclude=None*)

Return all chains of `self`, organized as a prefix tree.

INPUT:

- `element_class` – (default: `list`) an iterable type
- `exclude` – elements of the poset to be excluded (default: `None`)

OUTPUT:

The enumerated set (with a forest structure given by prefix ordering) consisting of all chains of `self`, each of which is given as an `element_class`.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.chains()
sage: list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4], [0, 3], [0, 3, 4],
sage: A.cardinality()
20
sage: [1,3] in A
False
sage: [1,4] in A
True
```

One can exclude some vertices:

```
sage: list(H.chains(exclude=[4, 3]))
[[], [0], [0, 1], [0, 2], [1], [2]]
```

The `element_class` keyword determines how the chains are being returned:

sage: P = Poset({1: [2, 3], 2: [4]}) sage: list(P._hasse_diagram.chains(element_class=tuple)) [(), (0,), (0, 1), (0, 1, 2), (0, 2), (0, 3), (1,), (1, 2), (2,), (3,)] sage: list(P._hasse_diagram.chains()) [[], [0], [0, 1], [0, 1, 2], [0, 2], [0, 3], [1], [1, 2], [2], [3]]

(Note that taking the Hasse diagram has renamed the vertices.)

sage: list(P._hasse_diagram.chains(element_class=tuple, exclude=[0])) [(), (1,), (1, 2), (2,), (3,)]

See also:

`antichains()`

closed_interval(*x*, *y*)

Return a list of the elements z of `self` such that $x \leq z \leq y$. The order is that induced by the ordering in `self.linear_extension`.

INPUT:

- `x` – any element of the poset
- `y` – any element of the poset

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

complements()

Deprecated.

cover_relations()

Return the list of cover relations.

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: H.cover_relations()
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]
```

cover_relations_iterator()

Iterate over cover relations.

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: list(H.cover_relations_iterator())
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]
```

covers(*x*, *y*)

Returns True if y covers x and False otherwise.

EXAMPLES:

```
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.covers(Q(1),Q(6))
True
sage: Q.covers(Q(1),Q(4))
False
```

coxeter_transformation()

Returns the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules.

EXAMPLES:

```
sage: M = Posets.PentagonPoset()._hasse_diagram.coxeter_transformation(); M
[ 0  0  0  0 -1]
[ 0  0  0  1 -1]
[ 0  1  0  0 -1]
[-1  1  1  0 -1]
[-1  1  0  1 -1]
```

TESTS:

```
sage: M = Posets.PentagonPoset()._hasse_diagram.coxeter_transformation()
sage: M**8 == 1
True
```

deprecated_function_alias(*trac_number*, *func*)

Create an aliased version of a function or a method which raise a deprecation warning message.

If f is a function or a method, write `g = deprecated_function_alias(trac_number, f)` to make a deprecated aliased version of f.

INPUT:

- `trac_number` – integer. The trac ticket number where the deprecation is introduced.
- `func` – the function or method to be aliased

EXAMPLES:

```
sage: from sage.misc.superseded import deprecated_function_alias
sage: g = deprecated_function_alias(13109, number_of_partitions)
sage: g(5)
```

```
doctest:...: DeprecationWarning: g is deprecated. Please use sage.combinat.partition.number_
See http://trac.sagemath.org/13109 for details.
7
```

This also works for methods:

```
sage: class cls(object):
....:     def new_meth(self): return 42
....:     old_meth = deprecated_function_alias(13109, new_meth)
sage: cls().old_meth()
doctest:...: DeprecationWarning: old_meth is deprecated. Please use new_meth instead.
See http://trac.sagemath.org/13109 for details.
42
```

trac ticket #11585:

```
sage: def a(): pass
sage: b = deprecated_function_alias(13109, a)
sage: b()
doctest:...: DeprecationWarning: b is deprecated. Please use a instead.
See http://trac.sagemath.org/13109 for details.
```

AUTHORS:

- Florent Hivert (2009-11-23), with the help of Mike Hansen.
- Luca De Feo (2011-07-11), printing the full module path when different from old path

dual()

Returns a poset that is dual to the given poset.

EXAMPLES:

```
sage: P = Posets.IntegerPartitions(4)
sage: H = P._hasse_diagram; H
Hasse diagram of a poset containing 5 elements
sage: H.dual()
Hasse diagram of a poset containing 5 elements
```

TESTS:

```
sage: H = Posets.IntegerPartitions(4)._hasse_diagram
sage: H.is_isomorphic( H.dual().dual() )
True
sage: H.is_isomorphic( H.dual() )
False
```

frattini_sublattice()

Return the list of elements of the Frattini sublattice of the lattice.

EXAMPLES:

```
sage: H = Posets.PentagonPoset()._hasse_diagram
sage: H.frattini_sublattice()
[0, 4]
```

has_bottom()

Returns True if the poset has a unique minimal element.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_bottom()
True
```

has_top()

Returns `True` if the poset contains a unique maximal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_top()
True
```

interval(x, y)

Return a list of the elements z of `self` such that $x \leq z \leq y$. The order is that induced by the ordering in `self.linear_extension`.

INPUT:

- x – any element of the poset
- y – any element of the poset

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

is_bounded()

Returns True if the poset contains a unique maximal element and a unique minimal element, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.is_bounded()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.is_bounded()
True
```

is_chain()

Returns True if the poset is totally ordered, and False otherwise.

EXAMPLES:

```
sage: L = Poset({0:[1],1:[2],2:[3],3:[4]})
sage: L.is_chain()
True
sage: V = Poset({0:[1,2]})
```

```
sage: V.is_chain()
False
```

TESTS:

Check trac ticket #15330:

```
sage: p = Poset(DiGraph({0:[1],2:[1]}))
sage: p.is_chain()
False
```

is_complemented_lattice()

Return `True` if `self` is the Hasse diagram of a complemented lattice, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2, 3], 1:[4], 2:[4], 3:[4]})
sage: H.is_complemented_lattice()
True

sage: H = HasseDiagram({0:[1, 2], 1:[3], 2:[3], 3:[4]})
sage: H.is_complemented_lattice()
False
```

is_distributive_lattice()

Returns `True` if `self` is the Hasse diagram of a distributive lattice, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_distributive_lattice()
False
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3]})
sage: H.is_distributive_lattice()
True
sage: H = HasseDiagram({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: H.is_distributive_lattice()
False
```

is_gequal(*x*, *y*)

Returns `True` if `x` is greater than or equal to `y`, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_gequal(x,y)
False
sage: Q.is_gequal(y,x)
False
sage: Q.is_gequal(x,z)
False
sage: Q.is_gequal(z,x)
True
sage: Q.is_gequal(z,y)
True
sage: Q.is_gequal(z,z)
True
```

is_graded()
Deprecated, has conflicting definition of "graded" vs. "ranked" with posets.

Return `True` if the Hasse diagram is ranked. For definition of ranked see `rank_function()`.

is_greater_than(*x*, *y*)
Returns `True` if `x` is greater than but not equal to `y`, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_greater_than(x,y)
False
sage: Q.is_greater_than(y,x)
False
sage: Q.is_greater_than(x,z)
False
sage: Q.is_greater_than(z,x)
True
sage: Q.is_greater_than(z,y)
True
sage: Q.is_greater_than(z,z)
False
```

is_join_semilattice()
Returns `True` if `self` has a join operation, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_join_semilattice()
True
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_join_semilattice()
False
sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H.is_join_semilattice()
False
```

is_lequal(*i*, *j*)
Returns True if i is less than or equal to j in the poset, and False otherwise.

Note: If the `lequal_matrix()` has been computed, then this method is redefined to use the cached matrix (see `_alternate_is_lequal()`).

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0, 1, 4
sage: H.is_lequal(x,y)
False
sage: H.is_lequal(y,x)
False
sage: H.is_lequal(x,z)
True
sage: H.is_lequal(y,z)
True
```

```
sage: H.is_lequal(z,z)
True
```

is_less_than(*x*, *y*)

Returns True if x is less than or equal to y in the poset, and False otherwise.

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0, 1, 4
sage: H.is_less_than(x,y)
False
sage: H.is_less_than(y,x)
False
sage: H.is_less_than(x,z)
True
sage: H.is_less_than(y,z)
True
sage: H.is_less_than(z,z)
False
```

is_linear_extension(*lin_ext=None*)

Test if an ordering is a linear extension.

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_linear_extension(range(4))
True
sage: H.is_linear_extension([3,2,1,0])
False
```

is_meet_semilattice()

Returns `True` if `self` has a meet operation, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_meet_semilattice()
True

sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_meet_semilattice()
True

sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_meet_semilattice()
False
```

is_ranked()

Returns True if the poset is ranked, and False otherwise.

A poset is *ranked* if it admits a rank function. For more information about the rank function, see `rank_function()` and `is_graded()`.

EXAMPLES:

```
sage: P = Poset([[1],[2],[3],[4],[]])
sage: P.is_ranked()
True
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.is_ranked()
False
```

join_matrix()

Returns the matrix of joins of `self`. The `(x,y)`-entry of this matrix is the join of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

Note: Once the matrix has been computed, it is stored in `_join_matrix()`. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.join_matrix()
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 7 6 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 7 5 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]
```

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.join_matrix()
Traceback (most recent call last):
...
ValueError: Not a join-semilattice: no top element.

sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H.join_matrix()
Traceback (most recent call last):
...
ValueError: No join for x=...
```

lequal_matrix()

Returns the matrix whose `(i,j)` entry is 1 if `i` is less than `j` in the poset, and 0 otherwise; and redefines `__lt__` to use this matrix.

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: H = P._hasse_diagram
sage: H.lequal_matrix()
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 1 0 1 1]
[0 0 0 1 0 0 0 1]
[0 0 0 0 1 0 0 1]
```

```
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
```

TESTS:

```
sage: H.lequal_matrix().is_immutable()
True
```

linear_extension()

Return a linear extension

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extension()
[0, 1, 2, 3]
```

linear_extensions()

Return all linear extensions

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extensions()
[[0, 1, 2, 3], [0, 2, 1, 3]]
```

lower_covers_iterator(*element*)

Returns the list of elements that are covered by `element`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: list(H.lower_covers_iterator(0))
[]
sage: list(H.lower_covers_iterator(4))
[1, 2]
```

maximal_elements()

Returns a list of the maximal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

maximal_sublattices()

Return maximal sublattices of the lattice.

EXAMPLES:

```
sage: L = Posets.PentagonPoset()
sage: ms = L._hasse_diagram.maximal_sublattices()
sage: sorted(ms, key=sorted)
[{0, 1, 2, 4}, {0, 1, 3, 4}, {0, 2, 3, 4}]
```

meet_matrix()

Returns the matrix of meets of `self`. The `(x,y)`-entry of this matrix is the meet of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

Note: Once the matrix has been computed, it is stored in `_meet_matrix()`. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.meet_matrix()
[0 0 0 0 0 0 0 0]
[0 1 0 0 1 0 0 1]
[0 0 2 0 2 2 2 2]
[0 0 0 3 0 0 3 3]
[0 1 2 0 4 2 2 4]
[0 0 2 0 2 5 2 5]
[0 0 2 3 2 2 6 6]
[0 1 2 3 4 5 6 7]
```

REFERENCE:

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.meet_matrix()
Traceback (most recent call last):
...
ValueError: Not a meet-semilattice: no bottom element.

sage: H = HasseDiagram({0:[1,2],1:[3,4],2:[3,4]})
sage: H.meet_matrix()
Traceback (most recent call last):
...
ValueError: No meet for x=...
```

minimal_elements()

Returns a list of the minimal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

mobius_function(**args*, ***kwds*)

Deprecated: Use `moebius_function()` instead. See trac ticket #19855 for details.

mobius_function_matrix(**args*, ***kwds*)

Deprecated: Use `moebius_function_matrix()` instead. See trac ticket #19855 for details.

moebius_function(*i*, *j*)

Returns the value of the Möbius function of the poset on the elements `i` and `j`.

EXAMPLES:

```
sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: H = P._hasse_diagram
sage: H.moebius_function(0,4)
2
sage: for u,v in P.cover_relations_iterator():
....:     if P.moebius_function(u,v) != -1:
....:         print "Bug in moebius_function!"
```

moebius_function_matrix()

Returns the matrix of the Möbius function of this poset

This returns the sparse matrix over $\mathbf{Z}$ whose `(x, y)` entry is the value of the Möbius function of `self` evaluated on `x` and `y`, and redefines `moebius_function()` to use it.

Note: The result is cached in `_moebius_function_matrix()`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.moebius_function_matrix()
[ 1 -1 -1 -1  1  0  1  0]
[ 0  1  0  0 -1  0  0  0]
[ 0  0  1  0 -1 -1 -1  2]
[ 0  0  0  1  0  0 -1  0]
[ 0  0  0  0  1  0  0 -1]
[ 0  0  0  0  0  1  0 -1]
[ 0  0  0  0  0  0  1 -1]
[ 0  0  0  0  0  0  0  1]
```

TESTS:

```
sage: H.moebius_function_matrix().is_immutable()
True
sage: hasattr(H,'_moebius_function_matrix')
True

sage: H.moebius_function == H._moebius_function_from_matrix
True
```

open_interval(x, y)

Return a list of the elements z of `self` such that $x < z < y$. The order is that induced by the ordering in `self.linear_extension`.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: set([5,6,4]) == set(H.open_interval(2,7))
True
sage: H.open_interval(7,2)
[]
```

order_filter(*elements*)

Return the order filter generated by a list of elements.

I is an order filter if, for any x in I and y such that $y \geq x$, then y is in I.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.order_filter([3,8])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

order_ideal(*elements*)

Return the order ideal generated by a list of elements.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal([7,10])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

principal_order_filter(*i*)

Returns the order filter generated by `i`.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_filter(2)
[2, 3, 6, 7, 10, 11, 14, 15]
```

principal_order_ideal(*i*)

Returns the order ideal generated by i.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_ideal(6)
[0, 2, 4, 6]
```

pseudocomplement(*element*)

Return the pseudocomplement of `element`, if it exists.

The pseudocomplement is the greatest element whose meet with given element is the bottom element. It may not exist, and then the function returns `None`.

INPUT:

- `element` – an element of the lattice.

OUTPUT:

An element of the Hasse diagram, i.e. an integer, or `None` if the pseudocomplement does not exist.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: H.pseudocomplement(2)
3

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.pseudocomplement(2) is None
True
```

rank(*element=None*)

Returns the rank of `element`, or the rank of the poset if `element` is `None`. (The rank of a poset is the length of the longest chain of elements of the poset.)

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.rank(5)
2
sage: H.rank()
3
sage: Q = HasseDiagram({0:[1,2],1:[3],2:[],3:[]})
sage: Q.rank()
2
sage: Q.rank(1)
1
```

rank_function()

Return the (normalized) rank function of the poset, if it exists.

A *rank function* of a poset P is a function r that maps elements of P to integers and satisfies: $r(x) = r(y) + 1$ if x covers y. The function r is normalized such that its minimum value on every connected component of the Hasse diagram of P is 0. This determines the function r uniquely (when it exists).

OUTPUT:

- a lambda function, if the poset admits a rank function
- None, if the poset does not admit a rank function

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4],[[1,4],[2,3],[3,4]]), facade = True)
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade = True)
sage: P.rank_function() is not None
False
sage: P = Poset(([1,2,3,4,5,6,7,8],[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade = True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

TESTS:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: r = P.rank_function()
sage: for u,v in P.cover_relations_iterator():
...     if r(v) != r(u) + 1:
...         print "Bug in rank_function!"

sage: Q = Poset([[1,2],[4],[3],[4],[]])
sage: Q.rank_function() is None
True
```

test for ticket trac ticket #14006:

```
sage: H = Poset()._hasse_diagram
sage: s = dumps(H)
```

```
sage: f = H.rank_function()
sage: s = dumps(H)
```

top()
Returns the top element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1
```

upper_covers_iterator(*element*)
Returns the list of elements that cover `element`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: list(H.upper_covers_iterator(0))
[1, 2, 3]
sage: list(H.upper_covers_iterator(7))
[]
```

5.1.154 Incidence Algebras

class sage.combinat.posets.incidence_algebras.**IncidenceAlgebra**(*R*, *P*, *prefix='I'*)
Bases: sage.combinat.free_module.CombinatorialFreeModule

The incidence algebra of a poset.

Let P be a poset and R be a commutative unital associative ring. The *incidence algebra* I_P is the algebra of functions $\alpha\colon P \times P \to R$ such that $\alpha(x, y) = 0$ if $x \not\leq y$ where multiplication is given by convolution:

$$(\alpha * \beta)(x, y) = \sum_{x \leq k \leq y} \alpha(x, k)\beta(k, y).$$

This has a natural basis given by indicator functions for the interval $[a, b]$, i.e. $X_{a,b}(x, y) = \delta_{ax}\delta_{by}$. The incidence algebra is a unital algebra with the identity given by the Kronecker delta $\delta(x, y) = \delta_{xy}$. The Möbius function of P is another element of I_p whose inverse is the ζ function of the poset (so $\zeta(x, y) = 1$ for every interval $[x, y]$).

Todo

Implement the incidence coalgebra.

REFERENCES:

- Wikipedia article Incidence_algebra

class Element(*M*, *x*)
Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element of an incidence algebra.

is_unit()
Return if `self` is a unit.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: mu = I.moebius()
sage: mu.is_unit()
True
sage: zeta = I.zeta()
sage: zeta.is_unit()
True
sage: x = mu - I.zeta() + I[2,2]
sage: x.is_unit()
False
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
True
```

This depends on the base ring:

```
sage: I = P.incidence_algebra(ZZ)
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
False
```

to_matrix()
Return `self` as a matrix.

We define a matrix $M_{xy} = \alpha(x, y)$ for some element $\alpha \in I_P$ in the incidence algebra I_P and we order the elements $x, y \in P$ by some linear extension of P. This defines an algebra (iso)morphism; in particular, multiplication in the incidence algebra goes to matrix multiplication.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius().to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
sage: I.zeta().to_matrix()
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

TESTS:

We check that this is an algebra (iso)morphism:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: mu = I.moebius()
sage: (mu*mu).to_matrix() == mu.to_matrix() * mu.to_matrix()
True
```

IncidenceAlgebra.**delta**()
Return the element 1 in `self` (which is the Kronecker delta $\delta(x, y)$).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
I[0, 0] + I[1, 1] + I[2, 2] + I[3, 3] + I[4, 4] + I[5, 5]
 + I[6, 6] + I[7, 7] + I[8, 8] + I[9, 9] + I[10, 10]
 + I[11, 11] + I[12, 12] + I[13, 13] + I[14, 14] + I[15, 15]
```

IncidenceAlgebra.**deprecated_function_alias**(*trac_number*, *func*)

Create an aliased version of a function or a method which raise a deprecation warning message.

If f is a function or a method, write `g = deprecated_function_alias(trac_number, f)` to make a deprecated aliased version of f.

INPUT:

- `trac_number` – integer. The trac ticket number where the deprecation is introduced.
- `func` – the function or method to be aliased

EXAMPLES:

```
sage: from sage.misc.superseded import deprecated_function_alias
sage: g = deprecated_function_alias(13109, number_of_partitions)
sage: g(5)
doctest:...: DeprecationWarning: g is deprecated. Please use sage.combinat.partition.number_
See http://trac.sagemath.org/13109 for details.
7
```

This also works for methods:

```
sage: class cls(object):
....:     def new_meth(self): return 42
....:     old_meth = deprecated_function_alias(13109, new_meth)
sage: cls().old_meth()
doctest:...: DeprecationWarning: old_meth is deprecated. Please use new_meth instead.
See http://trac.sagemath.org/13109 for details.
42
```

trac ticket #11585:

```
sage: def a(): pass
sage: b = deprecated_function_alias(13109, a)
sage: b()
doctest:...: DeprecationWarning: b is deprecated. Please use a instead.
See http://trac.sagemath.org/13109 for details.
```

AUTHORS:

- Florent Hivert (2009-11-23), with the help of Mike Hansen.
- Luca De Feo (2011-07-11), printing the full module path when different from old path

IncidenceAlgebra.**mobius**(**args*, ***kwds*)

Deprecated: Use `moebius()` instead. See trac ticket #19855 for details.

IncidenceAlgebra.**moebius**()

Return the Möbius function of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius()
```

```
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1]
 - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]
```

IncidenceAlgebra.**one**()

Return the element 1 in `self` (which is the Kronecker delta $\delta(x, y)$).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
I[0, 0] + I[1, 1] + I[2, 2] + I[3, 3] + I[4, 4] + I[5, 5]
 + I[6, 6] + I[7, 7] + I[8, 8] + I[9, 9] + I[10, 10]
 + I[11, 11] + I[12, 12] + I[13, 13] + I[14, 14] + I[15, 15]
```

IncidenceAlgebra.**poset**()

Return the defining poset of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.poset()
Finite lattice containing 16 elements
sage: I.poset() == P
True
```

IncidenceAlgebra.**product_on_basis**(*A*, *B*)

Return the product of basis elements indexed by `A` and `B`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.product_on_basis((1, 3), (3, 11))
I[1, 11]
sage: I.product_on_basis((1, 3), (2, 2))
0
```

IncidenceAlgebra.**reduced_subalgebra**(*prefix='R'*)

Return the reduced incidence subalgebra.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.reduced_subalgebra()
Reduced incidence algebra of Finite lattice containing 16 elements
 over Rational Field
```

IncidenceAlgebra.**some_elements**()

Return a list of elements of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(1)
sage: I = P.incidence_algebra(QQ)
sage: I.some_elements()
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
 I[0, 0] - I[0, 1] + I[1, 1],
 I[0, 0] + I[0, 1] + I[1, 1]]
```

IncidenceAlgebra.**zeta**()
Return the ζ function in self.

The ζ function on a poset P is given by

$$\zeta(x,y) = \begin{cases} 1 & x \leq y, \\ 0 & x \not\leq y. \end{cases}$$

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.zeta() * I.moebius() == I.one()
True
```

class sage.combinat.posets.incidence_algebras.**ReducedIncidenceAlgebra**(*I*, *prefix='R'*)
Bases: sage.combinat.free_module.CombinatorialFreeModule

The reduced incidence algebra of a poset.

The reduced incidence algebra R_P is a subalgebra of the incidence algebra I_P where $\alpha(x,y) = \alpha(x',y')$ when $[x,y]$ is isomorphic to $[x',y']$ as posets. Thus the delta, Möbius, and zeta functions are all elements of R_P.

class **Element**(*M*, *x*)
Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

An element of a reduced incidence algebra.

is_unit()
Return if self is a unit.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: x = R.an_element()
sage: x.is_unit()
True
```

lift()
Return the lift of self to the ambient space.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: R = I.reduced_subalgebra()
sage: x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: x.lift()
2*I[0, 0] + 2*I[0, 1] + 2*I[0, 2] + 3*I[0, 3] + 2*I[1, 1]
 + 2*I[1, 3] + 2*I[2, 2] + 2*I[2, 3] + 2*I[3, 3]
```

to_matrix()
Return self as a matrix.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: mu = R.moebius()
sage: mu.to_matrix()
[ 1 -1 -1  1]
```

```
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
```

ReducedIncidenceAlgebra.**delta**()

Return the Kronecker delta function in `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.delta()
R[(0, 0)]
```

ReducedIncidenceAlgebra.**deprecated_function_alias**(*trac_number*, *func*)

Create an aliased version of a function or a method which raise a deprecation warning message.

If f is a function or a method, write `g = deprecated_function_alias(trac_number, f)` to make a deprecated aliased version of f.

INPUT:

- `trac_number` – integer. The trac ticket number where the deprecation is introduced.
- `func` – the function or method to be aliased

EXAMPLES:

```
sage: from sage.misc.superseded import deprecated_function_alias
sage: g = deprecated_function_alias(13109, number_of_partitions)
sage: g(5)
doctest:...: DeprecationWarning: g is deprecated. Please use sage.combinat.partition.number_
See http://trac.sagemath.org/13109 for details.
7
```

This also works for methods:

```
sage: class cls(object):
....:     def new_meth(self): return 42
....:     old_meth = deprecated_function_alias(13109, new_meth)
sage: cls().old_meth()
doctest:...: DeprecationWarning: old_meth is deprecated. Please use new_meth instead.
See http://trac.sagemath.org/13109 for details.
42
```

trac ticket #11585:

```
sage: def a(): pass
sage: b = deprecated_function_alias(13109, a)
sage: b()
doctest:...: DeprecationWarning: b is deprecated. Please use a instead.
See http://trac.sagemath.org/13109 for details.
```

AUTHORS:

- Florent Hivert (2009-11-23), with the help of Mike Hansen.
- Luca De Feo (2011-07-11), printing the full module path when different from old path

ReducedIncidenceAlgebra.**lift**()

Return the lift morphism from `self` to the ambient space.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.lift
Generic morphism:
  From: Reduced incidence algebra of Finite lattice containing 4 elements over Rational Fiel
  To:   Incidence algebra of Finite lattice containing 4 elements over Rational Field
sage: R.an_element() - R.one()
R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: R.lift(R.an_element() - R.one())
I[0, 0] + 2*I[0, 1] + 2*I[0, 2] + 3*I[0, 3] + I[1, 1]
 + 2*I[1, 3] + I[2, 2] + 2*I[2, 3] + I[3, 3]
```

ReducedIncidenceAlgebra.**mobius**(**args*, ***kwds*)

Deprecated: Use `moebius()` instead. See trac ticket #19855 for details.

ReducedIncidenceAlgebra.**moebius**()

Return the Möbius function of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

ReducedIncidenceAlgebra.**one_basis**()

Return the index of the element 1 in `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.one_basis()
(0, 0)
```

ReducedIncidenceAlgebra.**poset**()

Return the defining poset of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.poset()
Finite lattice containing 16 elements
sage: R.poset() == P
True
```

ReducedIncidenceAlgebra.**some_elements**()

Return a list of elements of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.some_elements()
[2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)],
 R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)],
 R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]]
```

ReducedIncidenceAlgebra.**zeta**()

Return the ζ function in `self`.

The ζ function on a poset P is given by

$$\zeta(x,y) = \begin{cases} 1 & x \leq y, \\ 0 & x \not\leq y. \end{cases}$$

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.zeta()
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]
```

5.1.155 Finite lattices and semilattices

This module implements finite (semi)lattices. It defines:

`LatticePoset()`	Construct a lattice.
`MeetSemilattice()`	Construct a meet semi-lattice.
`JoinSemilattice()`	Construct a join semi-lattice.
`FiniteLatticePoset`	A class for finite lattices.
`FiniteMeetSemilattice`	A class for finite meet semilattices.
`FiniteJoinSemilattice`	A class for finite join semilattices.

List of (semi)lattice methods

Meet and join

`meet()`	Return the meet of given elements.
`join()`	Return the join of given elements.
`meet_matrix()`	Return the matrix of meets of all elements of the meet semi-lattice.
`join_matrix()`	Return the matrix of joins of all elements of the join semi-lattice.

Properties of the lattice

`is_distributive()`	Return `True` if the lattice is distributive.
`is_modular()`	Return `True` if the lattice is modular.
`is_lower_semimodular()`	Return `True` if the lattice is lower semimodular.
`is_upper_semimodular()`	Return `True` if the lattice is upper semimodular.
`is_atomic()`	Return `True` if every element of the lattice can be written as a join of atoms.
`is_geometric()`	Return `True` if the lattice is atomic and upper semimodular.
`is_complemented()`	Return `True` if every element of the lattice has at least one complement.
`is_pseudocomplemented()`	Return `True` if every element of the lattice has a pseudocomplement.
`is_supersolvable()`	Return `True` if the lattice is supersolvable.
`is_planar()`	Return `True` if the lattice has an upward planar drawing.
`is_dismantlable()`	Return `True` if the lattice is dismantlable.
`breadth()`	Return the breadth of the lattice.

Elements and sublattices

`complements()`	Return the list of complements of an element, or the dictionary of complements for all elements.
`pseudocomplement()`	Return the pseudocomplement of an element.
`is_modular_element()`	Return `True` if given element is modular in the lattice.
`sublattice()`	Return sublattice generated by list of elements.
`maximal_sublattices()`	Return maximal sublattices of the lattice.
`frattini_sublattice()`	Return the intersection of maximal sublattices of the lattice.

Miscellaneous

moebius_algebra()	Return the quantum Möbius algebra of the lattice.
quantum_moebius_algebra()	Return the quantum Möbius algebra of the lattice.

class sage.combinat.posets.lattices.**FiniteJoinSemilattice**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: sage.combinat.posets.posets.FinitePoset

We assume that the argument passed to FiniteJoinSemilattice is the poset of a join-semilattice (i.e. a poset with least upper bound for each pair of elements).

TESTS:

```
sage: J = JoinSemilattice([[1,2],[3],[3]])
sage: TestSuite(J).run()

sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P)
sage: TestSuite(J).run()
```

Element

alias of JoinSemilatticeElement

join(*x*, *y=None*)

Return the join of given elements in the lattice.

INPUT:

- x, y - two elements of the (semi)lattice OR
- x - a list or tuple of elements

EXAMPLES:

```
sage: D = Posets.DiamondPoset(5)
sage: D.join(1, 2)
4
sage: D.join(1, 1)
1
sage: D.join(1, 4)
4
sage: D.join(1, 0)
1
```

Using list of elements as an argument. Join of empty list is the bottom element:

```
sage: B4=Posets.BooleanLattice(4)
sage: B4.join([2,4,8])
14
sage: B4.join([])
0
```

Test that this method also works for facade lattices:

```
sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.join(1, 0)
1
sage: L.join(1, 2)
3
```

join_matrix()

Return a matrix whose (i,j) entry is k, where self.linear_extension()[k] is the join (least upper bound) of self.linear_extension()[i] and self.linear_extension()[j].

EXAMPLES:

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: J = P.join_matrix(); J
[0 1 2 3 4 5 6 7]
[1 1 3 3 7 7 7 7]
[2 3 2 3 4 6 6 7]
[3 3 3 3 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 7 5 6 7]
[6 7 6 7 7 6 6 7]
[7 7 7 7 7 7 7 7]
sage: J[P(4).vertex,P(3).vertex] == P(7).vertex
True
sage: J[P(5).vertex,P(2).vertex] == P(5).vertex
True
sage: J[P(5).vertex,P(2).vertex] == P(2).vertex
False
```

class sage.combinat.posets.lattices.**FiniteLatticePoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: sage.combinat.posets.lattices.FiniteMeetSemilattice, sage.combinat.posets.lattices.FiniteJoinSemilattice

We assume that the argument passed to FiniteLatticePoset is the poset of a lattice (i.e. a poset with greatest lower bound and least upper bound for each pair of elements).

TESTS:

```
sage: L = LatticePoset([[1,2],[3],[3]])
sage: TestSuite(L).run()

sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P)
sage: TestSuite(L).run()
```

Element

alias of LatticePosetElement

breadth(*certificate=False*)

Return the breadth of the lattice.

The breadth of a lattice is the largest integer n such that any join of elements $x_1, x_2, \ldots, x_{n+1}$ is join of a proper subset of x_i.

INPUT:

- certificate – (boolean; default: False) – whether to return an integer (the breadth) or a certificate, i.e. a biggest set whose join differs from the join of any subset.

EXAMPLES:

```
sage: D10 = Posets.DiamondPoset(10)
sage: D10.breadth()
2

sage: B3 = Posets.BooleanLattice(3)
sage: B3.breadth()
3
sage: B3.breadth(certificate=True)
[1, 2, 4]
```

Smallest example of a lattice with breadth 4:

```
sage: L = LatticePoset(DiGraph('O]???w?K_@S?E_??Q?@_?D??I??W?B??@??C??O?@???'))
sage: L.breadth()
4
```

ALGORITHM:

For a lattice to have breadth at least n, it must have an n-element antichain A with join j. Element j must cover at least n elements. There must also be $n-2$ levels of elements between A and j. So we start by searching elements that could be our j and then just check possible antichains A.

TESTS:

```
sage: Posets.ChainPoset(0).breadth()
0
sage: Posets.ChainPoset(1).breadth()
1
```

complements(*element=None*)

Return the list of complements of an element in the lattice, or the dictionary of complements for all elements.

Elements x and y are complements if their meet and join are respectively the bottom and the top element of the lattice.

INPUT:

- `element` - an element of the lattice whose complement is returned. If `None` (default) then dictionary of complements for all elements having at least one complement is returned.

EXAMPLES:

```
sage: L=LatticePoset({0:['a','b','c'], 'a':[1], 'b':[1], 'c':[1]})
sage: C = L.complements()
```

Let us check that $'a'$ and $'b'$ are complements of each other:

```
sage: 'a' in C['b']
True
sage: 'b' in C['a']
True
```

Full list of complements:

```
sage: L.complements() # random
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}

sage: L=LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.complements() # random
{0: [4], 4: [0]}
sage: L.complements(1)
[]
```

TESTS:

```
sage: L=LatticePoset({0:['a','b','c'], 'a':[1], 'b':[1], 'c':[1]})
sage: for v,v_complements in L.complements().items():
....:     for v_c in v_complements:
....:         assert L.meet(v,v_c) == L.bottom()
....:         assert L.join(v,v_c) == L.top()
```

frattini_sublattice()
Return the Frattini sublattice of the lattice.

The Frattini sublattice $\Phi(L)$ is the intersection of all proper maximal sublattices of L. It is also the set of "non-generators" - if the sublattice generated by set S of elements is whole lattice, then also $S \setminus \Phi(L)$ generates whole lattice.

EXAMPLES:

```
sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],
....:                         [2,5],[2,7],[17,22],[17,13],[8,7],
....:                         [8,13],[3,16],[3,9],[22,16],[22,18],
....:                         [22,10],[5,18],[5,14],[7,9],[7,14],
....:                         [7,10],[13,10],[16,6],[16,19],[9,19],
....:                         [18,6],[18,33],[14,33],[10,19],
....:                         [10,33],[6,4],[19,4],[33,4]] ))
sage: sorted(L.frattini_sublattice().list())
[1, 2, 4, 10, 19, 22, 33]
```

is_atomic()
Returns `True` if `self` is an atomic lattice and `False` otherwise.

A lattice is atomic if every element can be written as a join of atoms.

EXAMPLES:

```
sage: L = LatticePoset({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: L.is_atomic()
True

sage: L = LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.is_atomic()
False
```

NOTES:

See [Sta97], Section 3.3 for a discussion of atomic lattices.

REFERENCES:

is_complemented()
Returns `True` if `self` is a complemented lattice, and `False` otherwise.

EXAMPLES:

```
sage: L = LatticePoset({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: L.is_complemented()
True

sage: L = LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.is_complemented()
False
```

is_dismantlable(*certificate=False*)
Return `True` if the lattice is dismantlable, and `False` otherwise.

An n-element lattice L_n is dismantlable if there is a sublattice chain $L_{n-1} \supset L_{n-2}, \supset \cdots, \supset L_0$ so that every L_i is a sublattice of L_{i+1} with one element less, and L_0 is the empty lattice. In other words, a dismantlable lattice can be reduced to empty lattice removing doubly irreducible element one by one.

INPUT:

- `certificate` (boolean) – Whether to return a certificate.

– If `certificate = False` (default), returns `True` or `False` accordingly.

– If `certificate = True`, returns:

* `(True, elms)` when the lattice is dismantlable, where `elms` is elements listed in a possible removing order.

* `(False, crown)` when the lattice is not dismantlable, where `crown` is a subposet of $2k$ elements $a_1, \ldots, a_k, b_1, \ldots, b_k$ with covering relations $a_i \lessdot b_i$ and $a_i \lessdot b_{i+1}$ for $i \in [1, \ldots, k-1]$, and $a_k \lessdot b_1$.

EXAMPLES:

```
sage: DL12 = LatticePoset((divisors(12), attrcall("divides")))
sage: DL12.is_dismantlable()
True
sage: DL12.is_dismantlable(certificate=True)
(True, [4, 2, 1, 3, 6, 12])

sage: B3 = Posets.BooleanLattice(3)
sage: B3.is_dismantlable()
False
sage: B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
```

Every planar lattice is dismantlable. Converse is not true:

```
sage: L = LatticePoset( ([], [[0, 1], [0, 2], [0, 3], [0, 4],
....:                        [1, 7], [2, 6], [3, 5], [4, 5],
....:                        [4, 6], [4, 7], [5, 8], [6, 8],
....:                        [7, 8]]) )
sage: L.is_dismantlable()
True
sage: L.is_planar()
False
```

TESTS:

```
sage: Posets.ChainPoset(0).is_dismantlable()
True
sage: Posets.ChainPoset(1).is_dismantlable()
True

sage: L = LatticePoset(DiGraph('L@_?W?E?@CCO?A?@??_?O?Jw????C?'))
sage: L.is_dismantlable()
False
sage: c = L.is_dismantlable(certificate=True)[1]
sage: (3 in c, 12 in c, 9 in c)
(True, False, True)
```

is_distributive()

Return `True` if the lattice is distributive, and `False` otherwise.

A lattice $(L, \vee, \wedge)$ is distributive if meet distributes over join: $x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$ for every $x, y, z \in L$ just like $x \cdot (y + z) = x \cdot y + x \cdot z$ in normal arithmetic. For duality in lattices it follows that then also join distributes over meet.

EXAMPLES:

```
sage: L = LatticePoset({0:[1,2],1:[3],2:[3]})
sage: L.is_distributive()
True
```

```
sage: L = LatticePoset({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: L.is_distributive()
False
```

is_geometric()

Return `True` if the lattice is geometric, and `False` otherwise.

A lattice is geometric if it is both atomic and upper semimodular.

EXAMPLES:

Canonical example is the lattice of partitions of finite set ordered by refinement:

```
sage: S = SetPartitions(3)
sage: L = LatticePoset( (S, lambda a, b: S.is_less_than(a, b)) )
sage: L.is_geometric()
True
```

Smallest example of geometric lattice that is not modular:

```
sage: L = LatticePoset(DiGraph('K]?@g@S?q?M?@?@?@?@?@?@??'))
sage: L.is_geometric()
True
sage: L.is_modular()
False
```

Two non-examples:

```
sage: L = LatticePoset({1:[2, 3, 4], 2:[5, 6], 3:[5], 4:[6], 5:[7], 6:[7]})
sage: L.is_geometric()  # Graded, but not upper semimodular
False
sage: L = Posets.ChainPoset(3)
sage: L.is_geometric()  # Modular, but not atomic
False
```

TESTS:

```
sage: LatticePoset({}).is_geometric()
True
sage: LatticePoset({1:[]}).is_geometric()
True
```

is_lower_semimodular()

Return `True` if the lattice is lower semimodular and `False` otherwise.

A lattice is lower semimodular if for any x in the lattice that covers y and z, both y and z cover their meet.

See also `is_modular()` and `is_upper_semimodular()`.

See Wikipedia article Semimodular_lattice

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_lower_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_lower_semimodular()
False

sage: L = posets.ChainPoset(6)
```

```
sage: L.is_lower_semimodular()
True
```

ALGORITHM:

Based on pp. 286-287 of Enumerative Combinatorics, Vol 1 [EnumComb1].

is_modular(*L=None*)

Return `True` if the lattice is modular and `False` otherwise.

Using the parameter `L`, this can also be used to check that some subset of elements are all modular.

INPUT:

- `L` – (default: `None`) a list of elements to check being modular, if `L` is `None`, then this checks the entire lattice

An element x in a lattice L is *modular* if $x \leq b$ implies

$$x \vee (a \wedge b) = (x \vee a) \wedge b$$

for every $a, b \in L$. We say L is modular if x is modular for all $x \in L$. There are other equivalent definitions, see Wikipedia article Modular_lattice.

See also:

`is_upper_semimodular()`, `is_lower_semimodular()` and `is_modular_element()`

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_modular()
True

sage: L = posets.PentagonPoset()
sage: L.is_modular()
False

sage: L = posets.ChainPoset(6)
sage: L.is_modular()
True

sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular()
False
sage: [L.is_modular([x]) for x in L]
[True, True, False, True, True, False, True]
```

ALGORITHM:

Based on pp. 286-287 of Enumerative Combinatorics, Vol 1 [EnumComb1].

is_modular_element(*x*)

Return `True` if `x` is a modular element and `False` otherwise.

INPUT:

- `x` – an element of the lattice

An element x in a lattice L is *modular* if $x \leq b$ implies

$$x \vee (a \wedge b) = (x \vee a) \wedge b$$

for every $a, b \in L$.

See also:

`is_modular()` to check modularity for the full lattice or some set of elements

EXAMPLES:

```
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular()
False
sage: [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]
```

is_planar()

Return `True` if the lattice is *upward* planar, and `False` otherwise.

A lattice is upward planar if its Hasse diagram has a planar drawing in the $\mathbb{R}^2$ plane, in such a way that x is strictly below y (on the vertical axis) whenever $x < y$ in the lattice.

Note that the scientific litterature on posets often omits "upward" and shortens it to "planar lattice" (e.g. [GW14]), which can cause confusion with the notion of graph planarity in graph theory.

Note: Not all lattices which are planar – in the sense of graph planarity – admit such a planar drawing (see example below).

ALGORITHM:

Using the result from [Platt76], this method returns its result by testing that the Hasse diagram of the lattice is planar (in the sense of graph theory) when an edge is added between the top and bottom elements.

EXAMPLES:

The Boolean lattice of 2^3 elements is not upward planar, even if it's covering relations graph is planar:

```
sage: B3 = Posets.BooleanLattice(3)
sage: B3.is_planar()
False
sage: G = B3.cover_relations_graph()
sage: G.is_planar()
True
```

Ordinal product of planar lattices is obviously planar. Same does not apply to Cartesian products:

```
sage: P = Posets.PentagonPoset()
sage: Pc = P.product(P)
sage: Po = P.ordinal_product(P)
sage: Pc.is_planar()
False
sage: Po.is_planar()
True
```

TESTS:

```
sage: Posets.ChainPoset(0).is_planar()
True
sage: Posets.ChainPoset(1).is_planar()
True
```

REFERENCES:

is_pseudocomplemented()

Return `True` if the lattice is pseudocomplemented, and `False` otherwise.

A lattice is pseudocomplemented if every element e has a pseudocomplement $e^\star$, i.e. the greatest element such that the meet of e and $e^\star$ is the bottom element.

See Wikipedia article Pseudocomplement.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
....:                   5: [6], 6: [7]})
sage: L.is_pseudocomplemented()
True

sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
....:                   5: [7], 6: [7]})
sage: L.is_pseudocomplemented()  # Element 3 has no pseudocomplement
False
```

See also:

`sage.combinat.posets.lattices.FiniteMeetSemilattice.pseudocomplement()`.

TESTS:

```
sage: LatticePoset({}).is_pseudocomplemented()
True
```

is_supersolvable()

Return `True` if `self` is a supersolvable lattice and `False` otherwise.

A lattice L is *supersolvable* if there exists a maximal chain C such that every $x \in C$ is a modular element in L.

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_supersolvable()
True

sage: L = posets.PentagonPoset()
sage: L.is_supersolvable()
False

sage: L = posets.ChainPoset(6)
sage: L.is_supersolvable()
True

sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_supersolvable()
True
sage: L.is_modular()
False

sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [5, 6, 7],
....:                   2: [5, 8, 9], 3: [6, 8, 10], 4: [7, 9, 10],
....:                   5: [11], 6: [11], 7: [11], 8: [11],
....:                   9: [11], 10: [11]})
sage: L.is_supersolvable()
False
```

is_upper_semimodular()

Return `True` if the lattice is upper semimodular and `False` otherwise.

A lattice is upper semimodular if for any x in the lattice that is covered by y and z, both y and z are covered by their join.

See also `is_modular()` and `is_lower_semimodular()`.

See Wikipedia article Semimodular_lattice

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_upper_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_upper_semimodular()
False

sage: L = posets.ChainPoset(6)
sage: L.is_upper_semimodular()
True

sage: L = LatticePoset(posets.IntegerPartitions(4))
sage: L.is_upper_semimodular()
True
```

ALGORITHM:

Based on pp. 286-287 of Enumerative Combinatorics, Vol 1 [EnumComb1].

maximal_sublattices()

Return maximal (proper) sublattices of the lattice.

EXAMPLES:

```
sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],
....:                         [2,5],[2,7],[17,22],[17,13],[8,7],
....:                         [8,13],[3,16],[3,9],[22,16],[22,18],
....:                         [22,10],[5,18],[5,14],[7,9],[7,14],
....:                         [7,10],[13,10],[16,6],[16,19],[9,19],
....:                         [18,6],[18,33],[14,33],[10,19],
....:                         [10,33],[6,4],[19,4],[33,4]] ))
sage: maxs = L.maximal_sublattices()
sage: len(maxs)
7
sage: sorted(maxs[0].list())
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 16, 18, 19, 22, 33]
```

moebius_algebra(*R*)

Return the Möbius algebra of `self` over `R`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field
```

quantum_moebius_algebra(*q=None*)

Return the quantum Möbius algebra of `self` with parameter `q`.

INPUT:

- `q` – (optional) the deformation parameter q

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements
 with q=q over Univariate Laurent Polynomial Ring in q over Integer Ring
```

sublattice(*elms*)

Return the smallest sublattice containing elements on the given list.

INPUT:

- elms – a list of elements of the lattice.

EXAMPLES:

```
sage: L=LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],[2,5],[2,7],[17,22],[17,13],[8,7
sage: L.sublattice([14, 13, 22]).list()
[1, 2, 8, 7, 14, 17, 13, 22, 10, 33]

sage: L = Posets.BooleanLattice(3)
sage: L.sublattice([3,5,6,7])
Finite lattice containing 8 elements
```

Note: This is very unoptimal algorithm. Better one is described on "Computing the sublattice of a lattice generated by a set of elements" by K. Bertet and M. Morvan. Feel free to implement it.

---

class sage.combinat.posets.lattices.**FiniteMeetSemilattice**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: sage.combinat.posets.posets.FinitePoset

Note: We assume that the argument passed to MeetSemilattice is the poset of a meet-semilattice (i.e. a poset with greatest lower bound for each pair of elements).

TESTS:

```
sage: M = MeetSemilattice([[1,2],[3],[3]])
sage: TestSuite(M).run()

sage: P = Poset([[1,2],[3],[3]])
sage: M = MeetSemilattice(P)
sage: TestSuite(M).run()
```

Element

alias of MeetSemilatticeElement

meet(*x*, *y=None*)

Return the meet of given elements in the lattice.

EXAMPLES:

```
sage: D = Posets.DiamondPoset(5)
sage: D.meet(1, 2)
0
sage: D.meet(1, 1)
1
sage: D.meet(1, 0)
0
sage: D.meet(1, 4)
1
```

Using list of elements as an argument. Meet of empty list is the bottom element:

```
sage: B4=Posets.BooleanLattice(4)
sage: B4.meet([3,5,6])
0
sage: B4.meet([])
15
```

Test that this method also works for facade lattices:

```
sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.meet(2, 3)
2
sage: L.meet(1, 2)
0
```

meet_matrix()

Return a matrix whose `(i,j)` entry is `k`, where `self.linear_extension()[k]` is the meet (greatest lower bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

EXAMPLES:

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: M = P.meet_matrix(); M
[0 0 0 0 0 0 0 0]
[0 1 0 1 0 0 0 1]
[0 0 2 2 2 0 2 2]
[0 1 2 3 2 0 2 3]
[0 0 2 2 4 0 2 4]
[0 0 0 0 0 5 5 5]
[0 0 2 2 2 5 6 6]
[0 1 2 3 4 5 6 7]
sage: M[P(4).vertex,P(3).vertex] == P(0).vertex
True
sage: M[P(5).vertex,P(2).vertex] == P(2).vertex
True
sage: M[P(5).vertex,P(2).vertex] == P(5).vertex
False
```

pseudocomplement(*element*)

Return the pseudocomplement of `element`, if it exists.

The pseudocomplement is the greatest element whose meet with given element is the bottom element. I.e. in a meet-semilattice with bottom element $\hat{0}$ the pseudocomplement of an element e is the element $e^\star$ such that $e \wedge e^\star = \hat{0}$ and $e' \leq e^\star$ if $e \wedge e' = \hat{0}$.

See Wikipedia article Pseudocomplement.

INPUT:

- `element` – an element of the lattice.

OUTPUT:

An element of the lattice or `None` if the pseudocomplement does not exist.

EXAMPLES:

The pseudocompelement's pseudocomplement is not always the original element:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: L.pseudocomplement(2)
5
```

```
sage: L.pseudocomplement(5)
4
```

An element can have complements but no pseudocomplement, or vice versa:

```
sage: L = LatticePoset({0: [1, 2], 1: [3, 4, 5], 2: [5], 3: [6],
....:                   4: [6], 5: [6]})
sage: L.complements(1), L.pseudocomplement(1)
([], 2)
sage: L.complements(2), L.pseudocomplement(2)
([3, 4], None)
```

See also:

sage.combinat.posets.lattices.FiniteLatticePoset.is_pseudocomplemented().

TESTS:

```
sage: L = LatticePoset({'a': []})
sage: L.pseudocomplement('a')
'a'
sage: L = LatticePoset({'a': ['b'], 'b': ['c']})
sage: [L.pseudocomplement(e) for e in ['a', 'b', 'c']]
['c', 'a', 'a']
```

sage.combinat.posets.lattices.**JoinSemilattice**(*data*, **args*, ***options*)

Construct a join semi-lattice from various forms of input data.

INPUT:

- data, *args, **options – data and options that will be passed down to Poset() to construct a poset that is also a join semilattice.

See also:

Poset(), MeetSemilattice(), LatticePoset()

EXAMPLES:

Using data that defines a poset:

```
sage: JoinSemilattice([[1,2],[3],[3]])
Finite join-semilattice containing 4 elements

sage: JoinSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite join-semilattice containing 4 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P); J
Finite join-semilattice containing 4 elements
sage: type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: JoinSemilattice((elms, rels))
Traceback (most recent call last):
...
ValueError: Not a join semilattice.
```

sage.combinat.posets.lattices.**LatticePoset**(*data*, **args*, ***options*)

Construct a lattice from various forms of input data.

INPUT:

- `data`, `*args`, `**options` – data and options that will be passed down to `Poset()` to construct a poset that is also a lattice.

OUTPUT:

FiniteLatticePoset – an instance of `FiniteLatticePoset`

See also:

`Posets`, `FiniteLatticePosets`, `JoinSemiLattice()`, `MeetSemiLattice()`

EXAMPLES:

Using data that defines a poset:

```
sage: LatticePoset([[1,2],[3],[3]])
Finite lattice containing 4 elements

sage: LatticePoset([[1,2],[3],[3]], cover_relations = True)
Finite lattice containing 4 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P); L
Finite lattice containing 4 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: LatticePoset((elms, rels))
Traceback (most recent call last):
...
ValueError: Not a lattice.
```

Creating a facade lattice:

```
sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.category()
Join of Category of finite lattice posets and Category of finite enumerated sets and Category of
sage: parent(L[0])
Integer Ring
sage: TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

sage.combinat.posets.lattices.**MeetSemilattice**(*data*, **args*, ***options*)

Construct a meet semi-lattice from various forms of input data.

INPUT:

- `data`, `*args`, `**options` – data and options that will be passed down to `Poset()` to construct a poset that is also a meet semilattice.

See also:

Poset(), JoinSemilattice(), LatticePoset()

EXAMPLES:

Using data that defines a poset:

```
sage: MeetSemilattice([[1,2],[3],[3]])
Finite meet-semilattice containing 4 elements

sage: MeetSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite meet-semilattice containing 4 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = MeetSemilattice(P); L
Finite meet-semilattice containing 4 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: MeetSemilattice((elms, rels))
Traceback (most recent call last):

```

5.1.156 Linear Extensions of Posets

This module defines two classes:

- LinearExtensionOfPoset
- LinearExtensionsOfPoset

Classes and methods

class sage.combinat.posets.linear_extensions.**LinearExtensionOfPoset**

Bases: sage.structure.list_clone.ClonableArray

A linear extension of a finite poset P of size n is a total ordering $\pi := \pi_0\pi_1\ldots\pi_{n-1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset P.

When the elements of P are indexed by $\{1, 2, \ldots, n\}$, π denotes a permutation of the elements of P in one-line notation.

INPUT:

- linear_extension – a list of the elements of P
- poset – the underlying poset P

See also:

Poset, LinearExtensionsOfPoset

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension=True, facade=False)
sage: p = P.linear_extension([1,4,2,3]); p
[1, 4, 2, 3]
sage: p.parent()
The set of all linear extensions of Finite poset containing 4 elements with distinguished linear
sage: p[0], p[1], p[2], p[3]
(1, 4, 2, 3)
```

Following Schützenberger and later Haiman and Malvenuto-Reutenauer, Stanley [Stan2009] defined a promotion and evacuation operator on any finite poset P using operators τ_i on the linear extensions of P:

```
sage: p.promotion()
[1, 2, 3, 4]
sage: Q = p.promotion().to_poset()
sage: Q.cover_relations()
[[1, 3], [1, 4], [2, 3]]
sage: Q == P
True

sage: p.promotion(3)
[1, 4, 2, 3]
sage: Q = p.promotion(3).to_poset()
sage: Q == P
False
sage: Q.cover_relations()
[[1, 2], [1, 4], [3, 4]]
```

check()

Checks whether `self` is indeed a linear extension of the underlying poset.

TESTS:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]))
sage: P.linear_extension([1,4,2,3])
[1, 4, 2, 3]
sage: P.linear_extension([4,3,2,1])
Traceback (most recent call last):
...
ValueError: [4, 3, 2, 1] is not a linear extension of Finite poset containing 4 elements
```

evacuation()

Computes evacuation on the linear extension of a poset.

Evacuation on a linear extension π of length n is defined as $\pi(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$. For more details see [Stan2009].

See also:

`tau()`, `promotion()`

EXAMPLES:

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: p.evacuation()
[1, 4, 2, 3, 7, 5, 6]
sage: p.evacuation().evacuation() == p
True
```

poset()

Returns the underlying original poset.

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,2],[2,3],[1,4]]))
sage: p = P.linear_extension([1,2,4,3])
sage: p.poset()
Finite poset containing 4 elements
```

promotion(*i=1*)

Computes the (generalized) promotion on the linear extension of a poset.

INPUT:

- i – an integer between 1 and $n-1$, where n is the cardinality of the poset (default: 1)

The i-th generalized promotion operator ∂_i on a linear extension π is defined as $\pi\tau_i\tau_{i+1}\cdots\tau_{n-1}$, where n is the size of the linear extension (or size of the underlying poset).

For more details see [Stan2009].

See also:

`tau()`, `evacuation()`

EXAMPLES:

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: q = p.promotion(4); q
[1, 2, 3, 5, 6, 4, 7]
sage: p.to_poset() == q.to_poset()
False
sage: p.to_poset().is_isomorphic(q.to_poset())
True
```

tau(*i*)

Returns the operator τ_i on linear extensions `self` of a poset.

INPUT:

- i – an integer between 1 and $n-1$, where n is the cardinality of the poset.

The operator τ_i on a linear extension π of a poset P interchanges positions i and $i+1$ if the result is again a linear extension of P, and otherwise acts trivially. For more details, see [Stan2009].

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: l = L.an_element(); l
[1, 2, 3, 4]
sage: l.tau(1)
[2, 1, 3, 4]
sage: for p in L:
....:     for i in range(1,4):
....:         print i, p, p.tau(i)
....:
1 [1, 2, 3, 4] [2, 1, 3, 4]
2 [1, 2, 3, 4] [1, 2, 3, 4]
3 [1, 2, 3, 4] [1, 2, 4, 3]
1 [1, 2, 4, 3] [2, 1, 4, 3]
2 [1, 2, 4, 3] [1, 4, 2, 3]
3 [1, 2, 4, 3] [1, 2, 3, 4]
```

```
1 [1, 4, 2, 3] [1, 4, 2, 3]
2 [1, 4, 2, 3] [1, 2, 4, 3]
3 [1, 4, 2, 3] [1, 4, 2, 3]
1 [2, 1, 3, 4] [1, 2, 3, 4]
2 [2, 1, 3, 4] [2, 1, 3, 4]
3 [2, 1, 3, 4] [2, 1, 4, 3]
1 [2, 1, 4, 3] [1, 2, 4, 3]
2 [2, 1, 4, 3] [2, 1, 4, 3]
3 [2, 1, 4, 3] [2, 1, 3, 4]
```

TESTS:

```
sage: type(l.tau(1))
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category.element
sage: l.tau(2) == l
True
```

to_poset()

Return the poset associated to the linear extension `self`.

This method returns the poset obtained from the original poset P by relabelling the i-th element of `self` to the i-th element of the original poset, while keeping the linear extension of the original poset.

For a poset with default linear extension $1, \ldots, n$, `self` can be interpreted as a permutation, and the relabelling is done according to the inverse of this permutation.

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,2],[1,3],[3,4]]), linear_extension=True, facade=False)
sage: p = P.linear_extension([1,3,4,2])
sage: Q = p.to_poset(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: P == Q
False
```

The default linear extension remains the same:

```
sage: list(P)
[1, 2, 3, 4]
sage: list(Q)
[1, 2, 3, 4]
```

But the relabelling can be seen on cover relations:

```
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]

sage: p = P.linear_extension([1,2,3,4])
sage: Q = p.to_poset()
sage: P == Q
True
```

class sage.combinat.posets.linear_extensions.**LinearExtensionsOfPoset**(*poset*, *facade*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The set of all linear extensions of a finite poset

INPUT:

- poset – a poset P of size n
- facade – a boolean (default: False)

See also:

- sage.combinat.posets.posets.FinitePoset.linear_extensions()
- sage.graphs.linearextensions.LinearExtensions

EXAMPLES:

```
sage: elms = [1,2,3,4]
sage: rels = [[1,3],[1,4],[2,3]]
sage: P = Poset((elms, rels), linear_extension=True)
sage: L = P.linear_extensions(); L
The set of all linear extensions of Finite poset containing 4 elements with distinguished linear
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: L.an_element()
[1, 2, 3, 4]
sage: L.poset()
Finite poset containing 4 elements with distinguished linear extension
```

Element
alias of LinearExtensionOfPoset

markov_chain_digraph(*action='promotion'*, *labeling='identity'*)
Returns the digraph of the action of generalized promotion or tau on self

INPUT:

- action – 'promotion' or 'tau' (default: 'promotion')
- labeling – 'identity' or 'source' (default: 'identity')

Todo

- generalize this feature by accepting a family of operators as input
- move up in some appropriate category

This method creates a graph with vertices being the linear extensions of a given finite poset and an edge from π to π' if $\pi' = \pi\partial_i$ where ∂_i is the promotion operator (see promotion()) if action is set to promotion and τ_i (see tau()) if action is set to tau. The label of the edge is i (resp. π_i) if labeling is set to identity (resp. source).

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension = True)
sage: L = P.linear_extensions()
sage: G = L.markov_chain_digraph(); G
Looped multi-digraph on 5 vertices
sage: sorted(G.vertices(), key = repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: sorted(G.edges(), key = repr)
[([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 3, 4], [1, 2, 4,
([1, 2, 3, 4], [2, 1, 4, 3], 1), ([1, 2, 4, 3], [1, 2, 3, 4], 3), ([1, 2, 4, 3], [1, 2, 4, 3
```

```
([1, 2, 4, 3], [1, 4, 2, 3], 2), ([1, 2, 4, 3], [2, 1, 3, 4], 1), ([1, 4, 2, 3], [1, 2, 3, 4
([1, 4, 2, 3], [1, 2, 3, 4], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([1, 4, 2, 3], [1, 4, 2, 3
([2, 1, 3, 4], [1, 2, 4, 3], 1), ([2, 1, 3, 4], [2, 1, 3, 4], 4), ([2, 1, 3, 4], [2, 1, 4, 3
([2, 1, 3, 4], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [1, 4, 2, 3], 1), ([2, 1, 4, 3], [2, 1, 3, 4
([2, 1, 4, 3], [2, 1, 3, 4], 3), ([2, 1, 4, 3], [2, 1, 4, 3], 4)]

sage: G = L.markov_chain_digraph(labeling = 'source')
sage: sorted(G.vertices(), key = repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: sorted(G.edges(), key = repr)
[([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 3, 4], [1, 2, 4,
([1, 2, 3, 4], [2, 1, 4, 3], 1), ([1, 2, 4, 3], [1, 2, 3, 4], 4), ([1, 2, 4, 3], [1, 2, 4, 3
([1, 2, 4, 3], [1, 4, 2, 3], 2), ([1, 2, 4, 3], [2, 1, 3, 4], 1), ([1, 4, 2, 3], [1, 2, 3, 4
([1, 4, 2, 3], [1, 2, 3, 4], 4), ([1, 4, 2, 3], [1, 4, 2, 3], 2), ([1, 4, 2, 3], [1, 4, 2, 3
([2, 1, 3, 4], [1, 2, 4, 3], 2), ([2, 1, 3, 4], [2, 1, 3, 4], 4), ([2, 1, 3, 4], [2, 1, 4, 3
([2, 1, 3, 4], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [1, 4, 2, 3], 2), ([2, 1, 4, 3], [2, 1, 3, 4
([2, 1, 4, 3], [2, 1, 3, 4], 4), ([2, 1, 4, 3], [2, 1, 4, 3], 3)]
```

The edges of the graph are by default colored using blue for edge 1, red for edge 2, green for edge 3, and yellow for edge 4:

```
sage: view(G) # optional - dot2tex graphviz, not tested (opens external window)
```

Alternatively, one may get the graph of the action of the `tau` operator:

```
sage: G = L.markov_chain_digraph(action='tau'); G
Looped multi-digraph on 5 vertices
sage: sorted(G.vertices(), key = repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: sorted(G.edges(), key = repr)
[([1, 2, 3, 4], [1, 2, 3, 4], 2), ([1, 2, 3, 4], [1, 2, 4, 3], 3), ([1, 2, 3, 4], [2, 1, 3,
([1, 2, 4, 3], [1, 2, 3, 4], 3), ([1, 2, 4, 3], [1, 4, 2, 3], 2), ([1, 2, 4, 3], [2, 1, 4, 3
([1, 4, 2, 3], [1, 2, 4, 3], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 1), ([1, 4, 2, 3], [1, 4, 2, 3
([2, 1, 3, 4], [1, 2, 3, 4], 1), ([2, 1, 3, 4], [2, 1, 3, 4], 2), ([2, 1, 3, 4], [2, 1, 4, 3
([2, 1, 4, 3], [1, 2, 4, 3], 1), ([2, 1, 4, 3], [2, 1, 3, 4], 3), ([2, 1, 4, 3], [2, 1, 4, 3
sage: view(G) # optional - dot2tex graphviz, not tested (opens external window)
```

See also:

`markov_chain_transition_matrix()`, `promotion()`, `tau()`

TESTS:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension = True, facade = True)
sage: L = P.linear_extensions()
sage: G = L.markov_chain_digraph(labeling = 'source'); G
Looped multi-digraph on 5 vertices
```

markov_chain_transition_matrix(*action='promotion'*, *labeling='identity'*)

Returns the transition matrix of the Markov chain for the action of generalized promotion or tau on `self`

INPUT:

- `action` – 'promotion' or 'tau' (default: 'promotion')
- `labeling` – 'identity' or 'source' (default: 'identity')

This method yields the transition matrix of the Markov chain defined by the action of the generalized promotion operator ∂_i (resp. τ_i) on the set of linear extensions of a finite poset. Here the transition from the linear extension π to π', where $\pi' = \pi\partial_i$ (resp. $\pi' = \pi\tau_i$) is counted with weight x_i (resp. x_{π_i} if `labeling` is set to `source`).

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension = True)
sage: L = P.linear_extensions()
sage: L.markov_chain_transition_matrix()
[-x0 - x1 - x2            x2       x0 + x1             0             0]
[      x1 + x2 -x0 - x1 - x2             0            x0             0]
[            0            x1      -x0 - x1             0            x0]
[            0            x0             0 -x0 - x1 - x2       x1 + x2]
[           x0             0             0       x1 + x2 -x0 - x1 - x2]

sage: L.markov_chain_transition_matrix(labeling = 'source')
[-x0 - x1 - x2            x3       x0 + x3             0             0]
[      x1 + x2 -x0 - x1 - x3             0            x1             0]
[            0            x1      -x0 - x3             0            x1]
[            0            x0             0 -x0 - x1 - x2       x0 + x3]
[           x0             0             0       x0 + x2 -x0 - x1 - x3]

sage: L.markov_chain_transition_matrix(action = 'tau')
[     -x0 - x2            x2             0            x0             0]
[           x2 -x0 - x1 - x2            x1             0            x0]
[            0            x1           -x1             0             0]
[           x0             0             0      -x0 - x2            x2]
[            0            x0             0            x2      -x0 - x2]

sage: L.markov_chain_transition_matrix(action = 'tau', labeling = 'source')
[     -x0 - x2            x3             0            x1             0]
[           x2 -x0 - x1 - x3            x3             0            x1]
[            0            x1           -x3             0             0]
[           x0             0             0      -x1 - x2            x3]
[            0            x0             0            x2      -x1 - x3]
```

See also:

markov_chain_digraph(),promotion(),tau()

poset()

Returns the underlying original poset.

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,2],[2,3],[1,4]]))
sage: L = P.linear_extensions()
sage: L.poset()
Finite poset containing 4 elements
```

5.1.157 Möbius Algebras

class sage.combinat.posets.moebius_algebra.**BasisAbstract**(*R*, *basis_keys*, *element_class=None*, *category=None*, *prefix='B'*, ***kwds*)

Bases: sage.combinat.free_module.CombinatorialFreeModule, sage.misc.bindable_class.BindableClass

Abstract base class for a basis.

class sage.combinat.posets.moebius_algebra.**MoebiusAlgebra**(*R*, *L*)

Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresenta

The Möbius algebra of a lattice.

Let L be a lattice. The *Möbius algebra* M_L was originally constructed by Solomon and has a natural basis $\{E_x \mid x \in L\}$ with multiplication given by $E_x \cdot E_y = E_{x \vee y}$. Moreover this has a basis given by orthogonal idempotents $\{I_x \mid x \in L\}$ (so $I_x I_y = \delta_{xy} I_x$ where δ is the Kronecker delta) related to the natural basis by

$$I_x = \sum_{y \leq x} \mu_L(y, x) E_x,$$

where μ_L is the Möbius function of L.

REFERENCES:

class **E**(*M*, *prefix='E'*)

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The natural basis of a Möbius algebra.

Let E_x and E_y be basis elements of M_L for some lattice L. Multiplication is given by $E_x E_y = E_{x \vee y}$.

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.one()
E[0]
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
E[10]
```

class MoebiusAlgebra.**I**(*M*, *prefix='I'*)

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The (orthogonal) idempotent basis of a Möbius algebra.

Let I_x and I_y be basis elements of M_L for some lattice L. Multiplication is given by $I_x I_y = \delta_{xy} I_x$ where δ_{xy} is the Kronecker delta.

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.one()
I[0] + I[1] + I[2] + I[3] + I[4] + I[5] + I[6] + I[7] + I[8]
 + I[9] + I[10] + I[11] + I[12] + I[13] + I[14] + I[15]
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.product_on_basis(5, 14)
0
sage: I.product_on_basis(2, 2)
I[2]
```

MoebiusAlgebra.**a_realization**()

Return a particular realization of `self` (the B-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.a_realization()
Moebius algebra of Finite lattice containing 16 elements
 over Rational Field in the natural basis
```

MoebiusAlgebra.**lattice**()

Return the defining lattice of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

class sage.combinat.posets.moebius_algebra.**MoebiusAlgebraBases**(*parent_with_realization*)

Bases: sage.categories.realizations.Category_realization_of_parent

The category of bases of a Möbius algebra.

INPUT:

- `base` – a Möbius algebra

TESTS:

```
sage: from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
sage: M = posets.BooleanLattice(4).moebius_algebra(QQ)
sage: bases = MoebiusAlgebraBases(M)
sage: M.E() in bases
True
```

class ElementMethods

class MoebiusAlgebraBases.**ParentMethods**

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: all(C.one() * b == b for b in C.basis())
True
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: C.product_on_basis(5, 14)
q^3*C[15]
sage: C.product_on_basis(2, 8)
q^4*C[10]
```

MoebiusAlgebraBases.**super_categories**()

The super categories of `self`.

EXAMPLES:

```
sage: from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
sage: M = posets.BooleanLattice(4).moebius_algebra(QQ)
sage: bases = MoebiusAlgebraBases(M)
sage: bases.super_categories()
[Category of finite dimensional commutative algebras with basis over Rational Field,
 Category of realizations of Moebius algebra of Finite lattice
    containing 16 elements over Rational Field]
```

class sage.combinat.posets.moebius_algebra.**QuantumMoebiusAlgebra**(*L*, *q=None*)

Bases: sage.structure.parent.Parent, sage.structure.unique_representation.UniqueRepresenta

The quantum Möbius algebra of a lattice.

Let L be a lattice, and we define the *quantum Möbius algebra* $M_L(q)$ as the algebra with basis $\{E_x \mid x \in L\}$ with multiplication given by

$$E_x E_y = \sum_{z \geq a \geq x \vee y} \mu_L(a, z) q^{\operatorname{crk} a} E_z,$$

where μ_L is the Möbius function of L and crk is the corank function (i.e., $\operatorname{crk} a = \operatorname{rank} L - \operatorname{rank}$ a). At $q = 1$, this reduces to the multiplication formula originally given by Solomon.

class C(*M*, *prefix='C'*)

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The characteristic basis of a quantum Möbius algebra.

The characteristic basis $\{C_x \mid x \in L\}$ of M_L for some lattice L is defined by

$$C_x = \sum_{a \geq x} P(F^x; q) E_a,$$

where $F^x = \{y \in L \mid y \geq x\}$ is the principal order filter of x and $P(F^x; q)$ is the characteristic polynomial of the (sub)poset F^x.

class QuantumMoebiusAlgebra.**E**(*M*, *prefix='E'*)

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The natural basis of a quantum Möbius algebra.

Let E_x and E_y be basis elements of M_L for some lattice L. Multiplication is given by

$$E_x E_y = \sum_{z \geq a \geq x \vee y} \mu_L(a, z) q^{\operatorname{crk} a} E_z,$$

where μ_L is the Möbius function of L and crk is the corank function (i.e., $\operatorname{crk} a = \operatorname{rank} L - \operatorname{rank}$ a).

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: all(E.one() * b == b for b in E.basis())
True
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
q^2*E[10] + (q-q^2)*E[11] + (q-q^2)*E[14] + (1-2*q+q^2)*E[15]
```

class QuantumMoebiusAlgebra.**KL**(*M*, *prefix='KL'*)

Bases: sage.combinat.posets.moebius_algebra.BasisAbstract

The Kazhdan-Lusztig basis of a quantum Möbius algebra.

The Kazhdan-Lusztig basis $\{B_x \mid x \in L\}$ of M_L for some lattice L is defined by

$$B_x = \sum_{y \geq x} P_{x,y}(q) E_a,$$

where $P_{x,y}(q)$ is the Kazhdan-Lusztig polynomial of L, following the definition given in [EPW14].

EXAMPLES:

We construct some examples of Proposition 4.5 of [EPW14]:

```
sage: M = posets.BooleanLattice(4).quantum_moebius_algebra()
sage: KL = M.KL()
sage: KL[4] * KL[5]
(q^2+q^3)*KL[5] + (q+2*q^2+q^3)*KL[7] + (q+2*q^2+q^3)*KL[13]
 + (1+3*q+3*q^2+q^3)*KL[15]
sage: KL[4] * KL[15]
(1+3*q+3*q^2+q^3)*KL[15]
sage: KL[4] * KL[10]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
```

QuantumMoebiusAlgebra.**a_realization**()

Return a particular realization of `self` (the B-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.a_realization()
Quantum Moebius algebra of Finite lattice containing 16 elements
 with q=q over Univariate Laurent Polynomial Ring in q
 over Integer Ring in the natural basis
```

QuantumMoebiusAlgebra.**lattice**()

Return the defining lattice of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.lattice()
```

```
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

5.1.158 A catalog of posets and lattices.

Some common posets can be accessed through the `posets.<tab>` object:

```
sage: posets.PentagonPoset()
Finite lattice containing 5 elements
```

Moreover, the set of all posets of order n is represented by `Posets(n)`:

```
sage: Posets(5)
Posets containing 5 vertices
```

Catalog of common posets:

`AntichainPoset()`	Return an antichain on n elements.
`BooleanLattice()`	Return the Boolean lattice on 2^n elements.
`ChainPoset()`	Return a chain on n elements.
`DiamondPoset()`	Return the lattice of rank two on n elements.
`IntegerCompositions()`	Return the poset of integer compositions of n.
`IntegerPartitions()`	Return the poset of integer partitions of `n`.
`PentagonPoset()`	Return the Pentagon poset.
`RandomPoset()`	Return a random poset on n vertices according to a probability p.
`RestrictedIntegerPartitions()`	Return the poset of integer partitions of n, ordered by restricted refinement.
`ShardPoset()`	Return the shard intersection order.
`SSTPoset()`	Return the poset on semistandard tableaux of shape s and largest entry f that is ordered by componentwise comparison.
`StandardExample()`	Return the standard example of a poset with dimension n.
`SymmetricGroupBruhatIntervalPoset()`	The poset of permutations with respect to Bruhat order.
`SymmetricGroupBruhatOrderPoset()`	The poset of permutations with respect to Bruhat order.
`SymmetricGroupWeakOrderPoset()`	The poset of permutations of $\{1, 2, \ldots, n\}$ with respect to the weak order.
`TamariLattice()`	Return the Tamari lattice.
`TetrahedralPoset()`	Return the Tetrahedral poset with $n - 1$ layers based on the input colors.

Constructions

class `sage.combinat.posets.poset_examples.`**`Posets`**

Bases: `object`

A collection of posets and lattices.

EXAMPLES:

```
sage: Posets.BooleanLattice(3)
Finite lattice containing 8 elements
sage: Posets.ChainPoset(3)
Finite lattice containing 3 elements
sage: Posets.RandomPoset(17,.15)
Finite poset containing 17 elements
```

The category of all posets:

```
sage: Posets()
Category of posets
```

The enumerated set of all posets on 3 vertices, up to an isomorphism:

```
sage: Posets(3)
Posets containing 3 vertices
```

See also:

`Posets`, `FinitePosets`, `Poset()`

TESTS:

```
sage: P = Posets
sage: TestSuite(P).run()
```

static `AntichainPoset` (n)

Returns an antichain (a poset with no comparable elements) containing n elements.

EXAMPLES:

```
sage: A = Posets.AntichainPoset(6); A
Finite poset containing 6 elements
sage: for i in range(5):
...       for j in range(5):
...           if A.covers(A(i),A(j)):
...              print "TEST FAILED"
```

TESTS:

Check that trac ticket #8422 is solved:

```
sage: Posets.AntichainPoset(0)
Finite poset containing 0 elements
sage: C = Posets.AntichainPoset(1); C
Finite poset containing 1 elements
sage: C.cover_relations()
[]
sage: C = Posets.AntichainPoset(2); C
Finite poset containing 2 elements
sage: C.cover_relations()
[]
```

static `BooleanLattice` (n)

Returns the Boolean lattice containing 2^n elements.

EXAMPLES:

```
sage: Posets.BooleanLattice(5)
Finite lattice containing 32 elements
```

static `ChainPoset` (n)

Returns a chain (a totally ordered poset) containing `n` elements.

EXAMPLES:

```
sage: C = Posets.ChainPoset(6); C
Finite lattice containing 6 elements
sage: C.linear_extension()
[0, 1, 2, 3, 4, 5]
sage: for i in range(5):
```

```
...       for j in range(5):
...           if C.covers(C(i),C(j)) and j != i+1:
...              print "TEST FAILED"
```

TESTS:

Check that trac ticket #8422 is solved:

```
sage: Posets.ChainPoset(0)
Finite lattice containing 0 elements
sage: C = Posets.ChainPoset(1); C
Finite lattice containing 1 elements
sage: C.cover_relations()
[]
sage: C = Posets.ChainPoset(2); C
Finite lattice containing 2 elements
sage: C.cover_relations()
[[0, 1]]
```

static DiamondPoset(*n*, *facade=None*)

Return the lattice of rank two containing `n` elements.

INPUT:

- `n` - number of vertices, an integer at least 3.
- `facade` (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`). The default behaviour is the same as the default behaviour of the `Poset()` constructor).

EXAMPLES:

```
sage: Posets.DiamondPoset(7)
Finite lattice containing 7 elements
```

static IntegerCompositions(*n*)

Returns the poset of integer compositions of the integer `n`.

A composition of a positive integer n is a list of positive integers that sum to n. The order is reverse refinement: $[p_1, p_2, ..., p_l] < [q_1, q_2, ..., q_m]$ if q consists of an integer composition of p_1, followed by an integer composition of p_2, and so on.

EXAMPLES:

```
sage: P = Posets.IntegerCompositions(7); P
Finite poset containing 64 elements
sage: len(P.cover_relations())
192
```

static IntegerPartitions(*n*)

Returns the poset of integer partitions on the integer `n`.

A partition of a positive integer n is a non-increasing list of positive integers that sum to n. If p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two parts of p (and sorting, if necessary).

EXAMPLES:

```
sage: P = Posets.IntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
28
```

static PentagonPoset (*facade=None*)

Returns the Pentagon poset.

INPUT:

- facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets). The default behaviour is the same as the default behaviour of the Poset() constructor).

EXAMPLES:

```
sage: P = Posets.PentagonPoset(); P
Finite lattice containing 5 elements
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```

This is smallest lattice that is not modular:

```
sage: P.is_modular()
False
```

This poset and the DiamondPoset() are the two smallest lattices which are not distributive:

```
sage: P.is_distributive()
False
sage: Posets.DiamondPoset(5).is_distributive()
False
```

static RandomPoset (*n*, *p*)

Generate a random poset on n vertices according to a probability p.

INPUT:

- n - number of vertices, a non-negative integer
- p - a probability, a real number between 0 and 1 (inclusive)

OUTPUT:

A poset on n vertices. The construction decides to make an ordered pair of vertices comparable in the poset with probability p, however a pair is not made comparable if it would violate the defining properties of a poset, such as transitivity.

So in practice, once the probability exceeds a small number the generated posets may be very similar to a chain. So to create interesting examples, keep the probability small, perhaps on the order of $1/n$.

EXAMPLES:

```
sage: Posets.RandomPoset(17,.15)
Finite poset containing 17 elements
```

TESTS:

```
sage: Posets.RandomPoset('junk', 0.5)
Traceback (most recent call last):
...
TypeError: number of elements must be an integer, not junk

sage: Posets.RandomPoset(-6, 0.5)
Traceback (most recent call last):
...
ValueError: number of elements must be non-negative, not -6

sage: Posets.RandomPoset(6, 'garbage')
```

```
Traceback (most recent call last):
...
TypeError: probability must be a real number, not garbage

sage: Posets.RandomPoset(6, -0.5)
Traceback (most recent call last):
...
ValueError: probability must be between 0 and 1, not -0.5
```

static RestrictedIntegerPartitions(*n*)

Returns the poset of integer partitions on the integer n ordered by restricted refinement. That is, if p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two distinct parts of p (and sorting, if necessary).

EXAMPLES:

```
sage: P = Posets.RestrictedIntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
17
```

static SSTPoset(*s*, *f=None*)

The poset on semistandard tableaux of shape `s` and largest entry `f` that is ordered by componentwise comparison of the entries.

INPUT:

- `s` - shape of the tableaux
- `f` - maximum fill number. This is an optional argument. If no maximal number is given, it will use the number of cells in the shape.

NOTE: This is a basic implementation and most certainly not the most efficient.

EXAMPLES:

```
sage: Posets.SSTPoset([2,1])
Finite poset containing 8 elements

sage: Posets.SSTPoset([2,1],4)
Finite poset containing 20 elements

sage: Posets.SSTPoset([2,1],2).cover_relations()
[[[[1, 1], [2]], [[1, 2], [2]]]]

sage: Posets.SSTPoset([3,2]).bottom()  # long time (6s on sage.math, 2012)
[[1, 1, 1], [2, 2]]

sage: Posets.SSTPoset([3,2],4).maximal_elements()
[[[3, 3, 4], [4, 4]]]
```

static ShardPoset(*n*)

Return the shard intersection order on permutations of size n.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension n. The shard poset is given by the inclusion of these cones.

See also:

`shard_preorder_graph()`

EXAMPLES:

```
sage: P = posets.ShardPoset(4); P  # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_selfdual()
False
```

static `StandardExample`(*n*, *facade=None*)

Return the partially ordered set on `2n` elements with dimension `n`.

Let P be the poset on $\{0, 1, 2, \ldots, 2n-1\}$ whose defining relations are that $i < j$ for every $0 \leq i < n \leq j < 2n$ except when $i + n = j$. The poset P is the so-called *standard example* of a poset with dimension n.

INPUT:

- `n` – an integer ≥ 2, dimension of the constructed poset
- `facade` (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the `Poset()` constructor

OUTPUT:

The standard example of a poset of dimension n.

EXAMPLES:

```
sage: A = Posets.StandardExample(3); A
Finite poset containing 6 elements
sage: A.dimension()
3
```

REFERENCES:

TESTS:

```
sage: A = Posets.StandardExample(10); A
Finite poset containing 20 elements
sage: len(A.cover_relations())
90

sage: P = Posets.StandardExample(5, facade=False)
sage: P(4) < P(3), P(4) > P(3)
(False, False)
```

static `SymmetricGroupBruhatIntervalPoset`(*start*, *end*)

The poset of permutations with respect to Bruhat order.

INPUT:

- `start` - list permutation
- `end` - list permutation (same n, of course)

Note: Must have `start` <= `end`.

EXAMPLES:

Any interval is rank symmetric if and only if it avoids these permutations:

```
sage: P1 = Posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [3,4,1,2])
sage: P2 = Posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [4,2,3,1])
sage: ranks1 = [P1.rank(v) for v in P1]
sage: ranks2 = [P2.rank(v) for v in P2]
sage: [ranks1.count(i) for i in uniq(ranks1)]
[1, 3, 5, 4, 1]
sage: [ranks2.count(i) for i in uniq(ranks2)]
[1, 3, 5, 6, 4, 1]
```

static SymmetricGroupBruhatOrderPoset(n)

The poset of permutations with respect to Bruhat order.

EXAMPLES:

```
sage: Posets.SymmetricGroupBruhatOrderPoset(4)
Finite poset containing 24 elements
```

static SymmetricGroupWeakOrderPoset(n, *labels='permutations'*, *side='right'*)

The poset of permutations of $\{1, 2, \ldots, n\}$ with respect to the weak order (also known as the permutohedron order, cf. `permutohedron_lequal()`).

The optional variable `labels` (default: `"permutations"`) determines the labelling of the elements if $n < 10$. The optional variable `side` (default: `"right"`) determines whether the right or the left permutohedron order is to be used.

EXAMPLES:

```
sage: Posets.SymmetricGroupWeakOrderPoset(4)
Finite poset containing 24 elements
```

static TamariLattice(n)

Return the n-th Tamari lattice.

INPUT:

- n a nonnegative integer

OUTPUT:

- a finite lattice

The elements of the lattice are `Dyck paths` in the $(n+1 \times n)$-rectangle.

See Tamari lattice for mathematical background.

EXAMPLES:

```
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements
```

static TetrahedralPoset(n, **colors*, ***labels*)

Return the tetrahedral poset based on the input colors.

This method will return the tetrahedral poset with n-1 layers and covering relations based on the input colors of 'green', 'red', 'orange', 'silver', 'yellow' and 'blue' as defined in [Striker2011]. For particular color choices, the order ideals of the resulting tetrahedral poset will be isomorphic to known combinatorial objects.

For example, for the colors 'blue', 'yellow', 'orange', and 'green', the order ideals will be in bijection with alternating sign matrices. For the colors 'yellow', 'orange', and 'green', the order ideals will be in bijection with semistandard Young tableaux of staircase shape. For the colors 'red', 'orange', 'green', and optionally 'yellow', the order ideals will be in bijection with totally symmetric self-complementary plane partitions in a $2n \times 2n \times 2n$ box.

INPUT:

- `n` - Defines the number (n-1) of layers in the poset.
- `colors` - The colors that define the covering relations of the poset. Colors used are 'green', 'red', 'yellow', 'orange', 'silver', and 'blue'.
- `labels` - Keyword variable used to determine whether the poset is labeled with integers or tuples. To label with integers, the method should be called with `labels='integers'`. Otherwise, the labeling will default to tuples.

EXAMPLES:

```
sage: Posets.TetrahedralPoset(4,'green','red','yellow','silver','blue','orange')
Finite poset containing 10 elements

sage: Posets.TetrahedralPoset(4,'green','red','yellow','silver','blue','orange', labels='int
Finite poset containing 10 elements

sage: A = AlternatingSignMatrices(3)
sage: p = A.lattice()
sage: ji = p.join_irreducibles_poset()
sage: tet = Posets.TetrahedralPoset(3, 'green','yellow','blue','orange')
sage: ji.is_isomorphic(tet)
True
```

`sage.combinat.posets.poset_examples.`**`posets`**
alias of `Posets`

5.1.159 Finite posets

This module implements finite partially ordered sets. It defines:

`FinitePoset`	A class for finite posets
`FinitePosets_n`	A class for finite posets up to isomorphism (i.e. unlabeled posets)
`Poset()`	Construct a finite poset from various forms of input data.
`is_poset()`	Return `True` if a directed graph is acyclic and transitively reduced.

List of Poset methods

Comparing, intervals and relations

is_less_than()	Return True if x is strictly less than y in the poset.
is_greater_than()	Return True if x is strictly greater than y in the poset.
is_lequal()	Return True if x is less than or equal to y in the poset.
is_gequal()	Return True if x is greater than or equal to y in the poset.
compare_elements()	Compare two element of the poset.
closed_interval()	Return the list of elements in a closed interval of the poset.
open_interval()	Return the list of elements in an open interval of the poset.
relations()	Return the list of relations in the poset.
relations_iterator()	Return an iterator over relations in the poset.
order_filter()	Return the upper set generated by elements.
order_ideal()	Return the lower set generated by elements.

Covering

covers()	Return True if y covers x.
lower_covers()	Return elements covered by given element.
upper_covers()	Return elements covering given element.
cover_relations()	Return the list of cover relations.
lower_covers_iterator()	Return an iterator over elements covered by given element.
upper_covers_iterator()	Return an iterator over elements covering given element.
cover_relations_iterator()	Return an iterator over cover relations of the poset.

Properties of the poset

cardinality()	Return the number of elements in the poset.
height()	Return the number of elements in a longest chain of the poset.
width()	Return the number of elements in a longest antichain of the poset.
relations_number()	Return the number of relations in the poset.
dimension()	Return the dimension of the poset.
has_bottom()	Return True if the poset has a unique minimal element.
has_top()	Return True if the poset has a unique maximal element.
is_bounded()	Return True if the poset has both unique minimal and unique maximal element.
is_chain()	Return True if the poset is totally ordered.
is_connected()	Return True if the poset is connected.
is_graded()	Return True if all maximal chains of the poset has same length.
is_ranked()	Return True if the poset has a rank function.
is_rank_symmetric()	Return True if the poset is rank symmetric.
is_eulerian()	Return True if the poset is Eulerian.
is_incomparable_chain_free()	Return True if the poset is (m+n)-free.
is_slender()	Return True if the poset is slender.
is_join_semilattice()	Return True is the poset has a join operation.
is_meet_semilattice()	Return True if the poset has a meet operation.

Minimal and maximal elements

bottom()	Return the bottom element of the poset, if it exists.
top()	Return the top element of the poset, if it exists.
maximal_elements()	Return the list of the maximal elements of the poset.
minimal_elements()	Return the list of the minimal elements of the poset.

New posets from old ones

disjoint_union()	Return the disjoint union of the poset with other poset.
ordinal_sum()	Return the ordinal sum of the poset with other poset.
ordinal_product()	Return the ordinal product of the poset with other poset.
product()	Return the Cartesian product of the poset with other poset.
with_bounds()	Return the poset with bottom and top element adjoined.
dual()	Return the dual poset of this poset.
completion_by_cuts()	Return the Dedekind-MacNeille completion of the poset.
connected_components()	Return the connected components of the poset as subposets.
ordinal_summands()	Return the ordinal summands of the poset.
subposet()	Return the subposet containing elements with partial order induced by this poset.
random_subposet()	Return a random subposet that contains each element with given probability.
canonical_label()	Return copy of the poset canonically (re)labelled with elements $\{0, \ldots, n-1\}$.
relabel()	Return a copy of this poset with its elements relabelled.

Chains & antichains

is_chain_of_poset()	Return `True` if the given list is a chain of the poset.
chains()	Return the chains of the poset.
antichains()	Return the antichains of the poset.
maximal_chains()	Return the maximal chains of the poset.
maximal_antichains()	Return the maximal antichains of the poset.
antichains_iterator()	Return an iterator over the antichains of the poset.

Drawing

show()	Display the Hasse diagram of the poset.
plot()	Return a Graphic object corresponding the Hasse diagram of the poset.
graphviz_string()	Return a representation in the DOT language, ready to render in graphviz.

Comparing posets

is_isomorphic()	Return `True` if both posets are isomorphic.
is_induced_subposet()	Return `True` if given poset is an induced subposet of this poset.

Polynomials

chain_polynomial()	Return the chain polynomial of the poset.
characteristic_polynomial()	Return the characteristic polynomial of the poset.
f_polynomial()	Return the f-polynomial of a bounded poset.
flag_f_polynomial()	Return the flag f-polynomial of a bounded and ranked poset.
flag_h_polynomial()	Return the flag h-polynomial of a bounded and ranked poset.
h_polynomial()	Return the h-polynomial of a bounded poset.
kazhdan_lusztig_polynomial()	Return the Kazhdan-Lusztig polynomial $P_{x,y}(q)$ of `self`.
order_polynomial()	Return the order polynomial of the poset.
zeta_polynomial()	Return the zeta polynomial of the poset.

Polytopes

chain_polytope()	Return the chain polytope of the poset.
order_polytope()	Return the order polytope of the poset.

Graphs

hasse_diagram()	Return the Hasse diagram of the poset as a directed graph.
cover_relations_graph()	Return the (undirected) graph of cover relations.
comparability_graph()	Return the comparability graph of the poset.
incomparability_graph()	Return the incomparability graph of the poset.
linear_extensions_graph()	Return the linear extensions graph of the poset.

Other & not yet classified

isomorphic_subposets()	Return all subposets isomorphic to another poset.
isomorphic_subposets_iterator()	Return an iterator over the subposets isomorphic to another poset.
has_isomorphic_subposet()	Return True if the poset contains a subposet isomorphic to another poset.
moebius_function()	Return the value of Möbius function of given elements in the poset.
moebius_function_matrix()	Return a matrix whose (i, j) entry is the value of the Möbius function evaluated at
is_linear_extension()	Return whether l is a linear extension of self.
linear_extension()	Return a linear extension of this poset.
linear_extensions()	Return the enumerated set of all the linear extensions of this poset.
promotion()	Computes the (extended) promotion on the linear extension of the poset.
evacuation()	Computes evacuation on the linear extension associated to the poset.
coxeter_transformation()	Return the matrix of the Auslander-Reiten translation acting on the Grothendieck gro
coxeter_polynomial()	Return the characteristic polynomial of the Coxeter transformation.
list()	List the elements of the poset.
cuts()	Return the cuts of the given poset.
dilworth_decomposition()	Return a partition of the points into the minimal number of chains.
frank_network()	Return Frank's network (a DiGraph along with a cost function on its edges) associat
greene_shape()	Computes the Greene-Kleitman partition aka Greene shape of the poset self.
incidence_algebra()	Return the indicence algebra of self.
is_EL_labelling()	Return whether f is an EL labelling of the poset.
is_linear_extension()	Return whether l is a linear extension of self.
isomorphic_subposets_iterator()	Return an iterator over the subposets isomorphic to another poset.
isomorphic_subposets()	Return all subposets isomorphic to another poset.
lequal_matrix()	Computes the matrix whose (i, j) entry is 1 if self.linear_extension()[
level_sets()	Return a list l such that l[i+1] is the set of minimal elements of the poset obtained by
order_complex()	Return the order complex associated to this poset.
p_partition_enumerator()	Return a P-partition enumerator of the poset.
random_order_ideal()	Return a random order ideal of self with uniform probability.
rank()	Return the rank of an element, or the rank of the poset.
rank_function()	Return a rank function of the poset, if it exists.
unwrap()	Unwraps an element of this poset.
with_linear_extension()	Return a copy of self with a different default linear extension.

Classes and functions

class sage.combinat.posets.posets.**FinitePoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A (finite) n-element poset constructed from a directed acyclic graph.

INPUT:

- hasse_diagram – an instance of FinitePoset, or a DiGraph that is transitively-reduced, acyclic, loop-free, and multiedge-free.
- elements – an optional list of elements, with element[i] corresponding to vertex i. If elements is None, then it is set to be the vertex set of the digraph. Note that if this option is set, then elements is considered as a specified linear extension of the poset and the $linear_extension$ attribute is set.
- category – FinitePosets, or a subcategory thereof.
- facade – a boolean or None (default); whether the FinitePoset's elements should be wrapped to make them aware of the Poset they belong to.

– If `facade = True`, the `FinitePoset`'s elements are exactly those given as input.

– If `facade = False`, the `FinitePoset`'s elements will become `PosetElement` objects.

– If `facade = None` (default) the expected behaviour is the behaviour of `facade = True`, unless the opposite can be deduced from the context (i.e. for instance if a `FinitePoset` is built from another `FinitePoset`, itself built with `facade = False`)

• `key` – any hashable value (default: `None`).

EXAMPLES:

```
sage: uc = [[2,3], [], [1], [1], [1], [3,4]]
sage: from sage.combinat.posets.posets import FinitePoset
sage: P = FinitePoset(DiGraph(dict([[i,uc[i]] for i in range(len(uc))])), facade=False); P
Finite poset containing 6 elements
sage: P.cover_relations()
[[5, 4], [5, 3], [4, 1], [0, 2], [0, 3], [2, 1], [3, 1]]
sage: TestSuite(P).run()
sage: P.category()
Join of Category of finite posets and Category of finite enumerated sets
sage: P.__class__
<class 'sage.combinat.posets.posets.FinitePoset_with_category'>

sage: Q = sage.combinat.posets.posets.FinitePoset(P, facade = False); Q
Finite poset containing 6 elements

sage: Q is P
True
```

We keep the same underlying Hasse diagram, but change the elements:

```
sage: Q = sage.combinat.posets.posets.FinitePoset(P, elements=[1,2,3,4,5,6], facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]
```

We test the facade argument:

```
sage: P = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=False)
sage: P.category()
Join of Category of finite posets and Category of finite enumerated sets
sage: parent(P[0]) is P
True

sage: Q = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=True)
sage: Q.category()
Join of Category of finite posets
    and Category of finite enumerated sets
    and Category of facade sets
sage: parent(Q[0]) is str
True
sage: TestSuite(Q).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

Changing a non facade poset to a facade poset:

```
sage: PQ = Poset(P, facade=True)
sage: PQ.category()
Join of Category of finite posets
    and Category of finite enumerated sets
    and Category of facade sets
sage: parent(PQ[0]) is str
```

```
True
sage: PQ is Q
True
```

Changing a facade poset to a non facade poset:

```
sage: QP = Poset(Q, facade = False)
sage: QP.category()
Join of Category of finite posets
    and Category of finite enumerated sets
sage: parent(QP[0]) is QP
True
```

Note: A class that inherits from this class needs to define `Element`. This is the class of the elements that the inheriting class contains. For example, for this class, `FinitePoset`, `Element` is `PosetElement`. It can also define `_dual_class` which is the class of dual posets of this class. E.g. `FiniteMeetSemilattice._dual_class` is `FiniteJoinSemilattice`.

TESTS:

Equality is derived from `UniqueRepresentation`. We check that this gives consistent results:

```
sage: P = Poset([[1,2],[3],[3]])
sage: P == P
True
sage: Q = Poset([[1,2],[],[1]])
sage: Q == P
False
sage: p1, p2 = Posets(2).list()
sage: p2 == p1, p1 != p2
(False, True)
sage: [[p1.__eq__(p2) for p1 in Posets(2)] for p2 in Posets(2)]
[[True, False], [False, True]]
sage: [[p2.__eq__(p1) for p1 in Posets(2)] for p2 in Posets(2)]
[[True, False], [False, True]]
sage: [[p2 == p1 for p1 in Posets(3)] for p2 in Posets(3)]
[[True, False, False, False, False],
 [False, True, False, False, False],
 [False, False, True, False, False],
 [False, False, False, True, False],
 [False, False, False, False, True]]

sage: [[p1.__ne__(p2) for p1 in Posets(2)] for p2 in Posets(2)]
[[False, True], [True, False]]
sage: P = Poset([[1,2,4],[3],[3]])
sage: Q = Poset([[1,2],[],[1],[4]])
sage: P != Q
True
sage: P != P
False
sage: Q != Q
False
sage: [[p1.__ne__(p2) for p1 in Posets(2)] for p2 in Posets(2)]
[[False, True], [True, False]]

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: Q = Poset(P)
sage: Q == P
```

```
False
sage: Q = Poset(P, linear_extension=True)
sage: Q == P
True
```

Element
alias of PosetElement

antichains(*element_constructor=<type 'list'>*)
Return the antichains of the poset.

An *antichain* of a poset is a set of elements of the poset that are pairwise incomparable.

INPUT:

- element_constructor – a function taking an iterable as argument (default: list)

OUTPUT:

The enumerated set (of type PairwiseCompatibleSubsets) of all antichains of the poset, each of which is given as an element_constructor.

EXAMPLES:

```
sage: A = Posets.PentagonPoset().antichains(); A
Set of antichains of Finite lattice containing 5 elements
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
sage: A[3]
[1, 2]
```

To get the antichains as, say, sets, one may use the element_constructor option:

```
sage: list(Posets.ChainPoset(3).antichains(element_constructor=set))
[set(), {0}, {1}, {2}]
```

To get the antichains of a given size one can currently use:

```
sage: list(A.elements_of_depth_iterator(2))
[[1, 2], [1, 3]]
```

Eventually the following syntax will be accepted:

```
sage: A.subset(size = 2) # todo: not implemented
```

Note: Internally, this uses sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets and SearchForest. At this point, iterating through this set is about twice slower than using antichains_iterator() (tested on posets.AntichainPoset(15)). The algorithm is the same (depth first search through the tree), but antichains_iterator() manually inlines things which apparently avoids some infrastructure overhead.

On the other hand, this returns a full featured enumerated set, with containment testing, etc.

See also:

maximal_antichains(), chains()

antichains_iterator()
Return an iterator over the antichains of the poset.

EXAMPLES:

```
sage: it = Posets.PentagonPoset().antichains_iterator(); it
<generator object antichains_iterator at ...>
sage: it.next(), it.next()
([], [4])
```

See also:

antichains()

bottom()

Return the unique minimal element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

See also:

has_bottom(),top()

canonical_label()

Return the unique poset on the labels $\{0, \ldots, n-1\}$ (where n is the number of elements in the poset) that is isomorphic to this poset and invariant in the isomorphism class.

See also:

- Canonical labeling of directed graphs: canonical_label()

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True, facade=False)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.canonical_label()
sage: Q.list() # random
[0, 1, 2, 3, 4, 5]
sage: Q.is_isomorphic(P)
True
```

As a facade:

```
sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.canonical_label()
sage: sorted(Q.list())
[0, 1, 2, 3, 4, 5]
sage: Q.is_isomorphic(P)
True
```

Canonical labeling of (semi)lattice returns (semi)lattice:

```
sage: D=DiGraph({'a':['b','c']})
sage: P=Poset(D)
sage: ML=MeetSemilattice(D)
sage: P.canonical_label()
Finite poset containing 3 elements
sage: ML.canonical_label()
Finite meet-semilattice containing 3 elements
```

TESTS:

```
sage: P = Poset(digraphs.Path(10), linear_extension = True)
sage: Q = P.canonical_label()
sage: Q.linear_extension() # random
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: Q.cover_relations() # random
[[0, 1], [1, 2], [2, 3], [3, 4], [4, 5], [5, 6], [6, 7], [7, 8], [8, 9]]
sage: P = Poset(digraphs.Path(10))
sage: Q = P.canonical_label()
sage: Q.linear_extension() # random
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: Q.is_isomorphic(P)
True
```

cardinality()

Return the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).cardinality()
5
```

chain_polynomial()

Return the chain polynomial of `self`.

The coefficient of q^k is the number of chains of length k in `self`. The length of a chain is the number of elements.

Warning: This is not what has been called the chain polynomial in [St1986]. The latter is identical with the order polynomial (`order_polynomial()`).

EXAMPLES:

```
sage: P = Posets.ChainPoset(3)
sage: t = P.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
sage: t(1) == len(list(P.chains()))
True

sage: P = Posets.BooleanLattice(3)
sage: P.chain_polynomial()
6*q^4 + 18*q^3 + 19*q^2 + 8*q + 1

sage: P = Posets.AntichainPoset(5)
sage: P.chain_polynomial()
5*q + 1

sage: P = Poset({})
sage: P.chain_polynomial()
1
```

```
sage: parent(P.chain_polynomial())
Univariate Polynomial Ring in q over Integer Ring

sage: R = Poset({1: []})
sage: R.chain_polynomial()
q + 1
```

chain_polytope()

Return the chain polytope of the poset `self`.

The chain polytope of a finite poset P is defined as the subset of $\mathbf{R}^P$ consisting of all maps $x : P \to \mathbf{R}$ satisfying

$$x(p) \geq 0 \text{ for all } p \in P,$$

and

$$x(p_1) + x(p_2) + \ldots + x(p_k) \leq 1 \text{ for all chains } p_1 < p_2 < \ldots < p_k \text{ in } P.$$

This polytope was defined and studied in [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.chain_polytope();Q
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.chain_polytope();Q
A 5-dimensional polyhedron in QQ^5 defined as the convex hull of 8 vertices
```

chains(*element_constructor=<type 'list'>*, *exclude=None*)

Return the chains of the poset.

A *chain* of a poset is a set of elements of the poset that are pairwise comparable.

INPUT:

- `element_constructor` – a function taking an iterable as argument (default: `list`)
- `exclude` – elements of the poset to be excluded (default: `None`)

OUTPUT:

The enumerated set (of type `PairwiseCompatibleSubsets`) of all chains of the poset, each of which is given as an `element_constructor`.

EXAMPLES:

```
sage: C = Posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
sage: list(C)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4], [0, 3], [0, 3, 4],
```

Exclusion of vertices, tuple (instead of list) as constructor:

```
sage: P = Poset({1: [2, 3], 2: [4], 3: [4, 5]})
sage: list(P.chains(element_constructor=tuple, exclude=[3]))
[(), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,)]
```

To get the chains of a given size one can currently use:

```
sage: list(C.elements_of_depth_iterator(2))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]
```

Eventually the following syntax will be accepted:

```
sage: C.subset(size = 2) # todo: not implemented
```

See also:

maximal_chains(), antichains()

characteristic_polynomial()

Return the characteristic polynomial of the poset.

The poset is expected to be graded and have a bottom element.

If P is a graded poset with rank n and a unique minimal element $\hat{0}$, then the characteristic polynomial of P is defined to be

$$\sum_{x \in P} \mu(\hat{0}, x) q^{n-\rho(x)} \in \mathbf{Z}[q],$$

where ρ is the rank function, and μ is the Möbius function of P.

See section 3.10 of [EnumComb1].

EXAMPLES:

```
sage: P = Posets.DiamondPoset(5)
sage: P.characteristic_polynomial()
q^2 - 3*q + 2
sage: P = Poset({1:[2,3],2:[4],3:[5],4:[6],5:[6],6:[7]})
sage: P.characteristic_polynomial()
q^4 - 2*q^3 + q
sage: P = Poset({1: []})
sage: P.characteristic_polynomial()
1
```

closed_interval(*x*, *y*)

Return the list of elements z such that $x \leq z \leq y$ in the poset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.closed_interval(2, 100)
[2, 4, 10, 20, 50, 100]
```

See also:

open_interval()

TESTS:

```
sage: C = Posets.ChainPoset(10)
sage: C.closed_interval(3, 3)
[3]
sage: C.closed_interval(8, 5)
[]
sage: A = Posets.AntichainPoset(10)
sage: A.closed_interval(3, 7)
[]
```

comparability_graph()

Returns the comparability graph of `self`.

See Wikipedia article Comparability_graph

See also:

`incomparability_graph()`, `sage.graphs.comparability`

EXAMPLES:

```
sage: p = posets.ChainPoset(4)
sage: p.comparability_graph().is_isomorphic(graphs.CompleteGraph(4))
True

sage: p = posets.DiamondPoset(5)
sage: g = p.comparability_graph(); g
Comparability graph on 5 vertices
sage: g.size()
7
```

compare_elements(x, y)

Compare x and y in the poset.

- If $x < y$, return `-1`.
- If $x = y$, return `0`.
- If $x > y$, return `1`.
- If x and y are not comparable, return `None`.

EXAMPLES:

```
sage: P = Poset([[1, 2], [4], [3], [4], []])
sage: P.compare_elements(0, 0)
0
sage: P.compare_elements(0, 4)
-1
sage: P.compare_elements(4, 0)
1
sage: P.compare_elements(1, 2) is None
True
```

completion_by_cuts()

Return the completion by cuts of `self`.

This is a lattice, also called the Dedekind-MacNeille completion.

See the Wikipedia article Dedekind-MacNeille completion.

OUTPUT:

- a finite lattice

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.completion_by_cuts().is_isomorphic(P)
True

sage: P = posets.AntichainPoset(3)
sage: Q = P.completion_by_cuts()
sage: Q.is_isomorphic(posets.DiamondPoset(5))
True
```

```
sage: P = posets.SymmetricGroupBruhatOrderPoset(3)
sage: Q = P.completion_by_cuts(); Q
Finite lattice containing 7 elements
```

See also:

`cuts()`

connected_components()

Return the connected components of the poset as subposets.

EXAMPLES:

```
sage: P = Poset({1:[2,3], 3:[4,5]})
sage: CC = P.connected_components()
sage: CC[0] is P
True

sage: P = Poset({1:[2,3], 3:[4,5], 6:[7,8]})
sage: sorted(P.connected_components(), key=len)
[Finite poset containing 3 elements,
 Finite poset containing 5 elements]
```

TESTS:

```
sage: Poset().connected_components() # Test empty poset
[]
```

cover_relations()

Return the list of pairs `[x, y]` of elements of the poset such that `y` covers `x`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

cover_relations_graph()

Return the graph of cover relations.

EXAMPLES:

```
sage: P = Poset({0:[1,2],1:[3],2:[3],3:[]})
sage: G = P.cover_relations_graph(); G
Graph on 4 vertices
sage: S = Poset()
sage: H = S.cover_relations_graph(); H
Graph on 0 vertices
```

Check that it is hashable and coincides with the Hasse diagram as a graph:

```
sage: hash(G) == hash(G)
True
sage: G == Graph(P.hasse_diagram())
True
```

cover_relations_iterator()

Return an iterator over the cover relations of the poset.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: type(P.cover_relations_iterator())
<type 'generator'>
sage: [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

covers (*x*, *y*)

Return `True` if `y` covers `x` and `False` otherwise.

Element y covers x if $x < y$ and there is no z such that $x < z < y$.

EXAMPLES:

```
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.covers(1, 6)
True
sage: P.covers(1, 4)
False
sage: P.covers(1, 5)
False
```

coxeter_polynomial()

Return the Coxeter polynomial of the poset.

OUTPUT:

a polynomial in one variable

The output is the characteristic polynomial of the Coxeter transformation. This polynomial only depends on the derived category of modules on the poset.

See also:

`coxeter_transformation()`

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.coxeter_polynomial()
x^5 + x^4 + x + 1

sage: p = posets.SymmetricGroupWeakOrderPoset(3)
sage: p.coxeter_polynomial()
x^6 + x^5 - x^3 + x + 1
```

coxeter_transformation()

Return the Coxeter transformation of the poset.

OUTPUT:

a square matrix with integer coefficients

The output is the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules. This matrix is usually called the Coxeter transformation.

See also:

`coxeter_polynomial()`

EXAMPLES:

```
sage: Posets.PentagonPoset().coxeter_transformation()
[ 0  0  0  0 -1]
[ 0  0  0  1 -1]
[ 0  1  0  0 -1]
[-1  1  1  0 -1]
[-1  1  0  1 -1]
```

TESTS:

```
sage: M = posets.PentagonPoset().coxeter_transformation()
sage: M ** 8 == 1
True
```

cuts()

Return the list of cuts of the poset `self`.

A cut is a subset A of `self` such that the set of lower bounds of the set of upper bounds of A is exactly A.

The cuts are computed here using the maximal independent sets in the auxiliary graph defined as $P \times [0, 1]$ with an edge from $(x, 0)$ to $(y, 1)$ if and only if $x \not\geq_P y$. See the end of section 4 in [JRJ94].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Pc = P.cuts()
sage: [list(c) for c in Pc]
[[0], [0, 1, 2], [], [1], [2]]
sage: Pc[0]
frozenset({0})
```

See also:

`completion_by_cuts()`

REFERENCES:

deprecated_function_alias(*trac_number*, *func*)

Create an aliased version of a function or a method which raise a deprecation warning message.

If f is a function or a method, write `g = deprecated_function_alias(trac_number, f)` to make a deprecated aliased version of f.

INPUT:

- `trac_number` – integer. The trac ticket number where the deprecation is introduced.
- `func` – the function or method to be aliased

EXAMPLES:

```
sage: from sage.misc.superseded import deprecated_function_alias
sage: g = deprecated_function_alias(13109, number_of_partitions)
sage: g(5)
doctest:...: DeprecationWarning: g is deprecated. Please use sage.combinat.partition.number_
See http://trac.sagemath.org/13109 for details.
7
```

This also works for methods:

```
sage: class cls(object):
....:     def new_meth(self): return 42

dilworth_decomposition()

Return a partition of the points into the minimal number of chains.

According to Dilworth's theorem, the points of a poset can be partitioned into α chains, where α is the cardinality of its largest antichain. This method returns such a partition.

See Wikipedia article Dilworth's_theorem.

See also:

`width()` – return the width of the poset.

ALGORITHM:

We build a bipartite graph in which a vertex v of the poset is represented by two vertices v^-, v^+. For any two u, v such that $u < v$ in the poset we add an edge v^+u^-.

A matching in this graph is equivalent to a partition of the poset into chains: indeed, a chain $v_1...v_k$ gives rise to the matching $v_1^+v_2^-, v_2^+v_3^-$, ..., and from a matching one can build the union of chains.

According to Dilworth's theorem, the number of chains is equal to α (the posets' width).

EXAMPLES:

```
sage: p = posets.BooleanLattice(4)
sage: p.width()
6
sage: p.dilworth_decomposition()  # random
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

TESTS:

```
sage: p = posets.IntegerCompositions(5)
sage: d = p.dilworth_decomposition()
sage: for chain in d:
....:     for i in range(len(chain)-1):
....:         assert p.is_greater_than(chain[i],chain[i+1])
sage: set(p) == set().union(*d)
True
```

dimension(*certificate=False*)

Return the dimension of the Poset.

The (Dushnik-Miller) dimension of a poset is the minimal number of total orders so that the poset can be defined as "intersection" of all of them. Mathematically said, dimension of a poset defined on a set X

of points is the smallest integer n such that there exists $P_1, ..., P_n$ linear extensions of P satisfying the following property:

$$u \leq_P v \text{ if and only if } \forall i, u \leq_{P_i} v$$

For more information, see the Wikipedia article Order_dimension.

INPUT:

- `certificate` (boolean; default:`False`) – whether to return an integer (the dimension) or a certificate, i.e. a smallest set of linear extensions.

Note: The speed of this function greatly improves when more efficient MILP solvers (e.g. Gurobi, CPLEX) are installed. See `MixedIntegerLinearProgram` for more information.

ALGORITHM:

As explained [FT00], the dimension of a poset is equal to the (weak) chromatic number of a hypergraph. More precisely:

> Let $inc(P)$ be the set of (ordered) pairs of incomparable elements of P, i.e. all uv and vu such that $u \not\leq_P v$ and $v \not\leq_P u$. Any linear extension of P is a total order on X that can be seen as the union of relations from P along with some relations from $inc(P)$. Thus, the dimension of P is the smallest number of linear extensions of P which *cover* all points of $inc(P)$.
>
> Consequently, $dim(P)$ is equal to the chromatic number of the hypergraph $\mathcal{H}_{inc}$, where $\mathcal{H}_{inc}$ is the hypergraph defined on $inc(P)$ whose sets are all $S \subseteq inc(P)$ such that $P \cup S$ is not acyclic.

We solve this problem through a `Mixed Integer Linear Program`.

EXAMPLES:

We create a poset, compute a set of linear extensions and check that we get back the poset from them:

```
sage: P = Poset([[1,4], [3], [4,5,3], [6], [], [6], []])
sage: P.dimension()
3
sage: L = P.dimension(certificate=True)
sage: L # random -- architecture-dependent
[[0, 2, 4, 5, 1, 3, 6], [2, 5, 0, 1, 3, 4, 6], [0, 1, 2, 3, 5, 6, 4]]
sage: Poset( (L[0], lambda x, y: all(l.index(x) < l.index(y) for l in L)) ) == P
True
```

According to Schnyder's theorem, the poset (of height 2) of a graph has dimension ≤ 3 if and only if the graph is planar:

```
sage: G = graphs.CompleteGraph(4)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges()}))
sage: P.dimension()
3

sage: G = graphs.CompleteBipartiteGraph(3,3)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges()}))
sage: P.dimension() # not tested - around 4s with CPLEX
4
```

TESTS:

Empty Poset:

```
sage: Poset().dimension()
0
```

```
sage: Poset().dimension(certificate=True)
[]
```

REFERENCES:

disjoint_union(*other*, *labels='pairs'*)

Return a poset isomorphic to disjoint union (also called direct sum) of the poset with `other`.

The disjoint union of P and Q is a poset that contains every element and relation from both P and Q, and where every element of P is incomparable to every element of Q.

Mathematically, it is only defined when P and Q have no common element; here we force that by giving them different names in the resulting poset.

INPUT:

- `other`, a poset.
- `labels` - (defaults to 'pairs') If set to 'pairs', each element `v` in this poset will be named `(0,v)` and each element `u` in `other` will be named `(1,u)` in the result. If set to 'integers', the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

```
sage: P1 = Poset( (['a', 'b'], [['a', 'b']]) )
sage: P2 = Poset( (['c', 'd'], [['c', 'd']]) )
sage: P = P1.disjoint_union(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[(0, 'a'), (0, 'b')], [(1, 'c'), (1, 'd')]]
sage: P = P1.disjoint_union(P2, labels='integers');
sage: P.cover_relations()
[[2, 3], [0, 1]]

sage: N5 = Posets.PentagonPoset(); N5
Finite lattice containing 5 elements
sage: N5.disjoint_union(N5)  # Union of lattices is not a lattice
Finite poset containing 10 elements
```

We show how to get literally direct sum with elements untouched:

```
sage: P = P1.disjoint_union(P2).relabel(lambda x: x[1])
sage: sorted(P.cover_relations())
[['a', 'b'], ['c', 'd']]
```

dual()

Return the dual poset of the given poset.

EXAMPLES:

```
sage: P = Poset(([1,2,3],[[1,2],[1,3]]))
sage: P.cover_relations()
[[1, 2], [1, 3]]
sage: Q = P.dual()
sage: Q.cover_relations()
[[3, 1], [2, 1]]

sage: P = LatticePoset([[1,2],[3],[3]], facade = True)
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 3], [2, 3]]
sage: Q = P.dual()
sage: Q.cover_relations()
```

```
[[3, 2], [3, 1], [2, 0], [1, 0]]
sage: Q.category()
Join of Category of finite lattice posets
    and Category of finite enumerated sets
    and Category of facade sets
sage: Q.__class__
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>

sage: P = MeetSemilattice([[1,2],[3],[3]])
sage: P.dual().__class__
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
sage: P = JoinSemilattice([[1,2],[3],[3]])
sage: P.dual().__class__
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

evacuation()

Compute evacuation on the linear extension associated to the poset `self`.

OUTPUT:

- an isomorphic poset, with the same default linear extension

Evacuation is defined on a poset `self` of size n by applying the evacuation operator $(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$, to the default linear extension π of `self` (see `evacuation()`), and relabeling `self` accordingly. For more details see [Stan2009].

See also:

- `linear_extension()`
- `with_linear_extension()` and the `linear_extension` option of `Poset()`
- `evacuation()`
- `promotion()`

REFERENCES:

EXAMPLES:

```
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.evacuation()
Finite poset containing 2 elements with distinguished linear extension
sage: P.evacuation() == P
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]), linear_exter
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]
```

Note that the results depend on the linear extension associated to the poset:

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
```

```
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 3], [5, 6], [5, 4], [6, 7], [4, 7]]
```

Here is an example of a poset where the vertices are not labelled by $\{1, 2, \ldots, n\}$:

```
sage: P = Poset((divisors(15), attrcall("divides")), linear_extension = True)
sage: P.list()
[1, 3, 5, 15]
sage: Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]
```

AUTHOR:

- Anne Schilling (2012-02-18)

f_polynomial()

Return the f-polynomial of a bounded poset `self`.

This is the f-polynomial of the order complex of the poset minus its bounds.

The coefficient of q^i is the number of chains of $i+1$ elements containing both bounds of the poset.

See also:

`is_bounded()`, `h_polynomial()`, `order_complex()`, `sage.homology.cell_complex.GenericCellC`

Warning: This is slightly different from the `fPolynomial` method in Macaulay2.

EXAMPLES:

```
sage: P = Posets.DiamondPoset(5)
sage: P.f_polynomial()
3*q^2 + q
sage: P = Poset({1:[2,3],2:[4],3:[5],4:[6],5:[7],6:[7]})
sage: P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q

sage: P = Poset({2: []})
sage: P.f_polynomial()
1
```

flag_f_polynomial()

Return the flag f-polynomial of a bounded and ranked poset `self`.

This is the sum, over all chains containing both bounds, of a monomial encoding the ranks of the elements of the chain.

More precisely, if P is a bounded ranked poset, then the flag f-polynomial of P is defined as the polynomial

$$\sum_{\substack{p_0<p_1<\ldots<p_k, \\ p_0=\min P,\ p_k=\max P}} x_{\rho(p_1)} x_{\rho(p_2)} \cdots x_{\rho(p_k)} \in \mathbf{Z}[x_1, x_2, \cdots, x_n]$$

where $\min P$ and $\max P$ are (respectively) the minimum and the maximum of P, where ρ is the rank function of P (normalized to satisfy $\rho(\min P) = 0$), and where n is the rank of $\max P$. (Note that the indeterminate x_0 doesn't actually appear in the polynomial.)

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbf{Z}[x_0, x_1, x_2, \cdots, x_{n+1}]$ by this method.

See Wikipedia article h-vector.

See also:

`is_bounded()`, `flag_h_polynomial()`

EXAMPLES:

```
sage: P = Posets.DiamondPoset(5)
sage: P.flag_f_polynomial()
3*x1*x2 + x2

sage: P = Poset({1:[2,3],2:[4],3:[5],4:[6],5:[6]})
sage: fl = P.flag_f_polynomial(); fl
2*x1*x2*x3 + 2*x1*x3 + 2*x2*x3 + x3
sage: q = polygen(ZZ,'q')
sage: fl(q,q,q,q) == P.f_polynomial()
True

sage: P = Poset({1:[2,3,4],2:[5],3:[5],4:[5],5:[6]})
sage: P.flag_f_polynomial()
3*x1*x2*x3 + 3*x1*x3 + x2*x3 + x3

sage: P = Poset({2: [3]})
sage: P.flag_f_polynomial()
x1

sage: P = Poset({2: []})
sage: P.flag_f_polynomial()
1
```

flag_h_polynomial()

Return the flag h-polynomial of a bounded and ranked poset `self`.

If P is a bounded ranked poset whose maximal element has rank n (where the minimal element is set to have rank 0), then the flag h-polynomial of P is defined as the polynomial

$$\prod_{k=1}^{n}(1-x_k)\cdot f\left(\frac{x_1}{1-x_1},\frac{x_2}{1-x_2},\cdots,\frac{x_n}{1-x_n}\right)\in\mathbf{Z}[x_1,x_2,\cdots,x_n],$$

where f is the flag f-polynomial of P (see `flag_f_polynomial()`).

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbf{Q}[x_0,x_1,x_2,\cdots,x_{n+1}]$ by this method.

See Wikipedia article h-vector.

See also:

`is_bounded()`, `flag_f_polynomial()`

EXAMPLES:

```
sage: P = Posets.DiamondPoset(5)
sage: P.flag_h_polynomial()
2*x1*x2 + x2

sage: P = Poset({1:[2,3],2:[4],3:[5],4:[6],5:[6]})
sage: fl = P.flag_h_polynomial(); fl
-x1*x2*x3 + x1*x3 + x2*x3 + x3
sage: q = polygen(ZZ,'q')
sage: fl(q,q,q,q) == P.h_polynomial()
True
```

```
sage: P = Poset({1:[2,3,4],2:[5],3:[5],4:[5],5:[6]})
sage: P.flag_h_polynomial()
2*x1*x3 + x3

sage: P = posets.ChainPoset(4)
sage: P.flag_h_polynomial()
x3

sage: P = Poset({2: [3]})
sage: P.flag_h_polynomial()
x1

sage: P = Poset({2: []})
sage: P.flag_h_polynomial()
1
```

frank_network()

Computes Frank's network of the poset `self`.

This is defined in Section 8 of [BF1999].

OUTPUT:

A pair (G, e), where G is Frank's network of P encoded as a `DiGraph`, and e is the cost function on its edges encoded as a dictionary (indexed by these edges, which in turn are encoded as tuples of 2 vertices).

Note: Frank's network of P is a certain directed graph with $2|P| + 2$ vertices, defined in Section 8 of [BF1999]. Its set of vertices consists of two vertices $(0, p)$ and $(1, p)$ for each element p of P, as well as two vertices $(-1, 0)$ and $(2, 0)$. (These notations are not the ones used in [BF1999]; see the table below for their relation.) The edges are:

- for each p in P, an edge from $(-1, 0)$ to $(0, p)$;
- for each p in P, an edge from $(1, p)$ to $(2, 0)$;
- for each p and q in P such that $p \geq q$, an edge from $(0, p)$ to $(1, q)$.

We make this digraph into a network in the sense of flow theory as follows: The vertex $(-1, 0)$ is considered as the source of this network, and the vertex $(2, 0)$ as the sink. The cost function is defined to be 1 on the edge from $(0, p)$ to $(1, p)$ for each $p \in P$, and to be 0 on every other edge. The capacity is 1 on each edge. Here is how to translate this notations into that used in [BF1999]:

```
our notations                    [BF1999]
   (-1, 0)                         s
   (0, p)                        x_p
   (1, p)                        y_p
   (2, 0)                         t
    a[e]                        a(e)
```

```

AUTHOR:

- Darij Grinberg (2013-05-09)

ge (*x*, *y*)

Return `True` if x is greater than or equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

See also:

`is_greater_than()`, `is_lequal()`.

graphviz_string(*graph_string='graph'*, *edge_string='–'*)

Returns a representation in the DOT language, ready to render in graphviz.

REFERENCES:

- http://www.graphviz.org/doc/info/lang.html

EXAMPLES:

```
sage: P = Poset({'a':['b'],'b':['d'],'c':['d'],'d':['f'],'e':['f'],'f':[]})
sage: print P.graphviz_string()
graph {
"f";"d";"b";"a";"c";"e";
"f"--"e";"d"--"c";"b"--"a";"d"--"b";"f"--"d";
}
```

greene_shape()

Return the Greene-Kleitman partition of `self`.

The Greene-Kleitman partition of a finite poset P is the partition $(c_1 - c_0, c_2 - c_1, c_3 - c_2, \ldots)$, where c_k is the maximum cardinality of a union of k chains of P. Equivalently, this is the conjugate of the partition $(a_1 - a_0, a_2 - a_1, a_3 - a_2, \ldots)$, where a_k is the maximum cardinality of a union of k antichains of P.

See many sources, e. g., [BF1999], for proofs of this equivalence.

EXAMPLES:

```
sage: P = Poset([[3,2,1],[[3,1],[2,1]]])
sage: P.greene_shape()
[2, 1]
sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])
sage: P.greene_shape()
[3, 1]
sage: P = Poset([[1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22],[[1,4],[2,4],[4,
sage: P.greene_shape()
[3, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: P = Poset([[],[]])
sage: P.greene_shape()
[]
```

AUTHOR:

- Darij Grinberg (2013-05-09)

gt(*x*, *y*)

Return `True` if x is greater than but not equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
```

For non-facade posets also > works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

See also:

is_gequal(), is_less_than().

h_polynomial()

Return the h-polynomial of a bounded poset `self`.

This is the h-polynomial of the order complex of the poset minus its bounds.

This is related to the f-polynomial by a simple change of variables:

$$h(q) = (1-q)^{\deg f} f\left(\frac{q}{1-q}\right),$$

where f and h denote the f-polynomial and the h-polynomial, respectively.

See Wikipedia article h-vector.

See also:

is_bounded(), f_polynomial(), order_complex(), sage.homology.simplicial_complex.Simpli

Warning: This is slightly different from the `hPolynomial` method in Macaulay2.

EXAMPLES:

```
sage: P = Posets.AntichainPoset(3).order_ideals_lattice()
sage: P.h_polynomial()
q^3 + 4*q^2 + q
sage: P = Posets.DiamondPoset(5)
sage: P.h_polynomial()
2*q^2 + q
sage: P = Poset({1: []})
sage: P.h_polynomial()
1
```

has_bottom()

Return `True` if the poset has a unique minimal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1], 1:[]})
```

```
sage: Q.has_bottom()
True
```

See also:

bottom(), has_top(), is_bounded()

TESTS:

```
sage: Poset().has_top()  # Test empty poset
False
```

has_isomorphic_subposet(*other*)

Return True if the poset contains a subposet isomorphic to other.

By subposet we mean that there exist a set X of elements such that self.subposet(X) is isomorphic to other.

INPUT:

- other – a finite poset

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: T = Poset({1:[2,3], 2:[4,5], 3:[6,7]})
sage: N5 = Posets.PentagonPoset()

sage: N5.has_isomorphic_subposet(T)
False
sage: N5.has_isomorphic_subposet(D)
True

sage: len([P for P in Posets(5) if P.has_isomorphic_subposet(D)])
11
```

has_top()

Return True if the poset has a unique maximal element, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: Q.has_top()
True
```

See also:

top(), has_bottom(), is_bounded()

TESTS:

```
sage: Poset().has_top()  # Test empty poset
False
```

hasse_diagram(*wrapped=True*)

Return the Hasse diagram of self as a Sage DiGraph. If dot2tex is installed, then this sets the Hasse diagram's latex options to use the dot2tex formatting.

Todo

Should the vertices of the diagram have the poset as parent?

EXAMPLES:

```
sage: Q = Poset({5:[2,3], 1:[3,4], 2:[0], 3:[0], 4:[0]}, facade = False)
sage: Q.hasse_diagram()
Digraph on 6 vertices

sage: P = Poset({'a':['b'],'b':['d'],'c':['d'],'d':['f'],'e':['f'],'f':[]}, facade = False)
sage: H = P.hasse_diagram()
sage: P.cover_relations()
[[e, f], [c, d], [a, b], [b, d], [d, f]]
sage: H.edges()
[(a, b, None), (c, d, None), (b, d, None), (e, f, None), (d, f, None)]

sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: H = P.hasse_diagram()
sage: H.vertices()
[1, 3, 5, 15]
sage: H.edges()
[(1, 3, None), (1, 5, None), (3, 15, None), (5, 15, None)]
sage: H.set_latex_options(format="dot2tex")   # optional - dot2tex
sage: view(H, tight_page=True)  # optional - dot2tex, not tested (opens external window)
```

height()

Return the height (number of elements in a longest chain) of the poset.

EXAMPLES:

```
sage: P = Poset({0:[1],2:[3,4],4:[5,6]})
sage: P.height()
3
sage: Posets.PentagonPoset().height()
4
```

TESTS:

```
sage: Poset().height()
0
```

incidence_algebra(*R*, *prefix='I'*)

Return the incidence algebra of `self` over `R`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements
 over Rational Field
```

incomparability_graph()

Returns the incomparability graph of `self`.

This is the complement of the comparability graph.

See also:

`comparability_graph()`, `sage.graphs.comparability`

EXAMPLES:

```
sage: p = posets.ChainPoset(4)
sage: p.incomparability_graph().size()
0

sage: p = posets.DiamondPoset(5)
sage: g = p.incomparability_graph(); g
Incomparability graph on 5 vertices
sage: g.size()
3
```

interval(*x*, *y*)

Return a list of the elements z such that $x \leq z \leq y$.

INPUT:

- x – any element of the poset
- y – any element of the poset

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[2,5,6,4,7]))
sage: I == set(P.interval(2,7))
True

sage: dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
sage: P = Poset(dg, facade = False)
sage: P.interval("a","d")
[a, b, c, d]
```

intervals(**args*, ***kwds*)

Deprecated: Use `relations()` instead. See trac ticket #19360 for details.

intervals_iterator(**args*, ***kwds*)

Deprecated: Use `relations_iterator()` instead. See trac ticket #19360 for details.

intervals_number()

Return the number of relations in the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

See also:

`relations_iterator()`, `relations()`

EXAMPLES:

```
sage: P = Posets.PentagonPoset()
sage: P.relations_number()
13

sage: from sage.combinat.tamari_lattices import TamariLattice
sage: TamariLattice(4).relations_number()
68
```

TESTS:

```
sage: Poset().relations_number()
0
```

is_EL_labelling(*f*, *return_raising_chains=False*)

Returns `True` if `f` is an EL labelling of `self`.

A labelling f of the edges of the Hasse diagram of a poset is called an EL labelling (edge lexicographic labelling) if for any two elements u and v with $u \leq v$,

- there is a unique f-raising chain from u to v in the Hasse diagram, and this chain is lexicographically first among all chains from u to v.

For more details, see [Bj1980].

INPUT:

- `f` – a function taking two elements `a` and `b` in `self` such that `b` covers `a` and returning elements in a totally ordered set.
- `return_raising_chains` (optional; default:`False`) if `True`, returns the set of all raising chains in `self`, if possible.

EXAMPLES:

Let us consider a Boolean poset:

```
sage: P = Poset([[(0,0),(0,1),(1,0),(1,1)],[[(0,0),(0,1)],[(0,0),(1,0)],[(0,1),(1,1)],[(1,0)
sage: label = lambda a,b: min( i for i in [0,1] if a[i] != b[i] )
sage: P.is_EL_labelling(label)
True
sage: P.is_EL_labelling(label,return_raising_chains=True)
{((0, 0), (0, 1)): [1],
 ((0, 0), (1, 0)): [0],
 ((0, 0), (1, 1)): [0, 1],
 ((0, 1), (1, 1)): [0],
 ((1, 0), (1, 1)): [1]}
```

REFERENCES:

is_bounded()

Return `True` if the poset is bounded, and `False` otherwise.

A poset is bounded if it contains both a unique maximal element and a unique minimal element.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.is_bounded()
False
sage: Q = Posets.DiamondPoset(5)
sage: Q.is_bounded()
True
```

See also:

`has_bottom()`, `has_top()`

TESTS:

```
sage: Poset().is_bounded()  # Test empty poset
False
sage: Poset({1:[]}).is_bounded()  # Here top == bottom
True
```

```
sage: ( len([P for P in Posets(5) if P.is_bounded()]) ==
....: Posets(3).cardinality() )
True
```

is_chain()

Return `True` if the poset is totally ordered ("chain"), and `False` otherwise.

EXAMPLES:

```
sage: I = Poset({0:[1], 1:[2], 2:[3], 3:[4]})
sage: I.is_chain()
True

sage: II = Poset({0:[1], 2:[3]})
sage: II.is_chain()
False

sage: V = Poset({0:[1, 2]})
sage: V.is_chain()
False
```

TESTS:

```
sage: [len([P for P in Posets(n) if P.is_chain()]) for n in range(5)]
[1, 1, 1, 1, 1]
```

is_chain_of_poset(*elms*, *ordered=False*)

Return `True` if $elms$ is a chain of the poset, and `False` otherwise.

INPUT:

- `elms` – a list or other iterable containing some elements of the poset
- `ordered` – a Boolean. If `True`, then return `True` only if elements in $elms$ are strictly increasing in the poset; this makes no sense if $elms$ is a set. If `False` (the default), then elements can be repeated and be in any order.

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: sorted(P.list())
[1, 2, 3, 4, 6, 12]
sage: P.is_chain_of_poset([12, 3])
True
sage: P.is_chain_of_poset({3, 4, 12})
False
sage: P.is_chain_of_poset([12, 3], ordered=True)
False
sage: P.is_chain_of_poset((1, 1, 3))
True
sage: P.is_chain_of_poset((1, 1, 3), ordered=True)
False
sage: P.is_chain_of_poset((1, 3), ordered=True)
True
```

TESTS:

```
sage: P = Posets.BooleanLattice(4)
sage: P.is_chain_of_poset([])
True
sage: P.is_chain_of_poset((1,3,7,15,14))
```

```
False
sage: P.is_chain_of_poset({10})
True
sage: P.is_chain_of_poset([32])
Traceback (most recent call last):
...
ValueError: element (=32) not in poset
```

is_connected()

Return `True` if the poset is connected, and `False` otherwise.

A poset is connected if it's Hasse diagram is connected.

If a poset is not connected, then it can be divided to parts S_1 and S_2 so that every element of S_1 is incomparable to every element of S_2.

EXAMPLES:

```
sage: P = Poset({1:[2, 3], 3:[4, 5]})
sage: P.is_connected()
True

sage: P = Poset({1:[2, 3], 3:[4, 5], 6:[7, 8]})
sage: P.is_connected()
False
```

See also:

`connected_components()`

TESTS:

```
sage: Poset().is_connected()  # Test empty poset
True
```

is_eulerian()

Return `True` if the poset is Eulerian, and `False` otherwise.

The poset is expected to be graded and bounded.

A poset is Eulerian if every non-trivial interval has the same number of elements of even rank as of odd rank.

See Wikipedia article Eulerian_poset.

EXAMPLES:

```
sage: P = Poset({0:[1, 2, 3], 1:[4, 5], 2:[4, 6], 3:[5, 6],
....: 4:[7, 8], 5:[7, 8], 6:[7, 8], 7:[9], 8:[9]})
sage: P.is_eulerian()
True
sage: P = Poset({0:[1, 2, 3], 1:[4, 5, 6], 2:[4, 6], 3:[5,6],
....: 4:[7], 5:[7], 6:[7]})
sage: P.is_eulerian()
False
```

Canonical examples of Eulerian posets are the face lattices of convex polytopes:

```
sage: P = polytopes.cube().face_lattice()
sage: P.is_eulerian()
True
```

TESTS:

```
sage: Poset().is_eulerian()
Traceback (most recent call last):
...
TypeError: the poset is not bounded
sage: Posets.PentagonPoset().is_eulerian()
Traceback (most recent call last):
...
TypeError: the poset is not graded
sage: Poset({1: []}).is_eulerian()
True
```

is_gequal(*x*, *y*)

Return `True` if x is greater than or equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

See also:

`is_greater_than()`, `is_lequal()`.

is_graded()

Return `True` if the poset is graded, and `False` otherwise.

A poset is graded if all its maximal chains have the same length.

There are various competing definitions for graded posets (see Wikipedia article Graded_poset). This definition is from section 3.1 of Richard Stanley's *Enumerative Combinatorics, Vol. 1* [EnumComb1].

Every graded poset is ranked. The converse is true for bounded posets, including lattices.

EXAMPLES:

```
sage: P = Posets.PentagonPoset()  # Not even ranked
sage: P.is_graded()
False

sage: P = Poset({1:[2, 3], 3:[4]})  # Ranked, but not graded
sage: P.is_graded()
False

sage: P = Poset({1:[3, 4], 2:[3, 4], 5:[6]})
sage: P.is_graded()
True

sage: P = Poset([[1], [2], [], [4], []])
sage: P.is_graded()
False
```

See also:

`is_ranked()`, `level_sets()`

TESTS:

```
sage: Poset().is_graded()  # Test empty poset
True
```

is_greater_than(*x*, *y*)

Return `True` if x is greater than but not equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
```

For non-facade posets also > works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

See also:

`is_gequal()`, `is_less_than()`.

is_incomparable_chain_free(*m*, *n=None*)

Return `True` if the poset is $(m+n)$-free, and `False` otherwise.

A poset is $(m+n)$-free if there is no incomparable chains of lengths m and n. Three cases have special name:

- ''interval order'' is $(2+2)$-free
- ''semiorder'' (or ''unit interval order'') is $(1+3)$-free and $(2+2)$-free
- ''weak order'' is $(1+2)$-free.

INPUT:

- `m`, `n` - positive integers

It is also possible to give a list of integer pairs as argument. See below for an example.

EXAMPLES:

```
sage: B3 = Posets.BooleanLattice(3)
sage: B3.is_incomparable_chain_free(1, 3)
True
sage: B3.is_incomparable_chain_free(2, 2)
False

sage: IP6 = Posets.IntegerPartitions(6)
sage: IP6.is_incomparable_chain_free(1, 3)
False
sage: IP6.is_incomparable_chain_free(2, 2)
True
```

A list of pairs as an argument:

```
sage: B3.is_incomparable_chain_free([[1, 3], [2, 2]])
False
```

We show how to get an incomparable chain pair:

```
sage: P = Posets.PentagonPoset()
sage: chains_1_2 = Poset({0:[], 1:[2]})
sage: incomps = P.isomorphic_subposets(chains_1_2)[0]
sage: sorted(incomps.list()), incomps.cover_relations()
([1, 2, 3], [[2, 3]])
```

TESTS:

```
sage: Poset().is_incomparable_chain_free(1,1)  # Test empty poset
True

sage: [len([p for p in Posets(n) if p.is_incomparable_chain_free(((3, 1), (2, 2)))]) for n i
[1, 1, 2, 5, 14, 42]

sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: Q.is_incomparable_chain_free(2, 20/10)
True
sage: Q.is_incomparable_chain_free(2, pi)
Traceback (most recent call last):
...
TypeError: 2 and pi must be integers.
sage: Q.is_incomparable_chain_free(2, -1)
Traceback (most recent call last):
...
ValueError: 2 and -1 must be positive integers.
sage: P = Poset(((0, 1, 2, 3, 4), ((0, 1), (1, 2), (0, 3), (4, 2))))
sage: P.is_incomparable_chain_free((3, 1))
Traceback (most recent call last):
...
TypeError: (3, 1) is not a tuple of tuples.
sage: P.is_incomparable_chain_free([3, 1], [2, 2])
Traceback (most recent call last):
...
TypeError: [3, 1] and [2, 2] must be integers.
sage: P.is_incomparable_chain_free([[3, 1], [2, 2]])
True
sage: P.is_incomparable_chain_free(([3, 1], [2, 2]))
True
sage: P.is_incomparable_chain_free([3, 1], 2)
Traceback (most recent call last):
...
TypeError: [3, 1] and 2 must be integers.
sage: P.is_incomparable_chain_free(([3, 1], [2, 2, 2]))
Traceback (most recent call last):
...
ValueError: '([3, 1], [2, 2, 2])' is not a tuple of length-2 tuples.
```

AUTHOR:

- Eric Rowland (2013-05-28)

REFERENCES:

is_induced_subposet(*other*)

Return `True` if the poset is an induced subposet of `other`, and `False` otherwise.

A poset P is an induced subposet of Q if every element of P is an element of Q, and $x \leq_P y$ iff $x \leq_Q y$. Note that "induced" here has somewhat different meaning compared to that of graphs.

INPUT:

- `other`, a poset.

Note: This method does not check whether the poset is a *isomorphic* (i.e., up to relabeling) subposet of `other`, but only if `other` directly contains the poset as an induced subposet. For isomorphic subposets see `has_isomorphic_subposet()`.

EXAMPLES:

```
sage: P = Poset({1:[2, 3]})
sage: Q = Poset({1:[2, 4], 2:[3]})
sage: P.is_induced_subposet(Q)
False
sage: R = Poset({0:[1], 1:[3, 4], 3:[5], 4:[2]})
sage: P.is_induced_subposet(R)
True
```

TESTS:

```
sage: P = Poset({2:[1]})
sage: Poset().is_induced_subposet(P)
True
sage: Poset().is_induced_subposet(Poset())
True
sage: P.is_induced_subposet(Poset())
False
```

Bad input:

```
sage: Poset().is_induced_subposet('junk')
Traceback (most recent call last):
...
AttributeError: 'str' object has no attribute 'subposet'
```

is_isomorphic(*other*)

Returns True if both posets are isomorphic.

EXAMPLES:

```
sage: P = Poset(([1,2,3],[[1,3],[2,3]]))
sage: Q = Poset(([4,5,6],[[4,6],[5,6]]))
sage: P.is_isomorphic( Q )
True
```

is_join_semilattice()

Return `True` if the poset has a join operation, and `False` otherwise.

A join is the least upper bound for given elements, if it exists.

EXAMPLES:

```
sage: P = Poset([[1,3,2], [4], [4,5,6], [6], [7], [7], [7], []])
sage: P.is_join_semilattice()
True
```

Elements 3 and 4 have no common upper bound at all; elements 1 and 2 have upper bounds 3 and 4, but no least upper bound:

```
sage: P = Poset({1:[3, 4], 2:[3, 4]})
sage: P.is_join_semilattice()
False
```

See also:

is_meet_semilattice(), is_lattice()

TESTS:

```
sage: Poset().is_join_semilattice()  # Test empty lattice
True
sage: len([P for P in Posets(4) if P.is_join_semilattice()])
5
```

is_lequal(x, y)

Return `True` if x is less than or equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False
```

See also:

is_less_than(), is_gequal().

is_less_than(x, y)

Return `True` if x is less than but not equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
sage: P.is_less_than(2, 2)
False
```

For non-facade posets also < works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(1) < P(2)
False
```

See also:

is_lequal(), is_greater_than().

is_linear_extension(l)

Returns whether `l` is a linear extension of `self`

INPUT:

- `l` – a list (or iterable) containing all of the elements of `self` exactly once

See also:

linear_extension(), linear_extensions()

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.is_linear_extension([1, 2, 4, 3, 6, 12])
True
sage: P.is_linear_extension([1, 2, 4, 6, 3, 12])
False

sage: [p for p in Permutations(list(P)) if P.is_linear_extension(p)]
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
sage: list(P.linear_extensions())
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
```

Note: This is used and systematically tested in LinearExtensionsOfPosets

TESTS:

Check that trac ticket #15313 is fixed:

```
sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_extension=True)
sage: P.is_linear_extension([1,2,4,3,6,12,1337])
False
sage: P.is_linear_extension([1,2,4,3,6,666,12,1337])
False
sage: P = Poset(DiGraph(5))
sage: P.is_linear_extension(['David', 'McNeil', 'La', 'Lamentable', 'Aventure', 'de', 'Simor
False
```

is_meet_semilattice()

Return True if the poset has a meet operation, and False otherwise.

A meet is the greatest lower bound for given elements, if it exists.

EXAMPLES:

```
sage: P = Poset({1:[2, 3, 4], 2:[5, 6], 3:[6], 4:[6, 7]})
sage: P.is_meet_semilattice()
True

sage: Q = P.dual()
sage: Q.is_meet_semilattice()
False
```

See also:

is_join_semilattice(), is_lattice()

TESTS:

```
sage: Poset().is_meet_semilattice()  # Test empty lattice
True
sage: len([P for P in Posets(4) if P.is_meet_semilattice()])
5
```

is_parent_of(*x*)

Returns True if x is an element of the poset.

TESTS:

```
sage: from sage.combinat.posets.posets import FinitePoset
sage: P5 = FinitePoset(DiGraph({(5,):[(4,1),(3,2)], \
        (4,1):[(3,1,1),(2,2,1)], \
        (3,2):[(3,1,1),(2,2,1)], \
        (3,1,1):[(2,1,1,1)], \
        (2,2,1):[(2,1,1,1)], \
        (2,1,1,1):[(1,1,1,1,1)], \
        (1,1,1,1,1):[]}))
sage: x = P5.list()[3]
sage: x in P5
True
```

For the sake of speed, an element with the right class and parent is assumed to be in this parent. This can possibly be counterfeited by feeding garbage to the constructor:

```
sage: x = P5.element_class(P5, "a", 5)
sage: x in P5
True
```

is_rank_symmetric()

Return `True` if the poset is rank symmetric, and `False` otherwise.

The poset is expected to be graded and connected.

A poset of rank h (maximal chains have $h+1$ elements) is rank symmetric if the number of elements are equal in ranks i and $h-i$ for every i in $0, 1, \ldots, h$.

EXAMPLES:

```
sage: P = Poset({1:[3, 4, 5], 2:[3, 4, 5], 3:[6], 4:[7], 5:[7]})
sage: P.is_rank_symmetric()
True
sage: P = Poset({1:[2], 2:[3, 4], 3:[5], 4:[5]})
sage: P.is_rank_symmetric()
False
```

TESTS:

```
sage: Poset().is_rank_symmetric()  # Test empty poset
True
```

is_ranked()

Return `True` if the poset is ranked, and `False` otherwise.

A poset is ranked if there is a function r from poset elements to integers so that $r(x) = r(y) + 1$ when x covers y.

Informally said a ranked poset can be "levelized": every element is on a "level", and every cover relation goes only one level up.

EXAMPLES:

```
sage: P = Poset( ([1, 2, 3, 4], [[1, 2], [2, 4], [3, 4]] ))
sage: P.is_ranked()
True

sage: P = Poset([[1, 5], [2, 6], [3], [4],[], [6, 3], [4]])
sage: P.is_ranked()
False
```

See also:

`rank_function()`, `rank()`, `is_graded()`

TESTS:

```
sage: Poset().is_ranked()  # Test empty poset
True
```

is_slender()

Return `True` if the poset is slender, and `False` otherwise.

A finite graded poset is called slender if every rank 2 interval contains three or four elements, as defined in [Stan2009]. (This notion of "slender" is unrelated to the eponymous notion defined by Graetzer and Kelly in "The Free $\mathfrak{m}$-Lattice on the Poset H", Order 1 (1984), 47–65.)

This function *does not* check if the poset is graded or not. Instead it just returns `True` if the poset does not contain 5 distinct elements x, y, a, b and c such that $x \lessdot a, b, c \lessdot y$ where $\lessdot$ is the covering relation.

EXAMPLES:

```
sage: P = Poset(([1, 2, 3, 4], [[1, 2], [1, 3], [2, 4], [3, 4]]))
sage: P.is_slender()
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[1,3],[1,4],[2,5],[3,5],[4,5]]))
sage: P.is_slender()
False

sage: W = WeylGroup(['A', 2])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: W = WeylGroup(['A', 3])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
```

TESTS:

```
sage: Poset().is_slender()  # Test empty poset
True
```

isomorphic_subposets(*other*)

Return a list of subposets of $self$ isomorphic to $other$.

By subposet we mean `self.subposet(X)` which is isomorphic to `other` and where `X` is a subset of elements of `self`.

INPUT:

- `other` – a finite poset

EXAMPLES:

```
sage: C2=Poset({0:[1]})
sage: C3=Poset({'a':['b'], 'b':['c']})
sage: for x in C3.isomorphic_subposets(C2): print x.cover_relations()
[['b', 'c']]
[['a', 'c']]
[['a', 'b']]
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: N5 = Posets.PentagonPoset()
sage: len(N5.isomorphic_subposets(D))
2
```

Note: If this function takes too much time, try using `isomorphic_subposets_iterator()`.

isomorphic_subposets_iterator(*other*)

Return an iterator over the subposets of $self$ isomorphic to $other$.

By subposet we mean `self.subposet(X)` which is isomorphic to `other` and where `X` is a subset of elements of `self`.

INPUT:

- `other` – a finite poset

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: N5 = Posets.PentagonPoset()
sage: for P in N5.isomorphic_subposets_iterator(D):
....:     print P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
```

Warning: This function will return same subposet as many times as there are automorphism on it. This is due to `subgraph_search_iterator()` returning labelled subgraphs. On the other hand, this function does not eat memory like `isomorphic_subposets()` does.

join_matrix()

Deprecated as a function of posets, moved to lattices.

Convert a poset P to join-semilattice and use it like `JoinSemilattice(P).join_matrix()`.

kazhdan_lusztig_polynomial(*x=None*, *y=None*, *q=None*, *canonical_labels=None*)

Return the Kazhdan-Lusztig polynomial $P_{x,y}(q)$ of `self`.

We follow the definition given in [EPW14]. Let G denote a graded poset with unique minimal and maximal elements and χ_G denote the characteristic polynomial of G. Let I_x and F^x denote the principal order ideal and filter of x respectively. Define the *Kazhdan-Lusztig polynomial* of G as the unique polynomial $P_G(q)$ satisfying the following:

1. If $\operatorname{rank} G = 0$, then $P_G(q) = 1$.
2. If $\operatorname{rank} G > 0$, then $\deg P_G(q) < \frac{1}{2} \operatorname{rank} G$.
3. We have

$$q^{\operatorname{rank} G} P_G(q^{-1}) = \sum_{x \in G} \chi_{I_x}(q) P_{F^x}(q).$$

We then extend this to $P_{x,y}(q)$ by considering the subposet corresponding to the (closed) interval $[x, y]$. We also define $P_{\emptyset}(q) = 0$ (so if $x \not\leq y$, then $P_{x,y}(q) = 0$).

INPUT:

- `q` – (default: $q \in \mathbf{Z}[q]$) the indeterminate q
- `x` – (default: the minimal element) the element x
- `y` – (default: the maximal element) the element y
- `canonical_labels` – (optional) for subposets, use the canonical labeling (this can limit recursive calls for posets with large amounts of symmetry, but producing the labeling takes time); if not specified, this is `True` if `x` and `y` are both not specified and `False` otherwise

EXAMPLES:

```
sage: L = posets.BooleanLattice(3)
sage: L.kazhdan_lusztig_polynomial()
1

sage: L = posets.SymmetricGroupWeakOrderPoset(4)
sage: L.kazhdan_lusztig_polynomial()
1
sage: x = '2314'
sage: y = '3421'
sage: L.kazhdan_lusztig_polynomial(x, y)
-q + 1
sage: L.kazhdan_lusztig_polynomial(x, y, var('t'))
-t + 1
```

REFERENCES:

AUTHORS:

- Travis Scrimshaw (27-12-2014)

le(*x*, *y*)

Return `True` if x is less than or equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False
```

See also:

`is_less_than()`, `is_gequal()`.

lequal_matrix(*ring=Integer Ring*, *sparse=False*)

Computes the matrix whose `(i,j)` entry is 1 if `self.linear_extension()[i] < self.linear_extension()[j]` and 0 otherwise.

INPUT:

- `ring` – the ring of coefficients (default: `ZZ`)
- `sparse` – whether the returned matrix is sparse or not (default: `True`)

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: LEQM = P.lequal_matrix(); LEQM
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 1 0 1 1]
[0 0 0 1 0 0 0 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
sage: LEQM[1,3]
1
sage: P.linear_extension()[1] < P.linear_extension()[3]
True
sage: LEQM[2,5]
0
sage: P.linear_extension()[2] < P.linear_extension()[5]
False
```

We now demonstrate the usage of the optional parameters:

```
sage: P.lequal_matrix(ring=QQ, sparse=False).parent()
Full MatrixSpace of 8 by 8 dense matrices over Rational Field
```

level_sets()

Return a list `l` such that `l[i]` is the set of minimal elements of the poset obtained from `self` by removing the elements in `l[0], l[1], ..., l[i-1]`. (In particular, `l[0]` is the set of minimal elements of `self`.)

EXAMPLES:

```
sage: P = Poset({0:[1,2],1:[3],2:[3],3:[]})
sage: [len(x) for x in P.level_sets()]
[1, 2, 1]

sage: Q = Poset({0:[1,2], 1:[3], 2:[4], 3:[4]})
sage: [len(x) for x in Q.level_sets()]
[1, 2, 1, 1]
```

linear_extension(*linear_extension=None*, *check=True*)

Return a linear extension of this poset.

A linear extension of a finite poset P of size n is a total ordering $\pi := \pi_0\pi_1\ldots\pi_{n-1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset P.

INPUT:

- `linear_extension` – (default: `None`) a list of the elements of `self`
- `check` – a boolean (default: True); whether to check that `linear_extension` is indeed a linear extension of `self`.

See also:

`is_linear_extension()`, `linear_extensions()`

EXAMPLES:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
```

Without optional argument, the default linear extension of the poset is returned, as a plain list:

```
sage: P.linear_extension()
[1, 3, 5, 15]
```

Otherwise, a full-featured linear extension is constructed as an element of `P.linear_extensions()`:

```
sage: l = P.linear_extension([1,5,3,15]); l
[1, 5, 3, 15]
sage: type(l)
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category.element
sage: l.parent()
The set of all linear extensions of Finite poset containing 4 elements
```

By default, the linear extension is checked for correctness:

```
sage: l = P.linear_extension([1,3,15,5])
Traceback (most recent call last):
...
ValueError: [1, 3, 15, 5] is not a linear extension of Finite poset containing 4 elements
```

This can be disabled (at your own risks!) with:

```
sage: P.linear_extension([1,3,15,5], check=False)
[1, 3, 15, 5]
```

Todo

- Is it acceptable to have those two features for a single method?
- In particular, we miss a short idiom to get the default linear extension

---

`linear_extensions` (*facade=False*)

Returns the enumerated set of all the linear extensions of this poset

INPUT:

- `facade` – a boolean (default: `False`); whether to return the linear extensions as plain lists

> **Warning:** The `facade` option is not yet fully functional:
>
> ```
> sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
> sage: L = P.linear_extensions(facade=True); L
> The set of all linear extensions of Finite poset containing 6 elements with distinguish
> sage: L([1, 2, 3, 4, 6, 12])
> Traceback (most recent call last):
> ...
> TypeError: Cannot convert list to sage.structure.element.Element
> ```

See also:

`linear_extension()`, `is_linear_extension()`

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: L = P.linear_extensions(); L
The set of all linear extensions of Finite poset containing 6 elements with distinguished li
```

```
sage: l = L.an_element(); l
[1, 2, 3, 4, 6, 12]
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
```

Each element is aware that it is a linear extension of P:

```
sage: type(l.parent())
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category'>
```

With `facade=True`, the elements of `L` are plain lists instead:

```
sage: L = P.linear_extensions(facade=True)
sage: l = L.an_element()
sage: type(l)
<type 'list'>
```

Warning: In Sage <= 4.8, this function used to return a plain list of lists. To recover the previous functionality, please use:

```
sage: L = list(P.linear_extensions(facade=True)); L
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
sage: type(L[0])
<type 'list'>
```

TESTS:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: list(D.linear_extensions())
[[0, 1, 2, 3, 4], [0, 1, 2, 4, 3], [0, 2, 1, 3, 4], [0, 2, 1, 4, 3], [0, 2, 4, 1, 3]]
```

linear_extensions_graph()

Return the linear extensions graph of the poset.

Vertices of the graph are linear extensions of the poset. Two vertices are connected by an edge if the linear extensions differ by only one adjacent transposition.

EXAMPLES:

```
sage: P = Poset({1:[3,4],2:[4]})
sage: G = P.linear_extensions_graph(); G
Graph on 5 vertices
sage: G.degree_sequence()
[3, 2, 2, 2, 1]

sage: chevron = Poset({1:[2,6], 2:[3], 4:[3,5], 6:[5]})
sage: G = chevron.linear_extensions_graph(); G
Graph on 22 vertices
```

```
sage: G.size()
36
```

TESTS:

```
sage: Poset().linear_extensions_graph()
Graph on 1 vertex

sage: A4 = Posets.AntichainPoset(4)
sage: G = A4.linear_extensions_graph()
sage: G.is_regular()
True
```

list()

List the elements of the poset. This just returns the result of `linear_extension()`.

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] }, facade = False)
sage: D.list()
[0, 1, 2, 3, 4]
sage: type(D.list()[0])
<class 'sage.combinat.posets.elements.FinitePoset_with_category.element_class'>
```

lower_covers(x)

Return the list of lower covers of the element `x`.

A lower cover of x is an element y such that $y < x$ and there is no element z so that $y < z < x$.

EXAMPLES:

```
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.lower_covers(3)
[2, 5]
sage: P.lower_covers(0)
[]
```

See also:

`upper_covers()`

lower_covers_iterator(x)

Return an iterator over the lower covers of the element `x`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
sage: l0 = P.lower_covers_iterator(3)
sage: type(l0)
<type 'generator'>
sage: l0.next()
2
```

lt(x, y)

Return `True` if x is less than but not equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
```

```
False
sage: P.is_less_than(2, 2)
False
```

For non-facade posets also < works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(1) < P(2)
False
```

See also:

is_lequal(), is_greater_than().

maximal_antichains()

Return the maximal antichains of the poset.

An antichain a of poset P is *maximal* if there is no element $e \in P \setminus a$ such that $a \cup \{e\}$ is an antichain.

EXAMPLES:

```
sage: P=Poset({'a':['b', 'c'], 'b':['d','e']})
sage: P.maximal_antichains()
[['a'], ['b', 'c'], ['c', 'd', 'e']]

sage: Posets.PentagonPoset().maximal_antichains()
[[0], [1, 2], [1, 3], [4]]
```

See also:

antichains(), maximal_chains()

maximal_chains(*partial=None*)

Return all maximal chains of this poset.

Each chain is listed in increasing order.

INPUT:

- partial – list (optional); if present, find all maximal chains starting with the elements in partial

Returns list of the maximal chains of this poset.

This is used in constructing the order complex for the poset.

EXAMPLES:

```
sage: P = Posets.BooleanLattice(3)
sage: P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7], [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7]]
sage: P.maximal_chains(partial=[0,2])
[[0, 2, 3, 7], [0, 2, 6, 7]]
sage: Q = Posets.ChainPoset(6)
sage: Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

See also:

maximal_antichains(), chains()

maximal_elements()

Return the list of the maximal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

See also:

minimal_elements().

meet_matrix()
Deprecated as a function of posets, moved to lattices.

Convert a poset P to meet-semilattice and use it like MeetSemilattice(P).join_matrix().

minimal_elements()
Return the list of the minimal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

See also:

maximal_elements().

mobius_function(**args*, ***kwds*)
Deprecated: Use moebius_function() instead. See trac ticket #19855 for details.

mobius_function_matrix(**args*, ***kwds*)
Deprecated: Use moebius_function_matrix() instead. See trac ticket #19855 for details.

moebius_function(*x*, *y*)
Returns the value of the Möbius function of the poset on the elements x and y.

EXAMPLES:

```
sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: P.moebius_function(P(0),P(4))
2
sage: sum([P.moebius_function(P(0),v) for v in P])
0
sage: sum([abs(P.moebius_function(P(0),v)) \
....:       for v in P])
6
sage: for u,v in P.cover_relations_iterator():
....:     if P.moebius_function(u,v) != -1:
....:         print "Bug in moebius_function!"

sage: Q = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: Q.moebius_function(Q(0),Q(7))
0
sage: Q.moebius_function(Q(0),Q(5))
0
sage: Q.moebius_function(Q(2),Q(7))
2
sage: Q.moebius_function(Q(3),Q(3))
1
```

```
sage: sum([Q.moebius_function(Q(0),v) for v in Q])
0
```

moebius_function_matrix(*ring=Integer Ring*, *sparse=False*)

Returns a matrix whose `(i,j)` entry is the value of the Möbius function evaluated at `self.linear_extension()[i]` and `self.linear_extension()[j]`.

INPUT:

- `ring` – the ring of coefficients (default: `ZZ`)
- `sparse` – whether the returned matrix is sparse or not (default: `True`)

EXAMPLES:

```
sage: P = Poset([[4,2,3],[],[1],[1],[1]])
sage: x,y = (P.linear_extension()[0],P.linear_extension()[1])
sage: P.moebius_function(x,y)
-1
sage: M = P.moebius_function_matrix(); M
[ 1 -1 -1 -1  2]
[ 0  1  0  0 -1]
[ 0  0  1  0 -1]
[ 0  0  0  1 -1]
[ 0  0  0  0  1]
sage: M[0,4]
2
sage: M[0,1]
-1
```

We now demonstrate the usage of the optional parameters:

```
sage: P.moebius_function_matrix(ring=QQ, sparse=False).parent()
Full MatrixSpace of 5 by 5 dense matrices over Rational Field
```

open_interval(*x*, *y*)

Return the list of elements z such that $x < z < y$ in the poset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.open_interval(2, 100)
[4, 10, 20, 50]
```

See also:

`closed_interval()`

TESTS:

```
sage: C = Posets.ChainPoset(10)
sage: C.open_interval(3, 3)
[]
sage: C.open_interval(3, 4)
[]
sage: C.open_interval(7, 3)
[]
sage: A = Posets.AntichainPoset(10)
sage: A.open_interval(3, 7)
[]
```

order_complex(*on_ints=False*)

Return the order complex associated to this poset.

The order complex is the simplicial complex with vertices equal to the elements of the poset, and faces given by the chains.

INPUT:

- `on_ints` – a boolean (default: False)

EXAMPLES:

```
sage: P = Posets.BooleanLattice(3)
sage: S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets
sage: S.f_vector()
[1, 8, 19, 18, 6]
sage: S.homology()      # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}
sage: Q = P.subposet([1,2,3,4,5,6])
sage: Q.order_complex().homology()    # a circle
{0: 0, 1: Z}

sage: P = Poset((divisors(15), attrcall("divides")), facade = True)
sage: P.order_complex()
Simplicial complex with vertex set (1, 3, 5, 15) and facets {(1, 3, 15), (1, 5, 15)}
```

If `on_ints`, then the elements of the poset are labelled $0, 1, \ldots$ in the chain complex:

```
sage: P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3), (0, 1, 3)}
```

order_filter(*elements*)

Return the order filter generated by the elements of an iterable `elements`.

I is an order filter if, for any x in I and y such that $y \geq x$, then y is in I. This is also called upper set or upset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_filter([20, 25])
[20, 40, 25, 50, 100, 200, 125, 250, 500, 1000]
```

See also:

`order_ideal()`, `principal_order_filter()`.

TESTS:

```
sage: P = Poset()  # Test empty poset
sage: P.order_filter([])
[]
sage: C = Posets.ChainPoset(5)
sage: C.order_filter([])
[]
```

order_ideal(*elements*)

Return the order ideal generated by the elements of an iterable `elements`.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I. This is also called lower set or downset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal([20, 25])
[1, 2, 4, 5, 10, 20, 25]
```

See also:

order_filter(),principal_order_ideal().

TESTS:

```
sage: P = Poset()  # Test empty poset
sage: P.order_ideal([])
[]
sage: C = Posets.ChainPoset(5)
sage: C.order_ideal([])
[]
```

order_polynomial()

Return the order polynomial of self.

The order polynomial $\Omega_P(q)$ of a poset P is defined as the unique polynomial S such that for each integer $m \geq 1$, $S(m)$ is the number of order-preserving maps from P to $\{1, \ldots, m\}$.

See sections 3.12 and 3.15 of [EnumComb1], and also [St1986].

See also:

order_polytope()

EXAMPLES:

```
sage: P = Posets.AntichainPoset(3)
sage: P.order_polynomial()
q^3

sage: P = Posets.ChainPoset(3)
sage: f = P.order_polynomial(); f
1/6*q^3 + 1/2*q^2 + 1/3*q
sage: [f(i) for i in range(4)]
[0, 1, 4, 10]
```

order_polytope()

Return the order polytope of the poset self.

The order polytope of a finite poset P is defined as the subset of $\mathbf{R}^P$ consisting of all maps $x : P \to \mathbf{R}$ satisfying

$$0 \leq x(p) \leq 1 \text{ for all } p \in P,$$

and

$$x(p) \leq x(q) \text{ for all } p, q \in P \text{ satisfying } p < q.$$

This polytope was defined and studied in [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.order_polytope();Q
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.order_polytope();Q
```

```
A 5-dimensional polyhedron in QQ^5 defined as the convex hull of 8 vertices

sage: P = Poset([[1,2,3],[[1,2],[1,3]]])
sage: Q = P.order_polytope()
sage: Q.contains((1,0,0))
False
sage: Q.contains((0,1,1))
True
```

REFERENCES:

ordinal_product(*other*, *labels='pairs'*)

Return the ordinal product of `self` and `other`.

The ordinal product of two posets P and Q is a partial order on the Cartesian product of the underlying sets of P and Q, defined as follows (see [EnumComb1], p. 284).

In the ordinal product, $(p, q) \leq (p', q')$ if either $p \leq p'$ or $p = p'$ and $q \leq q'$.

This construction is not symmetric in P and Q.

INPUT:

- `other` – a poset
- `labels` – either `'integers'` or `'pairs'` (default); how the resulting poset will be labeled

See also:

`product()`, `ordinal_sum()`

EXAMPLES:

```
sage: P1 = Poset((['a', 'b'], [['a', 'b']]))
sage: P2 = Poset((['c', 'd'], [['c', 'd']]))
sage: P = P1.ordinal_product(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[('a', 'c'), ('a', 'd')], [('a', 'd'), ('b', 'c')],
[('b', 'c'), ('b', 'd')]]
```

TESTS:

```
sage: P1.ordinal_product(24)
Traceback (most recent call last):
...
ValueError: the input is not a finite poset
sage: P1.ordinal_product(P2, labels='camembert')
Traceback (most recent call last):
...
ValueError: labels must be either 'pairs' or 'integers'
```

ordinal_sum(*other*, *labels='pairs'*)

Return a poset or (semi)lattice isomorphic to ordinal sum of the poset with `other`.

The ordinal sum of P and Q is a poset that contains every element and relation from both P and Q, and where every element of P is smaller than every element of Q.

Mathematically, it is only defined when P and Q have no common element; here we force that by giving them different names in the resulting poset.

The ordinal sum on lattices is lattice; resp. for meet- and join-semilattices. Hence we check if we can return (semi)lattice instead of plain poset.

INPUT:

- `other`, a poset.
- `labels` - (defaults to 'pairs') If set to 'pairs', each element `v` in this poset will be named `(0,v)` and each element `u` in `other` will be named `(1,u)` in the result. If set to 'integers', the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

```
sage: P1 = Poset( ([1, 2, 3, 4], [[1, 2], [1, 3], [1, 4]]) )
sage: P2 = Poset( ([1, 2, 3,], [[2,1], [3,1]]) )
sage: P3 = P1.ordinal_sum(P2); P3
Finite poset containing 7 elements
sage: len(P1.maximal_elements())*len(P2.minimal_elements())
6
sage: len(P1.cover_relations()+P2.cover_relations())
5
sage: len(P3.cover_relations()) # Every element of P2 is greater than elements of P1.
11
sage: P3.list()  # random
[(0, 1), (0, 2), (0, 4), (0, 3), (1, 2), (1, 3), (1, 1)]
sage: P4 = P1.ordinal_sum(P2, labels='integers')
sage: P4.list()  # random
[0, 1, 2, 3, 5, 6, 4]
```

Return type depends on input types:

```
sage: P = Poset({1:[2]}); P
Finite poset containing 2 elements
sage: JL = JoinSemilattice({1:[2]}); JL
Finite join-semilattice containing 2 elements
sage: L = LatticePoset({1:[2]}); L
Finite lattice containing 2 elements
sage: P.ordinal_sum(L)
Finite poset containing 4 elements
sage: L.ordinal_sum(JL)
Finite join-semilattice containing 4 elements
sage: L.ordinal_sum(L)
Finite lattice containing 4 elements
```

See also:

`ordinal_summands()`, `disjoint_union()`, `ordinal_product()`

ordinal_summands()

Return the ordinal summands of the poset as subposets.

The ordinal summands of a poset P is the longest list of non-empty subposets $P_1, \ldots, P_n$ whose ordinal sum is P. This decomposition is unique.

See also:

`ordinal_sum()`

EXAMPLES:

```
sage: P = Poset({'a': ['c', 'd'], 'b': ['d'], 'c': ['x', 'y'],
....: 'd': ['x', 'y']})
sage: parts = P.ordinal_summands(); parts
[Finite poset containing 4 elements, Finite poset containing 2 elements]
sage: sorted(parts[0])
['a', 'b', 'c', 'd']
```

```
sage: Q = parts[0].ordinal_sum(parts[1])
sage: Q.is_isomorphic(P)
True
```

ALGORITHM:

Suppose that a poset P is the ordinal sum of posets L and U. Then P contains maximal antichains l and u such that every element of u covers every element of l; they correspond to maximal elements of L and minimal elements of U.

We consider a linear extension $x_1, \ldots, x_n$ of the poset's elements.

We keep track of the maximal elements of subposet induced by elements $0, \ldots, x_i$ and minimal elements of subposet induced by elements $x_{i+1}, \ldots, x_n$, incrementing i one by one. We then check if l and u fit the previous description.

TESTS:

```
sage: Poset().ordinal_summands()
[Finite poset containing 0 elements]
sage: Poset({1: []}).ordinal_summands()
[Finite poset containing 1 elements]
```

p_partition_enumerator(*tup*, *R*, *check=False*)

Return a P-partition enumerator of `self`.

Given a total order $\prec$ on the elements of a finite poset P (the order of P and the total order $\prec$ can be unrelated; in particular, the latter does not have to extend the former), a P-partition enumerator is the quasisymmetric function $\sum_f \prod_{p \in P} x_{f(p)}$, where the first sum is taken over all P-partitions f.

A P-partition is a function $f : P \to \{1, 2, 3, ...\}$ satisfying the following properties for any two elements i and j of P satisfying $i <_P j$:

- if $i \prec j$ then $f(i) \leq f(j)$,
- if $j \prec i$ then $f(i) < f(j)$.

INPUT:

- `tup` – the tuple containing all elements of P (each of them exactly once), in the order dictated by the total order $\prec$
- `R` – a commutative ring

OUTPUT:

The P-partition enumerator of `self` according to `tup` in the algebra $QSym$ of quasisymmetric functions over the base ring R.

EXAMPLES:

```
sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition_enumerator((3,1,2,4), QQ, check=True); FP
2*M[1, 1, 1, 1] + 2*M[1, 2, 1] + M[2, 1, 1] + M[3, 1]

sage: expansion = FP.expand(5)
sage: xs = expansion.parent().gens()
sage: expansion == sum([xs[a]*xs[b]*xs[c]*xs[d] for a in range(5) for b in range(5) for c in
True

sage: P = Poset([[],[]])
sage: FP = P.p_partition_enumerator((), QQ, check=True); FP
M[]
```

plot(*label_elements=True*, *element_labels=None*, *layout='acyclic'*, *cover_labels=None*, ***kwds*)

Return a Graphic object for the Hasse diagram of the poset.

If the poset is ranked, the plot uses the rank function for the heights of the vertices.

INPUT:

- `label_elements` (default: `True`) - whether to display element labels
- `element_labels` (default: `None`) - a dictionary of element labels
- `cover_labels` - a dictionary, list or function representing labels of the covers of `self`. When set to `None` (default) no label is displayed on the edges of the Hasse Diagram.
- `layout` – the type of layout used to display the Diagram. Set to `'acyclic'` by default (see `GenericGraph.plot` for more information).

Note: All options of `GenericGraph.plot` are also available through this function.

EXAMPLES:

```
sage: D = Poset({ 1:[2,3], 2:[4], 3:[4,5] })
sage: D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
sage: D.plot()
Graphics object consisting of 11 graphics primitives
sage: type(D.plot())
<class 'sage.plot.graphics.Graphics'>
sage: elm_labs = {1:'a', 2:'b', 3:'c', 4:'d', 5:'e'}
sage: D.plot(element_labels=elm_labs)
Graphics object consisting of 11 graphics primitives
```

Plot of a ranked poset:

```
sage: P = Poset(DiGraph('E@ACA@?'))
sage: P.is_ranked()
True
sage: P.plot()
Graphics object consisting of 12 graphics primitives
```

The keyword `cover_labels` can be used to decorate edges:

```
sage: P = posets.ChainPoset(3)
sage: P.plot(cover_labels=lambda a, b: a + b)
Graphics object consisting of 8 graphics primitives
sage: P = Poset({0: [1,2]})
sage: P.plot(cover_labels={(0,1): 'here', (0,2): 'there'})
Graphics object consisting of 8 graphics primitives
sage: P = Poset({2: [1], 0: [1]})
sage: P.plot(cover_labels=[(2,1,'da'), (0,1,'niet')])
Graphics object consisting of 8 graphics primitives
```

TESTS:

We check that `label_elements` and `element_labels` are honored:

```
sage: def get_plot_labels(P): return sorted(t.string for t in P if isinstance(t, sage.plot.t
sage: P1 = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: P2 = Poset({ 0:[1,2], 1:[3], 2:[3,4] }, facade=True)
sage: get_plot_labels(P1.plot(label_elements=False))
```

```
[]
sage: get_plot_labels(P1.plot(label_elements=True))
['0', '1', '2', '3', '4']
sage: element_labels = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: get_plot_labels(P1.plot(element_labels=element_labels))
['a', 'b', 'c', 'd', 'e']
sage: get_plot_labels(P2.plot(element_labels=element_labels))
['a', 'b', 'c', 'd', 'e']
```

The following checks that trac ticket #18936 has been fixed and labels still work:

```
sage: P = Poset({0: [1,2], 1:[3]})
sage: heights = {1 : [0], 2 : [1], 3 : [2,3]}
sage: P.plot(heights=heights)
Graphics object consisting of 8 graphics primitives
sage: elem_labels = {0 : 'a', 1 : 'b', 2 : 'c', 3 : 'd'}
sage: P.plot(element_labels=elem_labels, heights=heights)
Graphics object consisting of 8 graphics primitives
```

Plot of the empy poset:

```
sage: P = Poset({})
sage: P.plot()
Graphics object consisting of 0 graphics primitives
```

product (*other*)

Return the Cartesian product of the poset with `other`.

The Cartesian (or 'direct') product of P and Q is defined by $(p, q) \leq (p', q')$ iff $p \leq p'$ in P and $q \leq q'$ in Q.

Product of (semi)lattices are returned as a (semi)lattice.

EXAMPLES:

```
sage: P = Posets.ChainPoset(3)
sage: Q = Posets.ChainPoset(4)
sage: PQ = P.product(Q) ; PQ
Finite lattice containing 12 elements
sage: len(PQ.cover_relations())
17
sage: Q.product(P).is_isomorphic(PQ)
True

sage: P = Posets.BooleanLattice(2)
sage: Q = P.product(P)
sage: Q.is_isomorphic(Posets.BooleanLattice(4))
True
```

TESTS:

```
sage: Poset({0:[1]}).product(Poset())  # Product with empty poset
Finite poset containing 0 elements
```

We check that trac ticket #19113 is fixed:

```
sage: L = LatticePoset({1:[]})
sage: type(L) == type(L.product(L))
True
```

promotion(*i=1*)

Compute the (extended) promotion on the linear extension of the poset `self`.

INPUT:

- `i` – an integer between 1 and n (default: 1)

OUTPUT:

- an isomorphic poset, with the same default linear extension

The extended promotion is defined on a poset `self` of size n by applying the promotion operator $\tau_i\tau_{i+1}\cdots\tau_{n-1}$ to the default linear extension π of `self` (see `promotion()`), and relabeling `self` accordingly. For more details see [Stan2009].

When the vertices of the poset `self` are labelled by $\{1, 2, \ldots, n\}$, the linear extension is the identity, and $i = 1$, the above algorithm corresponds to the promotion operator on posets defined by Schützenberger as follows. Remove 1 from `self` and replace it by the minimum j of all labels covering 1 in the poset. Then, remove j and replace it by the minimum of all labels covering j, and so on. This process ends when a label is a local maximum. Place the label $n + 1$ at this vertex. Finally, decrease all labels by 1.

EXAMPLES:

```
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.promotion()
Finite poset containing 2 elements with distinguished linear extension
sage: P == P.promotion()
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```

Note that if one wants to obtain the promotion defined by Schützenberger's algorithm directly on the poset, one needs to make sure the linear extension is the identity:

```
sage: P = P.with_linear_extension([1,2,3,4,5,6,7])
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 4], [3, 5], [4, 5], [6, 7]]
sage: Q = P.promotion()
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 5], [3, 6], [4, 7], [5, 7]]
```

Here is an example for a poset not labelled by $\{1, 2, \ldots, n\}$:

```
sage: P = Poset((divisors(30), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 5, 6, 10, 15, 30]
sage: P.cover_relations()
[[1, 2], [1, 3], [1, 5], [2, 6], [2, 10], [3, 6], [3, 15],
 [5, 10], [5, 15], [6, 30], [10, 30], [15, 30]]
sage: Q = P.promotion(4); Q
Finite poset containing 8 elements with distinguished linear extension
sage: Q.cover_relations()
```

```
[[1, 2], [1, 3], [1, 6], [2, 5], [2, 15], [3, 5], [3, 10],
 [5, 30], [6, 10], [6, 15], [10, 30], [15, 30]]
```

- with_linear_extension() and the linear_extension option of Poset()
- promotion()
- evacuation()

AUTHOR:

- Anne Schilling (2012-02-18)

random_order_ideal(*direction='down'*)

Return a random order ideal with uniform probability.

INPUT:

- direction – 'up','down' or 'antichain' (default: 'down')

OUTPUT:

A randomly selected order ideal (or order filter if direction='up', or antichain if direction='antichain') where all order ideals have equal probability of occurring.

ALGORITHM:

Uses the coupling from the past algorithm described in [Propp1997].

EXAMPLES:

```
sage: P = Posets.BooleanLattice(3)
sage: P.random_order_ideal()
[0, 1, 2, 3, 4, 5, 6]
sage: P.random_order_ideal(direction='up')
[6, 7]
sage: P.random_order_ideal(direction='antichain')
[1, 2]

sage: P = posets.TamariLattice(5)
sage: a = P.random_order_ideal('antichain')
sage: P.is_antichain_of_poset(a)
True
sage: a = P.random_order_ideal('up')
sage: P.is_order_filter(a)
True
sage: a = P.random_order_ideal('down')
sage: P.is_order_ideal(a)
True
```

REFERENCES:

random_subposet(*p*)

Return a random subposet that contains each element with probability p.

EXAMPLES:

```
sage: P = Posets.BooleanLattice(3)
sage: set_random_seed(0)
sage: Q = P.random_subposet(0.5)
sage: Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]
```

rank(*element=None*)

Return the rank of an element `element` in the poset `self`, or the rank of the poset if `element` is `None`.

(The rank of a poset is the length of the longest chain of elements of the poset.)

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: P.rank(5)
2
sage: P.rank()
3
sage: Q = Poset([[1,2],[3],[],[]])

sage: P = Posets.SymmetricGroupBruhatOrderPoset(4)
sage: [(v,P.rank(v)) for v in P]
[('1234', 0),
 ('1243', 1),
...
 ('4312', 5),
 ('4321', 6)]
```

rank_function()

Return the (normalized) rank function of the poset, if it exists.

A *rank function* of a poset P is a function r that maps elements of P to integers and satisfies: $r(x) = r(y) + 1$ if x covers y. The function r is normalized such that its minimum value on every connected component of the Hasse diagram of P is 0. This determines the function r uniquely (when it exists).

OUTPUT:

- a lambda function, if the poset admits a rank function
- `None`, if the poset does not admit a rank function

EXAMPLES:

```
sage: P = Poset(([1,2,3,4],[[1,4],[2,3],[3,4]]), facade=True)
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade=True)
sage: P.rank_function() is not None
False
sage: P = Poset(([1,2,3,4,5,6,7,8],[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade=True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

TESTS:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: r = P.rank_function()
```

```
sage: for u,v in P.cover_relations_iterator():
....:     if r(v) != r(u) + 1:
....:         print "Bug in rank_function!"

sage: Q = Poset([[1,2],[4],[3],[4],[]])
sage: Q.rank_function() is None
True
```

relabel(*relabeling*)

Return a copy of this poset with its elements relabelled.

INPUT:

- `relabeling` – a function or dictionary

This function should map each (non-wrapped) element of `self` to some distinct object.

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True, facade = False)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.relabel(lambda x: 12/x)
sage: Q.list()
[12, 6, 4, 3, 2, 1]
sage: Q.cover_relations()
[[12, 6], [12, 4], [6, 3], [6, 2], [4, 2], [3, 1], [2, 1]]
```

Here we relabel the elements of a poset by $\{0, 1, 2, ...\}$, using a dictionary:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True, facade=False)
sage: relabeling = {c.element:i for (i,c) in enumerate(P)}; relabeling
{1: 0, 2: 1, 3: 2, 4: 3, 6: 4, 12: 5}
sage: Q = P.relabel(relabeling)
sage: Q.list()
[0, 1, 2, 3, 4, 5]
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [1, 4], [2, 4], [3, 5], [4, 5]]
```

Mind the `c.element`; this is because the relabeling is applied to the elements of the poset without the wrapping. Thanks to this convention, the same relabeling function can be used both for facade or non facade posets:

```
sage: P = Poset((divisors(12), attrcall("divides")), facade = True, linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: Q = P.relabel(lambda x: 12/x)
sage: Q.list()
[12, 6, 4, 3, 2, 1]
sage: Q.cover_relations()
[[12, 6], [12, 4], [6, 3], [6, 2], [4, 2], [3, 1], [2, 1]]
```

Relabeling a (semi)lattice gives a (semi)lattice:

sage: P=JoinSemilattice({0:[1]}) sage: type(P.relabel(lambda n: n+1)) <class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>

Note: As can be seen in the above examples, the default linear extension of `Q` is that of `P` after relabeling.

In particular, P and Q share the same internal Hasse diagram.

TESTS:

The following checks that trac ticket #14019 has been fixed:

```
sage: d = DiGraph({2:[1],3:[1]})
sage: p1 = Poset(d)
sage: p2 = p1.relabel({1:1,2:3,3:2})
sage: p1.hasse_diagram() == p2.hasse_diagram()
True
sage: p1 == p2
True

sage: d = DiGraph({2:[1],3:[1]})
sage: p1 = Poset(d)
sage: p2 = p1.relabel({1:2,2:3,3:1})
sage: p3 = p2.relabel({2:1,1:2,3:3})
sage: p1.hasse_diagram() == p3.hasse_diagram()
True
sage: p1 == p3
True
```

relations()

Return the list of all relations of the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

The number of relations is the dimension of the incidence algebra.

OUTPUT:

A list of pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

See also:

relations_number(), relations_iterator()

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.relations()
[[1, 1], [1, 2], [1, 3], [1, 4], [0, 0], [0, 2], [0, 3],
[0, 4], [2, 2], [2, 3], [2, 4], [3, 3], [3, 4], [4, 4]]
```

TESTS:

```
sage: P = Poset()  # Test empty poset
sage: P.relations()
[]
```

AUTHOR:

- Rob Beezer (2011-05-04)

relations_iterator(*strict=False*)

Return an iterator for all the relations of the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

INPUT:

- `strict` – a boolean (default `False`) if `True`, returns an iterator over relations $x < y$, excluding all relations $x \leq x$.

OUTPUT:

A generator that produces pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

See also:

`relations_number()`, `relations()`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: it = P.relations_iterator()
sage: type(it)
<type 'generator'>
sage: it.next(), it.next()
([1, 1], [1, 2])

sage: P = posets.PentagonPoset()
sage: list(P.relations_iterator(strict=True))
[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```

AUTHOR:

- Rob Beezer (2011-05-04)

relations_number()

Return the number of relations in the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

See also:

`relations_iterator()`, `relations()`

EXAMPLES:

```
sage: P = Posets.PentagonPoset()
sage: P.relations_number()
13

sage: from sage.combinat.tamari_lattices import TamariLattice
sage: TamariLattice(4).relations_number()
68
```

TESTS:

```
sage: Poset().relations_number()
0
```

show(*label_elements=True*, *element_labels=None*, *cover_labels=None*, ***kwds*)

Displays the Hasse diagram of the poset.

INPUT:

- `label_elements` (default: `True`) - whether to display element labels
- `element_labels` (default: `None`) - a dictionary of element labels

- `cover_labels` - a dictionary, list or function representing labels of the covers of `self`. When set to `None` (default) no label is displayed on the edges of the Hasse Diagram.

Note: This method also accepts:

- All options of `GenericGraph.plot`
- All options of `Graphics.show`

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
sage: D.show()
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.show(element_labels=elm_labs)
```

One more example with cover labels:

```
sage: P = posets.PentagonPoset()
sage: P.show(cover_labels=lambda a, b: a - b)
```

subposet(*elements*)

Return the poset containing elements with partial order induced by that of `self`.

EXAMPLES:

```
sage: P = Poset({"a":["c","d"], "b":["d","e"], "c":["f"], "d":["f"], "e":["f"]}, facade = Fa
sage: Q = P.subposet(["a","b","f"]); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[[b, f], [a, f]]
```

A subposet of a facade poset is again a facade poset:

```
sage: P = Poset({"a":["c","d"], "b":["d","e"], "c":["f"], "d":["f"], "e":["f"]}, facade=True
sage: Q = P.subposet(["a","b","f"]); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[['b', 'f'], ['a', 'f']]
```

One may specified wrapped elements or not:

```
sage: P = Poset({"a":["c","d"], "b":["d","e"], "c":["f"], "d":["f"], "e":["f"]}, facade = Fa
sage: Q = P.subposet([P("a"),P("b"),P("f")]); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[[b, f], [a, f]]

sage: B = posets.BooleanLattice(2)
sage: above = B.principal_order_filter(0)
sage: Q = B.subposet(above)
sage: above_new = Q.principal_order_filter(Q.list()[0])
sage: Q.subposet(above_new)
Finite poset containing 4 elements
```

TESTS:

```
sage: P.subposet(("a","b","f"))
Finite poset containing 3 elements
```

```
sage: P.subposet(["a","b","x"])
Traceback (most recent call last):
...
ValueError: <type 'str'> is not an element of this poset
sage: P.subposet(3)
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

to_graph(**args*, ***kwds*)

Deprecated: Use `cover_relations_graph()` instead. See trac ticket #17449 for details.

top()

Return the unique maximal element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1
```

See also:

`has_top()`, `bottom()`

TESTS:

```
sage: R = Poset([[0],[]])
sage: R.list()
[0]
sage: R.top() #Trac #10776
0
```

unwrap(*element*)

Return the element `element` of the poset `self` in unwrapped form.

INPUT:

- `element` – an element of `self`

EXAMPLES:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: x = P.an_element(); x
1
sage: x.parent()
Finite poset containing 4 elements
sage: P.unwrap(x)
1
sage: P.unwrap(x).parent()
Integer Ring
```

For a non facade poset, this is equivalent to using the `.element` attribute:

```
sage: P.unwrap(x) is x.element
True
```

For a facade poset, this does nothing:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: x = P.an_element()
sage: P.unwrap(x) is x
True
```

This method is useful in code where we don't know if `P` is a facade poset or not.

upper_covers(*x*)
Return the list of upper covers of the element `x`.

An upper cover of x is an element y such that $x < y$ and there is no element z so that $x < z < y$.

EXAMPLES:

```
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.upper_covers(1)
[2, 6]
```

See also:

`lower_covers()`

upper_covers_iterator(*x*)
Return an iterator over the upper covers of the element `x`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
sage: type(P.upper_covers_iterator(0))
<type 'generator'>
```

width()
Return the width of the poset (the size of its longest antichain).

It is computed through a matching in a bipartite graph; see Wikipedia article Dilworth's_theorem for more information. The width is also called Dilworth number.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.width()
6
```

TESTS:

```
sage: Poset().width()
0
```

with_bounds(*labels=('bottom', 'top')*)
Return the poset with bottom and top elements adjoined.

This functions always adds two new elements to the poset, i.e. it does not check if the poset already has a bottom or a top element.

For lattices and semilattices this function returns a lattice.

INPUT:

- `labels` – A pair of elements to use as a bottom and top element of the poset. Default is strings `'bottom'` and `'top'`.

EXAMPLES:

```
sage: V = Poset({0: [1, 2]})
sage: trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements
sage: trafficsign.list()
['bottom', 0, 1, 2, 'top']
sage: trafficsign = V.with_bounds(labels=(-1, -2))
sage: trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]

sage: P = Posets.PentagonPoset()  # A lattice
sage: P.with_bounds()
Finite lattice containing 7 elements
```

TESTS:

```
sage: P = Poset().with_bounds()
sage: P.cover_relations()
[['bottom', 'top']]

sage: LatticePoset({}).with_bounds()
Finite lattice containing 2 elements

sage: Posets.PentagonPoset().with_bounds(labels=(4, 5))
Traceback (most recent call last):
...
ValueError: the poset already has element 4
```

with_linear_extension(*linear_extension*)

Return a copy of `self` with a different default linear extension.

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: list(P)
[1, 2, 3, 4, 6, 12]
sage: Q = P.with_linear_extension([1,3,2,6,4,12])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

TESTS:

We check that we can pass in a list of elements of `P` instead:

```
sage: Q = P.with_linear_extension([P(_) for _ in [1,3,2,6,4,12]])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

We check that this works for facade posets too:

```
sage: P = Poset((divisors(12), attrcall("divides")), facade=True)
sage: Q = P.with_linear_extension([1,3,2,6,4,12])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
```

```
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
sage: sorted(Q.cover_relations()) == sorted(P.cover_relations())
True
```

Note: With the current implementation, this requires relabeling the internal `DiGraph` which is $O(n+m)$, where n is the number of elements and m the number of cover relations.

---

zeta_polynomial()

Return the zeta polynomial of the poset `self`.

The zeta polynomial of a poset is the unique polynomial $Z(q)$ such that for every integer $m > 1$, $Z(m)$ is the number of weakly increasing sequences $x_1 \leq x_2 \leq \cdots \leq x_{m-1}$ of elements of the poset.

The polynomial $Z(q)$ is integral-valued, but generally doesn't have integer coefficients. It can be computed as

$$Z(q) = \sum_{k \geq 1} \binom{q-2}{k-1} c_k,$$

where c_k is the number of all chains of length k in the poset.

For more information, see section 3.12 of [EnumComb1].

In particular, $Z(2)$ is the number of vertices and $Z(3)$ is the number of intervals.

EXAMPLES:

```
sage: Posets.ChainPoset(2).zeta_polynomial()
q
sage: Posets.ChainPoset(3).zeta_polynomial()
1/2*q^2 + 1/2*q
sage: P = posets.PentagonPoset()
sage: P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q
sage: P = Posets.DiamondPoset(5)
sage: P.zeta_polynomial()
3/2*q^2 - 1/2*q
```

TESTS:

Checking the simplest cases:

```
sage: Poset({}).zeta_polynomial()
0
sage: Poset({1: []}).zeta_polynomial()
1
sage: Poset({1: [], 2: []}).zeta_polynomial()
2
```

class sage.combinat.posets.posets.**FinitePosets_n**(n)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The finite enumerated set of all posets on n vertices, up to an isomorphism.

EXAMPLES:

```
sage: P = Posets(3)
sage: P.cardinality()
5
sage: for p in P: print p.cover_relations()
```

```
[]
[[1, 2]]
[[0, 1], [0, 2]]
[[0, 1], [1, 2]]
[[1, 2], [0, 2]]
```

cardinality(*from_iterator=False*)

Return the cardinality of this object.

Note: By default, this returns pre-computed values obtained from the On-Line Encyclopedia of Integer Sequences (OEIS sequence A000112). To override this, pass the argument `from_iterator=True`.

EXAMPLES:

```
sage: P = Posets(3)
sage: P.cardinality()
5
sage: P.cardinality(from_iterator=True)
5
```

sage.combinat.posets.posets.**Poset**(*data=None*, *element_labels=None*, *cover_relations=False*, *linear_extension=False*, *category=None*, *facade=None*, *key=None*)

Construct a finite poset from various forms of input data.

INPUT:

- `data` – different input are accepted by this constructor:

  1. A two-element list or tuple `(E, R)`, where `E` is a collection of elements of the poset and `R` is a collection of relations `x <= y`, each represented as a two-element list/tuple/iterable such as `[x, y]`. The poset is then the transitive closure of the provided relations. If `cover_relations=True`, then `R` is assumed to contain exactly the cover relations of the poset. If `E` is empty, then `E` is taken to be the set of elements appearing in the relations `R`.

  2. A two-element list or tuple `(E, f)`, where `E` is the set of elements of the poset and `f` is a function such that, for any pair `x, y` of elements of `E`, `f(x, y)` returns whether `x <= y`. If `cover_relations=True`, then `f(x, y)` should instead return whether `x` is covered by `y`.

  3. A dictionary, list or tuple of upper covers: `data[x]` is a list of the elements that cover the element x in the poset.

     Warning: If data is a list or tuple of length 2, then it is handled by the above case..

  4. An acyclic, loop-free and multi-edge free `DiGraph`. If `cover_relations` is `True`, then the edges of the digraph are assumed to correspond to the cover relations of the poset. Otherwise, the cover relations are computed.

  5. A previously constructed poset (the poset itself is returned).

- `element_labels` – (default: `None`); an optional list or dictionary of objects that label the poset elements.

- `cover_relations` – a boolean (default: `False`); whether the data can be assumed to describe a directed acyclic graph whose arrows are cover relations; otherwise, the cover relations are first computed.

- `linear_extension` – a boolean (default: `False`); whether to use the provided list of elements as default linear extension for the poset; otherwise a linear extension is computed. If the data is given as the pair `(E, f)`, then `E` is taken to be the linear extension.

- facade – a boolean or None (default); whether the Poset() 's elements should be wrapped to make them aware of the Poset they belong to.
  - If facade = True, the Poset() 's elements are exactly those given as input.
  - If facade = False, the Poset() 's elements will become PosetElement objects.
  - If facade = None (default) the expected behaviour is the behaviour of facade = True, unless the opposite can be deduced from the context (i.e. for instance if a Poset() is built from another Poset(), itself built with facade = False)

OUTPUT:

FinitePoset – an instance of the FinitePoset class.

If category is specified, then the poset is created in this category instead of FinitePosets.

See also:

Posets, Posets, FinitePosets

EXAMPLES:

1. Elements and cover relations:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: Poset((elms, rels), cover_relations = True, facade = False)
Finite poset containing 7 elements
```

Elements and non-cover relations:

```
sage: elms = [1,2,3,4]
sage: rels = [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
sage: P = Poset( [elms,rels] ,cover_relations=False); P
Finite poset containing 4 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [3, 4]]
```

2. Elements and function: the standard permutations of [1, 2, 3, 4] with the Bruhat order:

```
sage: elms = Permutations(4)
sage: fcn = lambda p,q : p.bruhat_lequal(q)
sage: Poset((elms, fcn))
Finite poset containing 24 elements
```

With a function that identifies the cover relations: the set partitions of $\{1, 2, 3\}$ ordered by refinement:

```
sage: elms = SetPartitions(3)
sage: def fcn(A, B):
....:     if len(A) != len(B)+1:
....:         return False
....:     for a in A:
....:         if not any(set(a).issubset(b) for b in B):
....:             return False
....:     return True
sage: Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements
```

3.A dictionary of upper covers:

```
sage: Poset({'a':['b','c'], 'b':['d'], 'c':['d'], 'd':[]})
Finite poset containing 4 elements
```

A list of upper covers:

```
sage: Poset([[1,2],[4],[3],[4],[]])
Finite poset containing 5 elements
```

A list of upper covers and a dictionary of labels:

```
sage: elm_labs = {0:"a",1:"b",2:"c",3:"d",4:"e"}
sage: P = Poset([[1,2],[4],[3],[4],[]], elm_labs, facade = False)
sage: P.list()
[a, b, c, d, e]
```

Warning: The special case where the argument data is a list or tuple of length 2 is handled by the above cases. So you cannot use this method to input a 2-element poset.

4.An acyclic DiGraph.

```
sage: dag = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: Poset(dag)
Finite poset containing 6 elements
```

Any directed acyclic graph without loops or multiple edges, as long as `cover_relations=False`:

```
sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: dig.allows_multiple_edges()
False
sage: dig.allows_loops()
False
sage: dig.transitive_reduction() == dig
False
sage: Poset(dig, cover_relations=False)
Finite poset containing 6 elements
sage: Poset(dig, cover_relations=True)
Traceback (most recent call last):
...
ValueError: Hasse diagram is not transitively reduced.
```

Default Linear extension

Every poset P obtained with `Poset` comes equipped with a default linear extension, which is also used for enumerating its elements. By default, this linear extension is computed, and has no particular significance:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: P.list()
[1, 2, 4, 3, 6, 12]
sage: P.linear_extension()
[1, 2, 4, 3, 6, 12]
```

You may enforce a specific linear extension using the `linear_extension` option:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.linear_extension()
[1, 2, 3, 4, 6, 12]
```

Depending on popular request, `Poset` might eventually get modified to always use the provided list of elements as default linear extension, when it is one.

See also:

`FinitePoset.linear_extensions()`

Facade posets

When `facade = False`, the elements of a poset are wrapped so as to make them aware that they belong to that poset:

```
sage: P = Poset(DiGraph({'d':['c','b'],'c':['a'],'b':['a']}), facade = False)
sage: d,c,b,a = list(P)
sage: a.parent() is P
True
```

This allows for comparing elements according to P:

```
sage: c < a
True
```

However, this may have surprising effects:

```
sage: my_elements = ['a','b','c','d']
sage: any(x in my_elements for x in P)
False
```

and can be annoying when one wants to manipulate the elements of the poset:

```
sage: a + b
Traceback (most recent call last):
...
TypeError: unsupported operand type(s) for +: 'FinitePoset_with_category.element_class' and 'Fin
sage: a.element + b.element
'ab'
```

By default, facade posets are constructed instead:

```
sage: P = Poset(DiGraph({'d':['c','b'],'c':['a'],'b':['a']}))
```

In this example, the elements of the poset remain plain strings:

```
sage: d,c,b,a = list(P)
sage: type(a)
<type 'str'>
```

Of course, those strings are not aware of P. So to compare two such strings, one needs to query P:

```
sage: a < b
True
sage: P.lt(a,b)
False
```

which models the usual mathematical notation $a <_P b$.

Most operations seem to still work, but at this point there is no guarantee whatsoever:

```
sage: P.list()
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('a')
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('b')
['d', 'b']
sage: P.principal_order_ideal('d')
['d']
sage: TestSuite(P).run()
```

Warning: `DiGraph` is used to construct the poset, and the vertices of a `DiGraph` are converted to plain Python `int`'s if they are `Integer`'s:

```
sage: G = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: type(G.vertices()[0])
<type 'int'>
```

This is worked around by systematically converting back the vertices of a poset to `Integer`'s if they are `int`'s:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: type(P.an_element().element)
<type 'sage.rings.integer.Integer'>

sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: type(P.an_element())
<type 'sage.rings.integer.Integer'>
```

This may be abusive:

```
sage: P = Poset((range(5), operator.le), facade = True)
sage: P.an_element().parent()
Integer Ring
```

Unique representation

As most parents, `Poset` have unique representation (see `UniqueRepresentation`). Namely if two posets are created from two equal data, then they are not only equal but actually identical:

```
sage: data1 = [[1,2],[3],[3]]
sage: data2 = [[1,2],[3],[3]]
sage: P1 = Poset(data1)
sage: P2 = Poset(data2)
sage: P1 == P2
True
```

```
sage: P1 is P2
True
```

In situations where this behaviour is not desired, one can use the `key` option:

```
sage: P1 = Poset(data1, key = "foo")
sage: P2 = Poset(data2, key = "bar")
sage: P1 is P2
False
sage: P1 == P2
False
```

`key` can be any hashable value and is passed down to `UniqueRepresentation`. It is otherwise ignored by the poset constructor.

TESTS:

```
sage: P = Poset([[1,2],[3],[3]])
sage: type(hash(P))
<type 'int'>
```

Bad input:

```
sage: Poset([1,2,3], lambda x,y : x<y)
Traceback (most recent call last):
...
ValueError: element_labels should be a dict or a list if different
from None. (Did you intend data to be equal to a pair ?)
```

Another kind of bad input, digraphs with oriented cycles:

```
sage: Poset(DiGraph([[1,2],[2,3],[3,4],[4,1]]))
Traceback (most recent call last):
...
ValueError: The graph is not directed acyclic
```

sage.combinat.posets.posets.**is_poset**(*dig*)

Return `True` if a directed graph is acyclic and transitively reduced, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.posets import is_poset
sage: dig = DiGraph({0:[2, 3], 1:[3, 4, 5], 2:[5], 3:[5], 4:[5]})
sage: is_poset(dig)
False
sage: is_poset(dig.transitive_reduction())
True
```

5.1.160 q-Analogues

sage.combinat.q_analogues.**gaussian_binomial**(*n*, *k*, *q=None*, *algorithm='auto'*)

This is an alias of `q_binomial()`.

See `q_binomial()` for the full documentation.

EXAMPLES:

```
sage: gaussian_binomial(4,2)
q^4 + q^3 + 2*q^2 + q + 1
```

sage.combinat.q_analogues.**gaussian_multinomial**(*seq*, *q=None*, *binomial_algorithm='auto'*)

Return the q-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

$$\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q![k_2]_q! \cdots [k_m]_q!}$$

where $n = k_1 + k_2 + \cdots + k_m$.

If q is unspecified, then the variable is the generator q for a univariate polynomial ring over the integers.

INPUT:

- `seq` – an iterable of the values k_1 to k_m defined above
- `q` – (default: `None`) the variable q; if `None`, then use a default variable in $\mathbf{Z}[q]$
- `binomial_algorithm` – (default: `'auto'`) the algorithm to use in `q_binomial()`; see possible values there

ALGORITHM:

We use the equivalent formula

$$\binom{k_1 + \cdots + k_m}{k_1, \ldots, k_m}_q = \prod_{i=1}^{m} \binom{\sum_{j=1}^{i} k_j}{k_i}_q.$$

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1,2,1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial([1,2,1], q=1) == multinomial([1,2,1])
True
sage: q_multinomial((3,2)) == q_binomial(5,3)
True
sage: q_multinomial([])
1
```

sage.combinat.q_analogues.**q_binomial**(*n*, *k*, *q=None*, *algorithm='auto'*)

Return the q-binomial coefficient.

This is also known as the Gaussian binomial coefficient, and is defined by

$$\binom{n}{k}_q = \frac{(1-q^n)(1-q^{n-1}) \cdots (1-q^{n-k+1})}{(1-q)(1-q^2) \cdots (1-q^k)}.$$

See Wikipedia article Gaussian_binomial_coefficient.

If q is unspecified, then the variable is the generator q for a univariate polynomial ring over the integers.

INPUT:

- `n, k` – the values n and k defined above
- `q` – (default: `None`) the variable q; if `None`, then use a default variable in $\mathbf{Z}[q]$
- `algorithm` – (default: `'auto'`) the algorithm to use and can be one of the following:
  - `'auto'` – automatically choose the algorithm; see the algorithm section below
  - `'naive'` – use the naive algorithm

– 'cyclotomic' – use cyclotomic algorithm

ALGORITHM:

The naive algorithm uses the product formula. The cyclotomic algorithm uses a product of cyclotomic polynomials (cf. [CH2006]).

When the algorithm is set to 'auto', we choose according to the following rules:

- If q is a polynomial:

  When n is small or k is small with respect to n, one uses the naive algorithm. When both n and k are big, one uses the cyclotomic algorithm.

- If q is in the symbolic ring, one uses the cyclotomic algorithm.

- Otherwise one uses the naive algorithm, unless q is a root of unity, then one uses the cyclotomic algorithm.

EXAMPLES:

By default, the variable is the generator of $\mathbf{Z}[q]$:

```
sage: from sage.combinat.q_analogues import q_binomial
sage: g = q_binomial(5,1) ; g
q^4 + q^3 + q^2 + q + 1
sage: g.parent()
Univariate Polynomial Ring in q over Integer Ring
```

The q-binomial coefficient vanishes unless $0 \leq k \leq n$:

```
sage: q_binomial(4,5)
0
sage: q_binomial(5,-1)
0
```

Other variables can be used, given as third parameter:

```
sage: p = ZZ['p'].gen()
sage: q_binomial(4,2,p)
p^4 + p^3 + 2*p^2 + p + 1
```

The third parameter can also be arbitrary values:

```
sage: q_binomial(5,1,2) == g.subs(q=2)
True
sage: q_binomial(5,1,1)
5
sage: q_binomial(4,2,-1)
2
sage: q_binomial(4,2,3.14)
152.030056160000
sage: R = GF(25, 't')
sage: t = R.gen(0)
sage: q_binomial(6, 3, t)
2*t + 3
```

We can also do this for more complicated objects such as matrices or symmetric functions:

```
sage: q_binomial(4,2,matrix([[2,1],[-1,3]]))
[ -6  84]
[-84  78]
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: q_binomial(4,1, s[2]+s[1])
```

```
s[] + s[1] + s[1, 1] + s[1, 1, 1] + 2*s[2] + 4*s[2, 1] + 3*s[2, 1, 1]
 + 4*s[2, 2] + 3*s[2, 2, 1] + s[2, 2, 2] + 3*s[3] + 7*s[3, 1] + 3*s[3, 1, 1]
 + 6*s[3, 2] + 2*s[3, 2, 1] + s[3, 3] + 4*s[4] + 6*s[4, 1] + s[4, 1, 1]
 + 3*s[4, 2] + 3*s[5] + 2*s[5, 1] + s[6]
```

TESTS:

One checks that the first two arguments are integers:

```
sage: q_binomial(1/2,1)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

One checks that n is nonnegative:

```
sage: q_binomial(-4,1)
Traceback (most recent call last):
...
ValueError: n must be nonnegative
```

This also works for variables in the symbolic ring:

```
sage: z = var('z')
sage: factor(q_binomial(4,2,z))
(z^2 + z + 1)*(z^2 + 1)
```

This also works for complex roots of unity:

```
sage: q_binomial(6, 1, QQbar(I))
I + 1
```

Note that the symbolic computation works (see trac ticket #14982):

```
sage: q_binomial(6, 1, I)
I + 1
```

Check that the algorithm does not matter:

```
sage: q_binomial(6,3, algorithm='naive') == q_binomial(6,3, algorithm='cyclotomic')
True
```

One more test:

```
sage: q_binomial(4, 2, Zmod(6)(2), algorithm='naive')
5
```

sage.combinat.q_analogues.**q_catalan_number**(*n*, *q=None*)

Returns the q-Catalan number of index n.

If q is unspecified, then it defaults to using the generator q for a univariate polynomial ring over the integers.

There are several q-Catalan numbers. This procedure returns the one which can be written using the q-binomial coefficients.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_catalan_number
sage: q_catalan_number(4)
q^12 + q^10 + q^9 + 2*q^8 + q^7 + 2*q^6 + q^5 + 2*q^4 + q^3 + q^2 + 1
sage: p = ZZ['p'].0
sage: q_catalan_number(4,p)
p^12 + p^10 + p^9 + 2*p^8 + p^7 + 2*p^6 + p^5 + 2*p^4 + p^3 + p^2 + 1
```

The q-Catalan number of index n is only defined for n a nonnegative integer (trac ticket #11411):

```
sage: q_catalan_number(-2)
Traceback (most recent call last):
...
ValueError: Argument (-2) must be a nonnegative integer.
```

sage.combinat.q_analogues.**q_factorial**(*n*, *q=None*)

Returns the q-analogue of the factorial $n!$.

If q is unspecified, then it defaults to using the generator q for a univariate polynomial ring over the integers.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_factorial
sage: q_factorial(3)
q^3 + 2*q^2 + 2*q + 1
sage: p = ZZ['p'].0
sage: q_factorial(3, p)
p^3 + 2*p^2 + 2*p + 1
```

The q-analogue of $n!$ is only defined for n a non-negative integer (trac ticket #11411):

```
sage: q_factorial(-2)
Traceback (most recent call last):
...
ValueError: Argument (-2) must be a nonnegative integer.
```

sage.combinat.q_analogues.**q_int**(*n*, *q=None*)

Return the q-analogue of the integer n.

The q-analogue of the integer n is given by

$$[n]_q = \begin{cases} 1 + q + \cdots + q^{n-1}, & \text{if } n \geq 0, \\ -q^{-n}[-n]_q, & \text{if } n \leq 0. \end{cases}$$

Consequently, if $q = 1$ then $[n]_1 = n$ and if $q \neq 1$ then $[n]_q = (q^n - 1)/(q - 1)$.

If the argument q is not specified then it defaults to the generator q of the univariate polynomial ring over the integers.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_int
sage: q_int(3)
q^2 + q + 1
sage: q_int(-3)
(-q^2 - q - 1)/q^3
sage: p = ZZ['p'].0
sage: q_int(3,p)
p^2 + p + 1
sage: q_int(3/2)
Traceback (most recent call last):
```

```
...
ValueError: 3/2 must be an integer
```

TESTS:

We check that trac ticket #15805 is fixed:

```
sage: from sage.combinat.q_analogues import q_int
sage: q_int(0).parent()
Univariate Polynomial Ring in q over Integer Ring
```

sage.combinat.q_analogues.**q_jordan**(*t*, *q*)

INPUT:

- t – a partition of an integer
- q – an integer or an indeterminate

OUTPUT:

If q is the power of a prime number, the output is the number of complete flags in F_q^N (where N is the size of t) stable under a linear nilpotent endomorphism f whose Jordan type is given by t, i.e. such that for all i:

$$\dim(\ker f^i) = t[0] + \cdots + t[i-1]$$

If q is an indeterminate, the output is a polynomial whose values at powers of prime numbers are the previous numbers.

The result is cached.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_jordan
sage: [q_jordan(mu,2) for mu in Partitions(5)]
[9765, 1029, 213, 93, 29, 9, 1]
sage: [q_jordan(mu,2) for mu in Partitions(6)]
[615195, 40635, 5643, 2331, 1491, 515, 147, 87, 47, 11, 1]

sage: q=PolynomialRing(ZZ,'q').gen()
sage: q_jordan(Partition([3,2,1]),q)
16*q^4 + 24*q^3 + 14*q^2 + 5*q + 1
```

If the partition is trivial (i.e. has only one part), we get the q-factorial (in this case, the nilpotent endomorphism is necessarily 0):

```
sage: from sage.combinat.q_analogues import q_factorial
sage: q_jordan(Partition([5]),3) == q_factorial(5,3)
True
sage: q_jordan(Partition([11]),5) == q_factorial(11,5)
True
```

TESTS:

```
sage: q_jordan(Partition([4,3,1]),1)
Traceback (most recent call last):
...
ValueError: q must not be equal to 1
```

AUTHOR:

- Xavier Caruso (2012-06-29)

sage.combinat.q_analogues.**q_multinomial**(*seq*, *q=None*, *binomial_algorithm='auto'*)

Return the q-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

$$\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q![k_2]_q! \cdots [k_m]_q!}$$

where $n = k_1 + k_2 + \cdots + k_m$.

If q is unspecified, then the variable is the generator q for a univariate polynomial ring over the integers.

INPUT:

- `seq` – an iterable of the values k_1 to k_m defined above
- `q` – (default: `None`) the variable q; if `None`, then use a default variable in $\mathbf{Z}[q]$
- `binomial_algorithm` – (default: `'auto'`) the algorithm to use in `q_binomial()`; see possible values there

ALGORITHM:

We use the equivalent formula

$$\binom{k_1 + \cdots + k_m}{k_1, \ldots, k_m}_q = \prod_{i=1}^{m} \binom{\sum_{j=1}^{i} k_j}{k_i}_q.$$

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1,2,1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial([1,2,1], q=1) == multinomial([1,2,1])
True
sage: q_multinomial((3,2)) == q_binomial(5,3)
True
sage: q_multinomial([])
1
```

sage.combinat.q_analogues.**q_subgroups_of_abelian_group**(*la*, *mu*, *q=None*, *algorithm='birkhoff'*)

Return the q-number of subgroups of type `mu` in a finite abelian group of type `la`.

INPUT:

- `la` – type of the ambient group as a `Partition`
- `mu` – type of the subgroup as a `Partition`
- `q` – (default: `None`) an indeterminat or a prime number; if `None`, this defaults to $q \in \mathbf{Z}[q]$
- `algorithm` – (default: `'birkhoff'`) the algorithm to use can be one of the following:
  - `'birkhoff` – use the Birkhoff formula from [Bu87]
  - `'delsarte'` – use the formula from [Delsarte48]

OUTPUT:

The number of subgroups of type `mu` in a group of type `la` as a polynomial in `q`.

ALGORITHM:

Let q be a prime number and $\lambda = (\lambda_1, \ldots, \lambda_l)$ be a partition. A finite abelian q-group is of type λ if it is isomorphic to

$$\mathbf{Z}/q^{\lambda_1}\mathbf{Z} \times \cdots \times \mathbf{Z}/q^{\lambda_l}\mathbf{Z}.$$

The formula from [Bu87] works as follows: Let λ and μ be partitions. Let λ' and μ' denote the conjugate partitions to λ and μ, respectively. The number of subgroups of type μ in a group of type λ is given by

$$\prod_{i=1}^{\mu_1} q^{\mu'_{i+1}(\lambda'_i - \mu'_i)} \binom{\lambda'_i - \mu'_{i+1}}{\mu'_i - \mu'_{i+1}}_q$$

The formula from [Delsarte48] works as follows: Let λ and μ be partitions. Let $(s_1, s_2, \ldots, s_l)$ and $(r_1, r_2, \ldots, r_k)$ denote the parts of the partitions conjugate to λ and μ respectively. Let

$$\mathfrak{F}(\xi_1, \ldots, \xi_k) = \xi_1^{r_2}\xi_2^{r_3}\cdots\xi_{k-1}^{r_k} \prod_{i_1=r_2}^{r_1-1}(\xi_1 - q^{i_1}) \prod_{i_2=r_3}^{r_2-1}(\xi_2 - q^{i_2}) \cdots \prod_{i_k=0}^{r_k-1}(\xi_k - q^{-i_k}).$$

Then the number of subgroups of type μ in a group of type λ is given by

$$\frac{\mathfrak{F}(q^{s_1}, q^{s_2}, \ldots, q^{s_k})}{\mathfrak{F}(q^{r_1}, q^{r_2}, \ldots, q^{r_k})}.$$

EXAMPLES:

```
sage: from sage.combinat.q_analogues import q_subgroups_of_abelian_group
sage: q_subgroups_of_abelian_group([1,1], [1])
q + 1
sage: q_subgroups_of_abelian_group([3,3,2,1], [2,1])
q^6 + 2*q^5 + 3*q^4 + 2*q^3 + q^2
sage: R.<t> = QQ[]
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], t)
t^4 + 2*t^3 + t^2
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], 3)
144
sage: q_subgroups_of_abelian_group([1,1,1], [1]) == q_subgroups_of_abelian_group([1,1,1], [1,1])
True
sage: q_subgroups_of_abelian_group([5], [3])
1
sage: q_subgroups_of_abelian_group([1], [2])
0
sage: q_subgroups_of_abelian_group([2], [1,1])
0
```

TESTS:

Check the same examples with `algorithm='delsarte'`:

```
sage: q_subgroups_of_abelian_group([1,1], [1], algorithm='delsarte')
q + 1
sage: q_subgroups_of_abelian_group([3,3,2,1], [2,1], algorithm='delsarte')
q^6 + 2*q^5 + 3*q^4 + 2*q^3 + q^2
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], t, algorithm='delsarte')
t^4 + 2*t^3 + t^2
sage: q_subgroups_of_abelian_group([5,3,1], [3,1], 3, algorithm='delsarte')
144
sage: q_subgroups_of_abelian_group([1,1,1], [1], algorithm='delsarte') == q_subgroups_of_abelian
True
sage: q_subgroups_of_abelian_group([5], [3], algorithm='delsarte')
1
```

```
sage: q_subgroups_of_abelian_group([1], [2], algorithm='delsarte')
0
sage: q_subgroups_of_abelian_group([2], [1,1], algorithm='delsarte')
0
```

sage.combinat.q_analogues.**qt_catalan_number**(*n*)

Returns the q,t-Catalan number of index n.

EXAMPLES:

```
sage: from sage.combinat.q_analogues import qt_catalan_number
sage: qt_catalan_number(1)
1
sage: qt_catalan_number(2)
q + t
sage: qt_catalan_number(3)
q^3 + q^2*t + q*t^2 + t^3 + q*t
sage: qt_catalan_number(4)
q^6 + q^5*t + q^4*t^2 + q^3*t^3 + q^2*t^4 + q*t^5 + t^6 + q^4*t + q^3*t^2 + q^2*t^3 + q*t^4 + q^
```

The q,t-Catalan number of index n is only defined for n a nonnegative integer (trac ticket #11411):

```
sage: qt_catalan_number(-2)
Traceback (most recent call last):
...
ValueError: Argument (-2) must be a nonnegative integer.
```

5.1.161 q-Bernoulli Numbers and Polynomials

sage.combinat.q_bernoulli.**q_bernoulli**(*m*, *p=None*)

Compute Carlitz's q-analogue of the Bernoulli numbers.

For every nonnegative integer m, the q-Bernoulli number β_m is a rational function of the indeterminate q whose value at $q = 1$ is the usual Bernoulli number B_m.

INPUT:

- m – a nonnegative integer
- p (default: `None`) – an optional value for q

OUTPUT:

A rational function of the indeterminate q (if p is `None`)

Otherwise, the rational function is evaluated at p.

EXAMPLES:

```
sage: from sage.combinat.q_bernoulli import q_bernoulli
sage: q_bernoulli(0)
1
sage: q_bernoulli(1)
-1/(q + 1)
```

```
sage: q_bernoulli(2)
q/(q^3 + 2*q^2 + 2*q + 1)
sage: all(q_bernoulli(i)(q=1) == bernoulli(i) for i in range(12))
True
```

One can evaluate the rational function by giving a second argument:

```
sage: x = PolynomialRing(GF(2),'x').gen()
sage: q_bernoulli(5,x)
x/(x^6 + x^5 + x + 1)
```

The function does not accept negative arguments:

```
sage: q_bernoulli(-1)
Traceback (most recent call last):
...
ValueError: the argument must be a nonnegative integer
```

REFERENCES:

sage.combinat.q_bernoulli.**q_bernoulli_polynomial**(*m*)

Compute Carlitz's q-analogue of the Bernoulli polynomials.

For every nonnegative integer m, the q-Bernoulli polynomial is a polynomial in one variable x with coefficients in $\mathbf{Q}(q)$ whose value at $q = 1$ is the usual Bernoulli polynomial $B_m(x)$.

The original q-Bernoulli polynomials introduced by Carlitz were polynomials in q^y with coefficients in $\mathbf{Q}(q)$. This function returns these polynomials but expressed in the variable $x = (q^y - 1)/(q - 1)$. This allows to let $q = 1$ to recover the classical Bernoulli polynomials.

INPUT:

- m – a nonnegative integer

OUTPUT:

A polynomial in one variable x.

EXAMPLES:

```
sage: from sage.combinat.q_bernoulli import q_bernoulli_polynomial, q_bernoulli
sage: q_bernoulli_polynomial(0)
1
sage: q_bernoulli_polynomial(1)
(2/(q + 1))*x - 1/(q + 1)
sage: x = q_bernoulli_polynomial(1).parent().gen()
sage: all(q_bernoulli_polynomial(i)(q=1)==bernoulli_polynomial(x,i) for i in range(12))
True
sage: all(q_bernoulli_polynomial(i)(x=0)==q_bernoulli(i) for i in range(12))
True
```

The function does not accept negative arguments:

```
sage: q_bernoulli_polynomial(-1)
Traceback (most recent call last):
...
ValueError: the argument must be a nonnegative integer
```

REFERENCES: [Ca1948], [Ca1954]

```

Graph theory, posets, lattices (*Graph Theory*, *Posets*):

```
sage: Poset({1: [2,3], 2: [4], 3: [4]}).linear_extensions().cardinality()
2
```

5.1.163 Rankers

sage.combinat.ranker.**from_list**(*l*)

Returns a ranker from the list l.

INPUT:

- `l` - a list

OUTPUT:

- `[rank, unrank]` - functions

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: r,u = ranker.from_list(l)
sage: r(1)
0
sage: r(3)
2
sage: u(2)
3
sage: u(0)
1
```

sage.combinat.ranker.**on_fly**()

Returns a pair of enumeration functions rank / unrank.

rank assigns on the fly an integer, starting from 0, to any object passed as argument. The object should be hashable. unrank is the inverse function; it returns None for indices that have not yet been assigned.

EXAMPLES:

```
sage: [rank, unrank] = sage.combinat.ranker.on_fly()
sage: rank('a')
0
sage: rank('b')
1
```

```
sage: rank('c')
2
sage: rank('a')
0
sage: unrank(2)
'c'
sage: unrank(3)
sage: rank('d')
3
sage: unrank(3)
'd'
```

Todo

add tests as in combinat::rankers

---

sage.combinat.ranker.**rank_from_list**(*l*)

Return a rank function for the elements of `l`.

INPUT:

- `l` – a duplicate free list (or iterable) of hashable objects

OUTPUT:

- a function from the elements of `l` to `0,...,len(l)`

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = ['a', 'b', 'c']
sage: r = ranker.rank_from_list(l)
sage: r('a')
0
sage: r('c')
2
```

For non elements a `ValueError` is raised, as with the usual `index` method of lists:

```
sage: r('blah')
Traceback (most recent call last):
...
ValueError: 'blah' is not in dict
```

Currently, the rank function is a `CallableDict`; but this is an implementation detail:

```
sage: type(r)
<type 'sage.misc.callable_dict.CallableDict'>
sage: r
{'a': 0, 'c': 2, 'b': 1}
```

With the current implementation, no error is issued in case of duplicate value in `l`. Instead, the rank function returns the position of some of the duplicates:

```
sage: r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
sage: r('a')
2
```

Constructing the rank function itself is of complexity `O(len(l))`. Then, each call to the rank function consists of an essentially constant time dictionary lookup.

TESTS:

```
sage: TestSuite(r).run()
```

sage.combinat.ranker.**unrank**(*L*, *i*)

Return the i-th element of L.

INPUT:

- `L` – a list, tuple, finite enumerated set, ...
- `i` – an int or `Integer`

The purpose of this utility is to give a uniform idiom to recover the i-th element of an object `L`, whether `L` is a list, tuple (or more generally a `collections.Sequence`), an enumerated set, some old parent of Sage still implementing unranking in the method `__getitem__`, or an iterable (see `collections.Iterable`). See trac ticket #15919.

EXAMPLES:

Lists, tuples, and other `sequences`:

```
sage: from sage.combinat.ranker import unrank
sage: unrank(['a','b','c'], 2)
'c'
sage: unrank(('a','b','c'), 1)
'b'
sage: unrank(xrange(3,13,2), 1)
5
```

Enumerated sets:

```
sage: unrank(GF(7), 2)
2
sage: unrank(IntegerModRing(29), 10)
10
```

An old parent with unranking implemented in `__getitem__`:

```
sage: M = MatrixSpace(GF(3), 2, 2)
sage: hasattr(M, "unrank")
False
sage: M[42]
[1 0]
[2 1]
sage: unrank(M, 42)
[1 0]
[2 1]
```

An iterable:

```
sage: unrank(NN,4)
4
```

An iterator:

```
sage: unrank(('a{}'.format(i) for i in range(20)), 0)
'a0'
sage: unrank(('a{}'.format(i) for i in range(20)), 2)
'a2'
```

Warning: When unranking an iterator, it returns the `i`-th element beyond where it is currently at:

```
sage: from sage.combinat.ranker import unrank
sage: it = iter(range(20))
sage: unrank(it, 2)
2
sage: unrank(it, 2)
5
```

TESTS:

```
sage: from sage.combinat.ranker import unrank
sage: unrank(range(3), 10)
Traceback (most recent call last):
...
IndexError: list index out of range

sage: unrank(('a{}'.format(i) for i in range(20)), 22)
Traceback (most recent call last):
...
IndexError: index out of range

sage: M[100]
Traceback (most recent call last):
...
IndexError: list index out of range
```

sage.combinat.ranker.**unrank_from_list**(*l*)

Returns an unrank function from a list.

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: u = ranker.unrank_from_list(l)
sage: u(2)
3
sage: u(0)
1
```

5.1.164 Restricted growth arrays

class sage.combinat.restricted_growth.**RestrictedGrowthArrays**(*n*)

Bases: sage.combinat.combinat.CombinatorialClass

EXAMPLES:

```
sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(3)
sage: R == loads(dumps(R))
True
```

cardinality()

EXAMPLES:

```
sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(6)
```

```
sage: R.cardinality()
203
```

5.1.165 Ribbons

5.1.166 Ribbon Shaped Tableaux

class sage.combinat.ribbon_shaped_tableau.**RibbonShapedTableau**(*parent*, *t*)

Bases: sage.combinat.skew_tableau.SkewTableau

A ribbon shaped tableau.

For the purposes of this class, a ribbon shaped tableau is a skew tableau whose shape is a skew partition which:

- has at least one cell in row 1;
- has at least one cell in column 1;
- has exactly one cell in each of q consecutive diagonals, for some nonnegative integer q.

A ribbon is given by a list of the rows from top to bottom.

EXAMPLES:

```
sage: x = RibbonShapedTableau([[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]); x
[[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]
sage: x.pp()
  .  .  .  2  3
  .  1  4  5
  3  2
sage: x.shape()
[5, 4, 2] / [3, 1]
```

The entries labeled by `None` correspond to the inner partition. Using `None` is optional; the entries will be shifted accordingly.

```
sage: x = RibbonShapedTableau([[2,3],[1,4,5],[3,2]]); x.pp()
  .  .  .  2  3
  .  1  4  5
  3  2
```

TESTS:

```
sage: r = RibbonShapedTableau([[1], [2,3], [4, 5, 6]])
sage: r.to_permutation()
[4, 5, 6, 2, 3, 1]

sage: RibbonShapedTableau([[1,2],[3,4]]).evaluation()
[1, 1, 1, 1]
```

height()

Return the height of `self`.

The height is given by the number of rows in the outer partition.

EXAMPLES:

```
sage: RibbonShapedTableau([[2,3],[1,4,5]]).height()
2
```

spin()
Return the spin of `self`.

EXAMPLES:

```
sage: RibbonShapedTableau([[2,3],[1,4,5]]).spin()
1/2
```

width()
Return the width of the ribbon.

This is given by the length of the longest row in the outer partition.

EXAMPLES:

```
sage: RibbonShapedTableau([[2,3],[1,4,5]]).width()
4
sage: RibbonShapedTableau([]).width()
0
```

class sage.combinat.ribbon_shaped_tableau.**RibbonShapedTableaux**(*category=None*)
Bases: sage.combinat.skew_tableau.SkewTableaux

The set of all ribbon shaped tableaux.

Element
alias of RibbonShapedTableau

from_shape_and_word(*shape*, *word*)
Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

```
sage: RibbonShapedTableaux().from_shape_and_word([1,3],[1,3,3,7])
[[None, None, 1], [3, 3, 7]]
```

global_options(**get_value*, ***set_value*)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- `ascii_art` – (default: `repr`) Controls the ascii art output for tableaux
  - `compact` – minimal length ascii art
  - `repr` – display using the diagram string representation
  - `table` – display as a table
- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
  - `English` – use the English convention
  - `French` – use the French convention
- `display` – (default: `list`) Controls the way in which tableaux are printed
  - `array` – alias for `diagram`
  - `compact` – minimal length string representation
  - `diagram` – display as Young diagram (similar to `pp()`
  - `ferrers_diagram` – alias for `diagram`
  - `list` – print tableaux as lists

  - –young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed
  - –array – alias for diagram
  - –diagram – as a Young diagram
  - –ferrers_diagram – alias for diagram
  - –list – as a list
  - –young_diagram – alias for diagram
- notation – alternative name for convention

Note: Changing the convention for tableaux also changes the convention for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.global_options(display="array")
sage: T
  1  2  3
  4  5
sage: Tableaux.global_options(convention="french")
sage: T
  4  5
  1  2  3
```

Changing the convention for tableaux also changes the convention for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print P.ferrers_diagram()
*
***
***
sage: Partitions.global_options(convention="english")
sage: print P.ferrers_diagram()
***
***
*
sage: T
  1  2  3
  4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1  2  3
  4  5
sage: Tableaux.global_options(ascii_art="table")
sage: ascii_art(t)
+---+---+
| 4 | 5 |
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
```

```
sage: Tableaux.global_options(ascii_art="compact")
sage: ascii_art(t)
|4|5|
|1|2|3|
sage: Tableaux.global_options.reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.ribbon_shaped_tableau.**Ribbon_class**(*parent*, *t*)
Bases: sage.combinat.ribbon_shaped_tableau.RibbonShapedTableau

This exists solely for unpickling `Ribbon_class` objects.

class sage.combinat.ribbon_shaped_tableau.**StandardRibbonShapedTableaux**(*category=None*)
Bases: sage.combinat.skew_tableau.StandardSkewTableaux

The set of all standard ribbon shaped tableaux.

INPUT:

- `shape` – (optional) the composition shape of the rows

Element
alias of RibbonShapedTableau

from_permutation(*p*)
Return a standard ribbon of size `len(p)` from a permutation `p`. The lengths of each row are given by the distance between the descents of the permutation `p`.

EXAMPLES:

```
sage: import sage.combinat.ribbon_shaped_tableau as rst
sage: [StandardRibbonShapedTableaux().from_permutation(p) for p in Permutations(3)]
[[[1, 2, 3]],
 [[None, 2], [1, 3]],
 [[1, 3], [2]],
 [[None, 1], [2, 3]],
 [[1, 2], [3]],
 [[1], [2], [3]]]
```

from_shape_and_word(*shape*, *word*)
Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux().from_shape_and_word([2,3],[1,2,3,4,5])
[[None, None, 1, 2], [3, 4, 5]]
```

global_options(**get_value*, ***set_value*)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- `ascii_art` – (default: `repr`) Controls the ascii art output for tableaux
  - `compact` – minimal length ascii art
  - `repr` – display using the diagram string representation
  - `table` – display as a table
- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions

– `English` – use the English convention

– `French` – use the French convention

- `display` – (default: `list`) Controls the way in which tableaux are printed
  – `array` – alias for `diagram`
  – `compact` – minimal length string representation
  – `diagram` – display as Young diagram (similar to `pp()`
  – `ferrers_diagram` – alias for `diagram`
  – `list` – print tableaux as lists
  – `young_diagram` – alias for `diagram`
- `latex` – (default: `diagram`) Controls the way in which tableaux are latexed
  – `array` – alias for `diagram`
  – `diagram` – as a Young diagram
  – `ferrers_diagram` – alias for `diagram`
  – `list` – as a list
  – `young_diagram` – alias for `diagram`
- `notation` – alternative name for `convention`

Note: Changing the `convention` for tableaux also changes the `convention` for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.global_options(display="array")
sage: T
  1  2  3
  4  5
sage: Tableaux.global_options(convention="french")
sage: T
  4  5
  1  2  3
```

Changing the `convention` for tableaux also changes the `convention` for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print P.ferrers_diagram()
*
***
***
sage: Partitions.global_options(convention="english")
sage: print P.ferrers_diagram()
***
***
*
sage: T
  1  2  3
  4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1  2  3
  4  5
sage: Tableaux.global_options(ascii_art="table")
sage: ascii_art(t)
+---+---+
| 4 | 5 |
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
sage: Tableaux.global_options(ascii_art="compact")
sage: ascii_art(t)
|4|5|
|1|2|3|
sage: Tableaux.global_options.reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.ribbon_shaped_tableau.**StandardRibbonShapedTableaux_shape**(*shape*)

Bases: sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux

Class of standard ribbon shaped tableaux of ribbon shape `shape`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2,2])
Standard ribbon shaped tableaux of shape [2, 2]
sage: StandardRibbonShapedTableaux([2,2]).first()
[[None, 2, 4], [1, 3]]
sage: StandardRibbonShapedTableaux([2,2]).last()
[[None, 1, 2], [3, 4]]
sage: StandardRibbonShapedTableaux([2,2]).cardinality()
5
sage: StandardRibbonShapedTableaux([2,2]).list()
[[[None, 2, 4], [1, 3]],
 [[None, 2, 3], [1, 4]],
 [[None, 1, 4], [2, 3]],
 [[None, 1, 3], [2, 4]],
 [[None, 1, 2], [3, 4]]]
sage: StandardRibbonShapedTableaux([3,2,2]).cardinality()
155
```

first()

Return the first standard ribbon of `self`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2,2]).first()
[[None, 2, 4], [1, 3]]
```

last()

Return the last standard ribbon of `self`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2,2]).last()
[[None, 1, 2], [3, 4]]
```

5.1.167 Ribbon Tableaux

class sage.combinat.ribbon_tableau.**MultiSkewTableau**(*parent*, **args*, ***kwds*)
Bases: sage.combinat.combinat.CombinatorialElement

A multi skew tableau which is a tuple of skew tableaux.

EXAMPLES:

```
sage: s = MultiSkewTableau([ [[None,1],[2,3]], [[1,2],[2]] ])
sage: s.size()
6
sage: s.weight()
[2, 3, 1]
sage: s.shape()
[[2, 2] / [1], [2, 1] / []]
```

TESTS:

```
sage: mst = MultiSkewTableau([ [[None,1],[2,3]], [[1,2],[2]] ])
sage: TestSuite(mst).run()
```

inversion_pairs()
Return a list of the inversion pairs of self.

EXAMPLES:

```
sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])
sage: s.inversion_pairs()
[((0, (0, 0)), (1, (0, 0))),
 ((0, (1, 0)), (1, (0, 1))),
 ((0, (1, 1)), (1, (0, 0))),
 ((0, (1, 1)), (1, (1, 1))),
 ((0, (1, 1)), (2, (0, 0))),
 ((1, (0, 1)), (2, (0, 0))),
 ((1, (1, 1)), (2, (0, 0)))]
```

inversions()
Return the number of inversion pairs of self.

EXAMPLES:

```
sage: t1 = SkewTableau([[1]])
sage: t2 = SkewTableau([[2]])
sage: MultiSkewTableau([t1,t1]).inversions()
0
sage: MultiSkewTableau([t1,t2]).inversions()
0
sage: MultiSkewTableau([t2,t2]).inversions()
0
sage: MultiSkewTableau([t2,t1]).inversions()
1
sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])
sage: s.inversions()
7
```

shape()
Return the shape of self.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.shape()
[[2, 2] / [1], [2, 2] / [1], [2, 2] / [1]]
```

size()

Return the size of `self`, which is the sum of the sizes of the skew tableaux in `self`.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.size()
9
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.weight()
[5, 3, 1]
```

class sage.combinat.ribbon_tableau.**MultiSkewTableaux**(*category=None*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Multiskew tableaux.

Element

alias of MultiSkewTableau

class sage.combinat.ribbon_tableau.**RibbonTableau**(*parent*, *st*)

Bases: sage.combinat.skew_tableau.SkewTableau

A ribbon tableau.

A ribbon is a connected skew shape which does not contain any 2×2 boxes. A ribbon tableau is a skew tableau whose shape is partitioned into ribbons, each of which is filled with identical entries.

EXAMPLES:

```
sage: rt = RibbonTableau([[None, 1],[2,3]]); rt
[[None, 1], [2, 3]]
sage: rt.inner_shape()
[1]
sage: rt.outer_shape()
[2, 2]

sage: rt = RibbonTableau([[None, None, 0, 0, 0], [None, 0, 0, 2], [1, 0, 1]]); rt.pp()
  .  .  0  0  0
  .  0  0  2
  1  0  1
```

In the previous example, each ribbon is uniquely determined by a non-zero entry. The 0 entries are used to fill in the rest of the skew shape.

Note: Sanity checks are not performed; lists can contain any object.

```
sage: RibbonTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

TESTS:

```
sage: RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]]).evaluation()
[2, 1, 1, 1]
```

length()

Return the length of the ribbons into a ribbon tableau.

EXAMPLES:

```
sage: RibbonTableau([[None, 1],[2,3]]).length()
1
sage: RibbonTableau([[1,0],[2,0]]).length()
2
```

to_word()

Return a word obtained from a row reading of `self`.

Warning: Unlike the `to_word` method on skew tableaux (which are a superclass of this), this method does not filter out `None` entries.

EXAMPLES:

```
sage: R = RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]])
sage: R.to_word()
word: 2041100030
```

class sage.combinat.ribbon_tableau.**RibbonTableau_class**(*parent*, *st*)

Bases: sage.combinat.ribbon_tableau.RibbonTableau

This exists solely for unpickling `RibbonTableau_class` objects.

class sage.combinat.ribbon_tableau.**RibbonTableaux**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Ribbon tableaux.

A ribbon tableau is a skew tableau whose skew shape `shape` is tiled by ribbons of length `length`. The weight `weight` is calculated from the labels on the ribbons.

Note: Here we impose the condition that the ribbon tableaux are semistandard.

INPUT(Optional):

- `shape` – skew shape as a list of lists or an object of type SkewPartition
- `length` – integer, `shape` is partitioned into ribbons of length `length`
- `weight` – list of integers, computed from the values of non-zero entries labeling the ribbons

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]], [1,1,1], 1)
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons
```

```
sage: R = RibbonTableaux([[5,4,3],[2,1]], [2,1], 3)
sage: for i in R: i.pp(); print
```

```
.  .  0  0  0
.  0  0  2
1  0  1

.  .  1  0  0
.  0  0  0
1  0  2

.  .  0  0  0
.  1  0  1
2  0  0
```

REFRENCES:

Element
alias of RibbonTableau

from_expr(*l*)
Return a RibbonTableau from a MuPAD-Combinat expr for a skew tableau. The first list in expr is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: RibbonTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

global_options(**get_value*, ***set_value*)
Sets the global options for elements of the tableau, skew_tableau, and tableau tuple classes. The defaults are for tableau to be displayed as a list, latexed as a Young diagram using the English convention.

OPTIONS:

- ascii_art – (default: repr) Controls the ascii art output for tableaux
  - compact – minimal length ascii art
  - repr – display using the diagram string representation
  - table – display as a table
- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: list) Controls the way in which tableaux are printed
  - array – alias for diagram
  - compact – minimal length string representation
  - diagram – display as Young diagram (similar to pp())
  - ferrers_diagram – alias for diagram
  - list – print tableaux as lists
  - young_diagram – alias for diagram
- latex – (default: diagram) Controls the way in which tableaux are latexed

- `array` – alias for `diagram`
- `diagram` – as a Young diagram
- `ferrers_diagram` – alias for `diagram`
- `list` – as a list
- `young_diagram` – alias for `diagram`

• `notation` – alternative name for `convention`

Note: Changing the `convention` for tableaux also changes the `convention` for partitions.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T
[[1, 2, 3], [4, 5]]
sage: Tableaux.global_options(display="array")
sage: T
  1  2  3
  4  5
sage: Tableaux.global_options(convention="french")
sage: T
  4  5
  1  2  3
```

Changing the `convention` for tableaux also changes the `convention` for partitions and vice versa:

```
sage: P = Partition([3,3,1])
sage: print P.ferrers_diagram()
*
***
***
sage: Partitions.global_options(convention="english")
sage: print P.ferrers_diagram()
***
***
*
sage: T
  1  2  3
  4  5
```

The ASCII art can also be changed:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: ascii_art(t)
  1  2  3
  4  5
sage: Tableaux.global_options(ascii_art="table")
sage: ascii_art(t)
+---+---+
| 4 | 5 |
+---+---+---+
| 1 | 2 | 3 |
+---+---+---+
sage: Tableaux.global_options(ascii_art="compact")
sage: ascii_art(t)
|4|5|
```

```
|1|2|3|
sage: Tableaux.global_options.reset()
```

See `GlobalOptions` for more features of these options.

class sage.combinat.ribbon_tableau.**RibbonTableaux_shape_weight_length**(*shape*, *weight*, *length*)

Bases: sage.combinat.ribbon_tableau.RibbonTableaux

Ribbon tableaux of a given shape, weight, and length.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]],[1,1,1],1).cardinality()
2
sage: RibbonTableaux([[2,2],[]],[1,1],2).cardinality()
2
sage: RibbonTableaux([[4,3,3],[]],[2,1,1,1],2).cardinality()
5
```

TESTS:

```
sage: RibbonTableaux([6,6,6], [4,2], 3).cardinality()
6
sage: RibbonTableaux([3,3,3,2,1], [3,1], 3).cardinality()
1
sage: RibbonTableaux([3,3,3,2,1], [2,2], 3).cardinality()
2
sage: RibbonTableaux([3,3,3,2,1], [2,1,1], 3).cardinality()
5
sage: RibbonTableaux([3,3,3,2,1], [1,1,1,1], 3).cardinality()
12
sage: RibbonTableaux([5,4,3,2,1], [2,2,1], 3).cardinality()
10

sage: RibbonTableaux([8,7,6,5,1,1], [3,2,2,1], 3).cardinality()
85
sage: RibbonTableaux([5,4,3,2,1,1,1], [2,2,1], 3).cardinality()
10

sage: RibbonTableaux([7,7,7,2,1,1], [3,2,0,1,1], 3).cardinality()
25
```

Weights with some zeros in the middle and end:

```
sage: RibbonTableaux([3,3,3], [0,1,0,2,0], 3).cardinality()
3
sage: RibbonTableaux([3,3,3], [1,0,1,0,1,0,0,0], 3).cardinality()
6
```

class sage.combinat.ribbon_tableau.**SemistandardMultiSkewTableaux**(*shape*, *weight*)

Bases: sage.combinat.ribbon_tableau.MultiSkewTableaux

Semistandard multi skew tableaux.

A multi skew tableau is a k-tuple of skew tableaux of given shape with a specified total weight.

EXAMPLES:

```
sage: S = SemistandardMultiSkewTableaux([ [[2,1],[]], [[2,2],[1]] ], [2,2,2]); S
Semistandard multi skew tableaux of shape [[2, 1] / [], [2, 2] / [1]] and weight [2, 2, 2]
sage: S.list()
[[[[1, 1], [2]], [[None, 2], [3, 3]]],
 [[[1, 2], [2]], [[None, 1], [3, 3]]],
 [[[1, 3], [2]], [[None, 2], [1, 3]]],
 [[[1, 3], [2]], [[None, 1], [2, 3]]],
 [[[1, 1], [3]], [[None, 2], [2, 3]]],
 [[[1, 2], [3]], [[None, 2], [1, 3]]],
 [[[1, 2], [3]], [[None, 1], [2, 3]]],
 [[[2, 2], [3]], [[None, 1], [1, 3]]],
 [[[1, 3], [3]], [[None, 1], [2, 2]]],
 [[[2, 3], [3]], [[None, 1], [1, 2]]]]
```

sage.combinat.ribbon_tableau.**cospin_polynomial**(*part*, *weight*, *length*)

Return the cospin polynomial associated to `part`, `weight`, and `length`.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import cospin_polynomial
sage: cospin_polynomial([6,6,6],[4,2],3)
t^4 + t^3 + 2*t^2 + t + 1
sage: cospin_polynomial([3,3,3,2,1], [3,1], 3)
1
sage: cospin_polynomial([3,3,3,2,1], [2,2], 3)
t + 1
sage: cospin_polynomial([3,3,3,2,1], [2,1,1], 3)
t^2 + 2*t + 2
sage: cospin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
t^3 + 3*t^2 + 5*t + 3
sage: cospin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^2 + 6*t + 2
sage: cospin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3
```

sage.combinat.ribbon_tableau.**count_rec**(*nexts*, *current*, *part*, *weight*, *length*)

INPUT:

- `nexts, current, part` – skew partitions
- `weight` – non-negative integer list
- `length` – integer

TESTS:

```
sage: from sage.combinat.ribbon_tableau import count_rec
sage: count_rec([], [], [[2, 1, 1], []], [2], 2)
[0]
sage: count_rec([[0], [1]], [[[2, 1, 1], [0, 0, 2, 0]], [[4], [2, 0, 0, 0]]], [[4, 1, 1], []], [
[1]
sage: count_rec([], [[[], [2, 2]]], [[2, 2], []], [2], 2)
[1]
sage: count_rec([], [[[], [2, 0, 2, 0]]], [[4], []], [2], 2)
[1]
sage: count_rec([[1], [1]], [[[2, 2], [0, 0, 2, 0]], [[4], [2, 0, 0, 0]]], [[4, 2], []], [2, 1],
[2]
sage: count_rec([[1], [1], [2]], [[[2, 2, 2], [0, 0, 2, 0]], [[4, 1, 1], [0, 2, 0, 0]], [[4, 2],
[4]
sage: count_rec([[4], [1]], [[[4, 2, 2], [0, 0, 2, 0]], [[4, 3, 1], [0, 2, 0, 0]]], [[4, 3, 3],
[5]
```

sage.combinat.ribbon_tableau.**graph_implementation_rec**(*skp*, *weight*, *length*, *function*)

TESTS:

```
sage: from sage.combinat.ribbon_tableau import graph_implementation_rec, list_rec
sage: graph_implementation_rec(SkewPartition([[1], []]), [1], 1, list_rec)
[[[], [[1]]]]
sage: graph_implementation_rec(SkewPartition([[2, 1], []]), [1, 2], 1, list_rec)
[[[], [[2], [1, 2]]]]
sage: graph_implementation_rec(SkewPartition([[], []]), [0], 1, list_rec)
[[[], []]]
```

sage.combinat.ribbon_tableau.**insertion_tableau**(*skp*, *perm*, *evaluation*, *tableau*, *length*)

INPUT:

- `skp` – skew partitions
- `perm, evaluation` – non-negative integers
- `tableau` – skew tableau
- `length` – integer

TESTS:

```
sage: from sage.combinat.ribbon_tableau import insertion_tableau
sage: insertion_tableau([[1], []], [1], 1, [[], []], 1)
[[], [[1]]]
sage: insertion_tableau([[2, 1], []], [1, 1], 2, [[], [[1]]], 1)
[[], [[2], [1, 2]]]
sage: insertion_tableau([[2, 1], []], [0, 0], 3, [[], [[2], [1, 2]]], 1)

[[[], [[2, 2], [1, 1]]]]
```

sage.combinat.ribbon_tableau.**spin_polynomial**(*part*, *weight*, *length*)

Returns the spin polynomial associated to `part`, `weight`, and `length`.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial
sage: spin_polynomial([6,6,6],[4,2],3)
t^6 + t^5 + 2*t^4 + t^3 + t^2
sage: spin_polynomial([6,6,6],[4,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([3,3,3,2,1], [2,2], 3)
t^(7/2) + t^(5/2)
sage: spin_polynomial([3,3,3,2,1], [2,1,1], 3)
2*t^(7/2) + 2*t^(5/2) + t^(3/2)
sage: spin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
3*t^(7/2) + 5*t^(5/2) + 3*t^(3/2) + sqrt(t)
sage: spin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^(9/2) + 6*t^(7/2) + 2*t^(5/2)
sage: spin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

sage.combinat.ribbon_tableau.**spin_polynomial_square**(*part*, *weight*, *length*)

Returns the spin polynomial associated with `part`, `weight`, and `length`, with the substitution $t \to t^2$ made.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial_square
sage: spin_polynomial_square([6,6,6],[4,2],3)
t^12 + t^10 + 2*t^8 + t^6 + t^4
sage: spin_polynomial_square([6,6,6],[4,1,1],3)
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
sage: spin_polynomial_square([3,3,3,2,1], [2,2], 3)
t^7 + t^5
sage: spin_polynomial_square([3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
sage: spin_polynomial_square([3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + t
sage: spin_polynomial_square([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
```

```
sage: spin_polynomial_square([[6]*6, [3,3]], [4,4,2], 3)
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```

sage.combinat.ribbon_tableau.**spin_rec**(*t*, *nexts*, *current*, *part*, *weight*, *length*)

Routine used for constructing the spin polynomial.

INPUT:

- `weight` – list of non-negative integers
- `length` – the length of the ribbons we're tiling with
- `t` – the variable

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_rec
sage: sp = SkewPartition
sage: t = ZZ['t'].gen()
sage: spin_rec(t, [], [[[], [3, 3]]], sp([[2, 2, 2], []]), [2], 3)
[t^4]
sage: spin_rec(t, [[0], [t^4]], [[[2, 1, 1, 1, 1], [0, 3]], [[2, 2, 2], [3, 0]]], sp([[2, 2, 2,
[t^5]
sage: spin_rec(t, [], [[[], [3, 3, 0]]], sp([[3, 3], []]), [2], 3)
[t^2]
sage: spin_rec(t, [[t^4], [t^3], [t^2]], [[[2, 2, 2], [0, 0, 3]], [[3, 2, 1], [0, 3, 0]], [[3, 3
[t^6 + t^4 + t^2]
sage: spin_rec(t, [[t^5], [t^4], [t^6 + t^4 + t^2]], [[[2, 2, 2, 2, 1], [0, 0, 3]], [[3, 3, 1, 1
[2*t^7 + 2*t^5 + t^3]
```

5.1.169 Features that are imported by default in the interpreter namespace

5.1.170 Abstract classes for the rigged configuration bijections

This file contains two sets of classes, one for the bijection from KR tableaux to rigged configurations and the other for the reverse bijection. We do this for two reasons, one is because we can store a state in the bijection locally, so we do not have to constantly pass it around between functions. The other is because it makes the code easier to read in the *_element.py files.

These classes are not meant to be used by the user and are only supposed to be used internally to perform the bijections between `TensorProductOfKirillovReshetikhinTableaux` and `RiggedConfigurations`.

AUTHORS:

- Travis Scrimshaw (2011-04-15): Initial version

class `sage.combinat.rigged_configurations.bij_abstract_class.`**`KRTToRCBijectionAbstract`**(*tp_krt*)
Root abstract class for the bijection from KR tableaux to rigged configurations.

This class holds the state of the bijection and generates the next state. This class should never be created directly.

`next_state`(*val*)
Build the next state in the bijection.

INPUT:

- `val` – The value we are adding

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[5,3]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [3])
sage: bijection.next_state(3)
sage: bijection.ret_rig_con

-1[ ]-1

-1[ ]-1
```

```
(/)

(/)
```

run(*verbose=False*)

Run the bijection from a tensor product of KR tableaux to a rigged configuration.

INPUT:

- `tp_krt` – A tensor product of KR tableaux
- `verbose` – (Default: `False`) Display each step in the bijection

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: KRTToRCBijectionTypeA(KRT(pathlist=[[5,2]])).run()

-1[ ]-1

1[ ]1

0[ ]0

-1[ ]-1
```

class `sage.combinat.rigged_configurations.bij_abstract_class.`**RCToKRTBijectionAbstract**(*RC_eleme*

Root abstract class for the bijection from rigged configurations to tensor product of Kirillov-Reshetikhin tableaux.

This class holds the state of the bijection and generates the next state. This class should never be created directly.

next_state(*height*)

Build the next state in the bijection.

TESTS:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
sage: bijection = RCToKRTBijectionTypeA(RC(partition_list=[[1],[1],[1],[1]]))
sage: bijection.next_state(0)
5
sage: bijection.cur_partitions
[(/)
 , (/)
 , (/)
 , (/)
 ]
```

run(*verbose=False*, *build_graph=False*)

Run the bijection from rigged configurations to tensor product of KR tableaux.

INPUT:

- `verbose` – (default: `False`) display each step in the bijection
- `build_graph` – (default: `False`) build the graph of each step of the bijection

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1],[1],[1],[1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
sage: RCToKRTBijectionTypeA(x).run()
[[2], [5]]
sage: bij = RCToKRTBijectionTypeA(x)
sage: bij.run(build_graph=True)
[[2], [5]]
sage: bij._graph
Digraph on 3 vertices
```

5.1.171 Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux

AUTHORS:

- Travis Scrimshaw (2015-07-01): Initial version

REFERENCES:

class sage.combinat.rigged_configurations.bij_infinity.**FromRCIsomorphism**
Bases: sage.categories.morphism.Morphism

Crystal isomorphism of $B(\infty)$ in the rigged configuration model to the tableau model.

class sage.combinat.rigged_configurations.bij_infinity.**FromTableauIsomorphism**
Bases: sage.categories.morphism.Morphism

Crystal isomorphism of $B(\infty)$ in the tableau model to the rigged configuration model.

class sage.combinat.rigged_configurations.bij_infinity.**MLTToRCBijectionTypeB**(*tp_krt*)
Bases: sage.combinat.rigged_configurations.bij_type_B.KRTToRCBijectionTypeB

Initialize the bijection by obtaining the important information from the KR tableaux.

INPUT:

- `parent` – The parent of tensor product of KR tableaux

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[3,1]]))
sage: TestSuite(bijection).run()
```

run()
Run the bijection from a marginally large tableaux to a rigged configuration.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['B',4])
sage: T = crystals.infinity.Tableaux(['B',4])
sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_generators[0]})
sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
sage: all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest
True
```

class sage.combinat.rigged_configurations.bij_infinity.**MLTToRCBijectionTypeD**(*tp_krt*)
Bases: sage.combinat.rigged_configurations.bij_type_D.KRTToRCBijectionTypeD

Initialize the bijection by obtaining the important information from the KR tableaux.

INPUT:

- `parent` – The parent of tensor product of KR tableaux

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[3,1]]))
sage: TestSuite(bijection).run()
```

run()

Run the bijection from a marginally large tableaux to a rigged configuration.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
sage: T = crystals.infinity.Tableaux(['D',4])
sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_generators[0]})
sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
sage: all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest
True
```

class sage.combinat.rigged_configurations.bij_infinity.**RCToMLTBijectionTypeB**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_B.RCToKRTBijectionTypeB

Initialize the bijection helper.

INPUT:

- `RC_element` – The rigged configuration

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_abstract_class import RCToKRTBijectionAbstrac
sage: bijection = RCToKRTBijectionAbstract(RC(partition_list=[[1],[1],[1],[1]]))
sage: TestSuite(bijection).run()
```

run()

Run the bijection from rigged configurations to a marginally large tableau.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['B',4])
sage: T = crystals.infinity.Tableaux(['B',4])
sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
sage: all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
True
```

class sage.combinat.rigged_configurations.bij_infinity.**RCToMLTBijectionTypeD**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_D.RCToKRTBijectionTypeD

Initialize the bijection helper.

INPUT:

- `RC_element` – The rigged configuration

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_abstract_class import RCToKRTBijectionAbstrac
sage: bijection = RCToKRTBijectionAbstract(RC(partition_list=[[1],[1],[1],[1]]))
sage: TestSuite(bijection).run()
```

run()

Run the bijection from rigged configurations to a marginally large tableau.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
sage: T = crystals.infinity.Tableaux(['D',4])
sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
sage: all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
True
```

5.1.172 Bijection classes for type $A_n^{(1)}$

Part of the (internal) classes which run the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux of type $A_n^{(1)}$.

AUTHORS:

- Travis Scrimshaw (2011-04-15): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[5,2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
sage: bijection = RCToKRTBijectionTypeA(RC(partition_list=[[],[],[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_A.**KRTToRCBijectionTypeA**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_abstract_class.KRTToRCBijectionAbstract

Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_n^{(1)}$.

next_state(*val*)

Build the next state for type $A_n^{(1)}$.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA(KRT(pathlist=[[4,3]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [3])
sage: bijection.next_state(3)
```

class sage.combinat.rigged_configurations.bij_type_A.**RCToKRTBijectionTypeA**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_abstract_class.RCToKRTBijectionAbstract

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_n^{(1)}$.

next_state(*height*)

Build the next state for type $A_n^{(1)}$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
sage: bijection = RCToKRTBijectionTypeA(RC(partition_list=[[1],[1],[1],[1]]))
sage: bijection.next_state(0)
5
```

5.1.173 Bijection classes for type $A_{2n}^{(2)\dagger}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)\dagger}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(CartanType(['A', 4, 2]).dual(), [[2,
sage: from sage.combinat.rigged_configurations.bij_type_A2_dual import KRTToRCBijectionTypeA2Dual
sage: bijection = KRTToRCBijectionTypeA2Dual(KRT(pathlist=[[2,1]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_dual import RCToKRTBijectionTypeA2Dual
sage: bijection = RCToKRTBijectionTypeA2Dual(RC(partition_list=[[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_A2_dual.**KRTToRCBijectionTypeA2Dual**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC

Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)\dagger}$.

This inherits from type $C_n^{(1)}$ because we use the same methods in some places.

next_state(*val*)

Build the next state for type $A_{2n}^{(2)\dagger}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(CartanType(['A', 4, 2]).dual
sage: from sage.combinat.rigged_configurations.bij_type_A2_dual import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA2Dual(KRT(pathlist=[[-1,2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [2])
sage: bijection.next_state(2)
```

class sage.combinat.rigged_configurations.bij_type_A2_dual.**RCToKRTBijectionTypeA2Dual**(*RC_eleme*

Bases: sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)\dagger}$.

next_state(*height*)

Build the next state for type $A_{2n}^{(2)\dagger}$.

TESTS:

```
sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_dual import RCToKRTBijectionTypeA
sage: bijection = RCToKRTBijectionTypeA2Dual(RC(partition_list=[[2],[2,2]]))
sage: bijection.next_state(1)
-1
```

5.1.174 Bijection classes for type $A_{2n}^{(2)}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 2], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_even import KRTToRCBijectionTypeA2Even
sage: bijection = KRTToRCBijectionTypeA2Even(KRT(pathlist=[[-1,2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['A', 4, 2], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_even import RCToKRTBijectionTypeA2Even
sage: bijection = RCToKRTBijectionTypeA2Even(RC(partition_list=[[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_A2_even.**KRTToRCBijectionTypeA2Even**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC

Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)}$.

This inherits from type $C_n^{(1)}$ because we use the same methods in some places.

next_state(*val*)

Build the next state for type $A_{2n}^{(2)}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 2], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_even import KRTToRCBijectionTypeA
sage: bijection = KRTToRCBijectionTypeA2Even(KRT(pathlist=[[-1,-2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [-2])
sage: bijection.next_state(-2)
```

class sage.combinat.rigged_configurations.bij_type_A2_even.**RCToKRTBijectionTypeA2Even**(*RC_eleme*

Bases: sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)}$.

next_state(*height*)

Build the next state for type $A_{2n}^{(2)}$.

TESTS:

```
sage: RC = RiggedConfigurations(['A', 4, 2], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_even import RCToKRTBijectionTypeA
sage: bijection = RCToKRTBijectionTypeA2Even(RC(partition_list=[[2],[2,2]]))
sage: bijection.next_state(1)
-1
```

5.1.175 Bijection classes for type $A^{(2)}_{2n-1}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A^{(2)}_{2n-1}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 5, 2], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_odd import KRTToRCBijectionTypeA2Odd
sage: bijection = KRTToRCBijectionTypeA2Odd(KRT(pathlist=[[-1,2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['A', 5, 2], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_odd import RCToKRTBijectionTypeA2Odd
sage: bijection = RCToKRTBijectionTypeA2Odd(RC(partition_list=[[],[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_A2_odd.**KRTToRCBijectionTypeA2Odd**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA

Specific implementation of the bijection from KR tableaux to rigged configurations for type $A^{(2)}_{2n-1}$.

This inherits from type $A^{(1)}_n$ because we use the same methods in some places.

next_state(*val*)

Build the next state for type $A^{(2)}_{2n-1}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 5, 2], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_odd import KRTToRCBijectionTypeA2
sage: bijection = KRTToRCBijectionTypeA2Odd(KRT(pathlist=[[-2,3]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [3])
sage: bijection.next_state(3)
```

class sage.combinat.rigged_configurations.bij_type_A2_odd.**RCToKRTBijectionTypeA2Odd**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A^{(2)}_{2n-1}$.

next_state(*height*)

Build the next state for type $A^{(2)}_{2n-1}$.

TESTS:

```
sage: RC = RiggedConfigurations(['A', 5, 2], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_A2_odd import RCToKRTBijectionTypeA2
sage: bijection = RCToKRTBijectionTypeA2Odd(RC(partition_list=[[1],[2,1],[2]]))
```

```
sage: bijection.next_state(0)
-2
```

5.1.176 Bijection classes for type $B_n^{(1)}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $B_n^{(1)}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_B import KRTToRCBijectionTypeB
sage: bijection = KRTToRCBijectionTypeB(KRT(pathlist=[[-1,2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['B', 3, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_B import RCToKRTBijectionTypeB
sage: bijection = RCToKRTBijectionTypeB(RC(partition_list=[[],[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_B.**KRTToRCBijectionTypeB**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_C.KRTToRCBijectionTypeC

Specific implementation of the bijection from KR tableaux to rigged configurations for type $B_n^{(1)}$.

next_state(*val*)

Build the next state for type $B_n^{(1)}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_B import KRTToRCBijectionTypeB
sage: bijection = KRTToRCBijectionTypeB(KRT(pathlist=[[-1,2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [3])
sage: bijection.next_state(3)
```

other_outcome(*rc*, *pos_val*, *width_n*)

Do the other case (QS) possibility.

This arises from the ambiguity when we found a singular string at the max width in $\nu^{(n)}$. We had first attempted case (S), and if that resulted in an invalid rigged configuration, we now finish the bijection using case (QS).

EXAMPLES:

```
sage: RC = RiggedConfigurations(['B',3,1], [[2,1],[1,2]])
sage: rc = RC(partition_list=[[2,1], [2,1,1], [5,1]])
sage: t = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux()
sage: t.to_rigged_configuration() == rc # indirect doctest
True
```

run(*verbose=False*)

Run the bijection from a tensor product of KR tableaux to a rigged configuration.

INPUT:

- tp_krt – A tensor product of KR tableaux
- verbose – (Default: False) Display each step in the bijection

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.bij_type_B import KRTToRCBijectionTypeB
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1], [[2, 1]])
sage: KRTToRCBijectionTypeB(KRT(pathlist=[[0,3]])).run()

0[ ]0

-1[ ]-1
-1[ ]-1

0[]0

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1], [[3, 1]])
sage: KRTToRCBijectionTypeB(KRT(pathlist=[[-2,3,1]])).run()

(/)

-1[ ]-1

0[]0
```

TESTS:

Check that trac ticket #19384 is fixed:

```
sage: RC = RiggedConfigurations(['B',3,1], [[3,1],[3,1]])
sage: RC._test_bijection()
sage: RC = RiggedConfigurations(['B',3,1], [[1,1],[3,1],[1,1]])
sage: RC._test_bijection()
```

class sage.combinat.rigged_configurations.bij_type_B.**RCToKRTBijectionTypeB**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_C.RCToKRTBijectionTypeC

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $B_n^{(1)}$.

next_state(*height*)

Build the next state for type $B_n^{(1)}$.

TESTS:

```
sage: RC = RiggedConfigurations(['B', 3, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_B import RCToKRTBijectionTypeB
sage: bijection = RCToKRTBijectionTypeB(RC(partition_list=[[1],[1,1],[1]]))
sage: bijection.next_state(0)
0
```

run(*verbose=False*, *build_graph=False*)

Run the bijection from rigged configurations to tensor product of KR tableaux for type $B_n^{(1)}$.

INPUT:

- verbose – (default: False) display each step in the bijection
- build_graph – (default: False) build the graph of each step of the bijection

EXAMPLES:

```
sage: RC = RiggedConfigurations(['B', 3, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_B import RCToKRTBijectionTypeB
sage: RCToKRTBijectionTypeB(RC(partition_list=[[1],[1,1],[1]])).run()
[[3], [0]]

sage: RC = RiggedConfigurations(['B', 3, 1], [[3, 1]])
sage: x = RC(partition_list=[[],[1],[1]])
sage: RCToKRTBijectionTypeB(x).run()
[[1], [3], [-2]]
sage: bij = RCToKRTBijectionTypeB(x)
sage: bij.run(build_graph=True)
[[1], [3], [-2]]
sage: bij._graph
Digraph on 6 vertices
```

5.1.177 Bijection classes for type $C_n^{(1)}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $C_n^{(1)}$.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['C', 3, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_C import KRTToRCBijectionTypeC
sage: bijection = KRTToRCBijectionTypeC(KRT(pathlist=[[-1,2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['C', 3, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_C import RCToKRTBijectionTypeC
sage: bijection = RCToKRTBijectionTypeC(RC(partition_list=[[],[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_C.**KRTToRCBijectionTypeC**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA

Specific implementation of the bijection from KR tableaux to rigged configurations for type $C_n^{(1)}$.

This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

next_state(*val*)

Build the next state for type $C_n^{(1)}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['C', 3, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_C import KRTToRCBijectionTypeC
sage: bijection = KRTToRCBijectionTypeC(KRT(pathlist=[[-1,2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [2])
sage: bijection.next_state(2)
```

class sage.combinat.rigged_configurations.bij_type_C.**RCToKRTBijectionTypeC**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $C_n^{(1)}$.

next_state(*height*)

Build the next state for type $C_n^{(1)}$.

TESTS:

```
sage: RC = RiggedConfigurations(['C', 3, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_C import RCToKRTBijectionTypeC
sage: bijection = RCToKRTBijectionTypeC(RC(partition_list=[[2],[2],[1]]))
sage: bijection.next_state(0)
-1
```

5.1.178 Bijection classes for type $D_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_n^{(1)}$.

AUTHORS:

- Travis Scrimshaw (2011-04-15): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import KRTToRCBijectionTypeD
sage: bijection = KRTToRCBijectionTypeD(KRT(pathlist=[[3, 2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: bijection = RCToKRTBijectionTypeD(RC(partition_list=[[],[],[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_D.**KRTToRCBijectionTypeD**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA

Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_n^{(1)}$.

This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

doubling_map()

Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \hookrightarrow B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[4,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import KRTToRCBijectionTypeD
sage: bijection = KRTToRCBijectionTypeD(KRT(pathlist=[[-1,4,3,2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [2])
sage: bijection.next_state(2)
sage: bijection.ret_rig_con

-2[ ]-2

(/)

(/)
```

```
(/)

sage: bijection.cur_dims
[[0, 1]]
sage: bijection.doubling_map()
sage: bijection.ret_rig_con

-4[ ][ ]-4

(/)

(/)

(/)

sage: bijection.cur_dims
[[0, 2]]
```

halving_map()

Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \hookrightarrow B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[4,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import KRTToRCBijectionTypeD
sage: bijection = KRTToRCBijectionTypeD(KRT(pathlist=[[-1,4,3,2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [2])
sage: bijection.next_state(2)
sage: test = bijection.ret_rig_con
sage: bijection.doubling_map()
sage: bijection.halving_map()
sage: test == bijection.ret_rig_con
True
```

next_state(*val*)

Build the next state for type $D_n^{(1)}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import KRTToRCBijectionTypeD
sage: bijection = KRTToRCBijectionTypeD(KRT(pathlist=[[5,3]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [3])
sage: bijection.next_state(3)
```

run(*verbose=False*)

Run the bijection from a tensor product of KR tableaux to a rigged configuration for type $D_n^{(1)}$.

INPUT:

- `tp_krt` – A tensor product of KR tableaux
- `verbose` – (Default: `False`) Display each step in the bijection

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import KRTToRCBijectionTypeD
sage: KRTToRCBijectionTypeD(KRT(pathlist=[[-3,2]])).run()

-1[ ]-1

2[ ]2

-1[ ]-1

-1[ ]-1
```

class sage.combinat.rigged_configurations.bij_type_D.**RCToKRTBijectionTypeD**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D_n^{(1)}$.

doubling_map()

Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \hookrightarrow B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

TESTS:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[4, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: bijection = RCToKRTBijectionTypeD(RC(partition_list=[[],[],[],[1]]))

 ]
sage: bijection.doubling_map()
sage: bijection.cur_partitions
[(/)
 , (/)
 , (/)
 , -2[ ][ ]-2
 ]
```

halving_map()

Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \hookrightarrow B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

TESTS:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[4, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: bijection = RCToKRTBijectionTypeD(RC(partition_list=[[],[],[],[1]]))
sage: test = bijection.cur_partitions
sage: bijection.doubling_map()
sage: bijection.halving_map()
sage: test == bijection.cur_partitions
True
```

next_state(*height*)

Build the next state for type $D_n^{(1)}$.

TESTS:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: bijection = RCToKRTBijectionTypeD(RC(partition_list=[[],[1,1],[1],[1]]))
sage: bijection.next_state(0)
1
```

run(*verbose=False*, *build_graph=False*)

Run the bijection from rigged configurations to tensor product of KR tableaux for type $D_n^{(1)}$.

INPUT:

- `verbose` – (default: `False`) display each step in the bijection
- `build_graph` – (default: `False`) build the graph of each step of the bijection

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1],[1],[1],[1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import RCToKRTBijectionTypeD
sage: RCToKRTBijectionTypeD(x).run()
[[2], [-3]]
sage: bij = RCToKRTBijectionTypeD(x)
sage: bij.run(build_graph=True)
[[2], [-3]]
sage: bij._graph
Digraph on 3 vertices
```

5.1.179 Bijection classes for type $D_{n+1}^{(2)}$.

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_{n+1}^{(2)}$.

AUTHORS:

- Travis Scrimshaw (2011-04-15): Initial version

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 2], [[2,1]])

sage: bijection = KRTToRCBijectionTypeDTri(KRT(pathlist=[[-1,2]]))
sage: TestSuite(bijection).run()
sage: RC = RiggedConfigurations(['D', 4, 3], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D_tri import RCToKRTBijectionTypeDTri
sage: bijection = RCToKRTBijectionTypeDTri(RC(partition_list=[[],[]]))
sage: TestSuite(bijection).run()
```

class sage.combinat.rigged_configurations.bij_type_D_tri.**KRTToRCBijectionTypeDTri**(*tp_krt*)

Bases: sage.combinat.rigged_configurations.bij_type_A.KRTToRCBijectionTypeA

Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_4^{(3)}$.

This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

next_state(*val*)

Build the next state for type $D_4^{(3)}$.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 3], [[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D_tri import KRTToRCBijectionTypeDTr
sage: bijection = KRTToRCBijectionTypeDTri(KRT(pathlist=[[-1,2]]))
sage: bijection.cur_path.insert(0, [])
sage: bijection.cur_dims.insert(0, [0, 1])
sage: bijection.cur_path[0].insert(0, [2])
sage: bijection.next_state(2)
```

class sage.combinat.rigged_configurations.bij_type_D_tri.**RCToKRTBijectionTypeDTri**(*RC_element*)

Bases: sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D_4^{(3)}$.

next_state(*height*)

Build the next state for type $D_4^{(3)}$.

TESTS:

```
sage: RC = RiggedConfigurations(['D', 4, 3], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bij_type_D_tri import RCToKRTBijectionTypeDTr
sage: bijection = RCToKRTBijectionTypeDTri(RC(partition_list=[[3],[2]]))
sage: bijection.next_state(1)
-3
```

5.1.181 Bijection between rigged configurations and KR tableaux

Functions which are big switch statements to create the bijection class of the correct type.

AUTHORS:

- Travis Scrimshaw (2011-04-15): Initial version
- Travis Scrimshaw (2012-12-21): Added all non-exceptional bijection types
- Travis Scrimshaw (2014-09-10): Added type $D_4^{(3)}$

sage.combinat.rigged_configurations.bijection.**KRTToRCBijection**(*tp_krt*)
Return the correct KR tableaux to rigged configuration bijection helper class.

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1], [[2,1]])
sage: from sage.combinat.rigged_configurations.bijection import KRTToRCBijection
sage: bijection = KRTToRCBijection(KRT(pathlist=[[5,2]]))
```

sage.combinat.rigged_configurations.bijection.**RCToKRTBijection**(*rigged_configuration_elt*)
Return the correct rigged configuration to KR tableaux bijection helper class.

TESTS:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: from sage.combinat.rigged_configurations.bijection import RCToKRTBijection
sage: bijection = RCToKRTBijection(RC(partition_list=[[1],[1],[1],[1]]))
```

5.1.182 Kleber Trees

A Kleber tree is a tree of weights generated by Kleber's algorithm [Kleber1]. The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots of the difference.

AUTHORS:

- Travis Scrimshaw (2011-05-03): Initial version
- Travis Scrimshaw (2013-02-13): Added support for virtual trees and improved LaTeX output

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
Kleber tree of Cartan type ['A', 3, 1] and B = ((3, 2), (2, 1), (1, 1), (1, 1))
sage: KleberTree(['D', 4, 1], [[2,2]])
Kleber tree of Cartan type ['D', 4, 1] and B = ((2, 2),)
```

TESTS:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
sage: sorted((x.weight.to_vector(), x.up_root.to_vector()) for x in KT.list())
[((0, 0, 2), (1, 1, 0)),
 ((0, 0, 2), (2, 2, 1)),
 ((0, 1, 0), (0, 0, 1)),
 ((0, 1, 0), (1, 1, 1)),
 ((0, 2, 2), (1, 0, 0)),
 ((1, 0, 3), (1, 1, 0)),
 ((1, 1, 1), (1, 1, 1)),
 ((2, 0, 0), (0, 1, 1)),
 ((2, 1, 2), (0, 0, 0)),
 ((3, 0, 1), (0, 1, 1))]

sage: KT = KleberTree(['A', 7, 1], [[3,2], [2,1], [1,1]])
sage: KT
Kleber tree of Cartan type ['A', 7, 1] and B = ((3, 2), (2, 1), (1, 1))
sage: sorted((x.weight.to_vector(), x.up_root.to_vector()) for x in KT.list())
[((0, 0, 0, 1, 1, 0, 0), (1, 1, 1, 0, 0, 0, 0)),
 ((0, 0, 1, 0, 0, 1, 0), (2, 3, 3, 2, 1, 0, 0)),
 ((0, 0, 3, 0, 0, 0, 0), (1, 1, 0, 0, 0, 0, 0)),
 ((0, 1, 1, 1, 0, 0, 0), (1, 1, 1, 0, 0, 0, 0)),
 ((1, 0, 0, 2, 0, 0, 0), (0, 1, 1, 0, 0, 0, 0)),
 ((1, 0, 1, 0, 1, 0, 0), (1, 2, 2, 1, 0, 0, 0)),
 ((1, 1, 2, 0, 0, 0, 0), (0, 0, 0, 0, 0, 0, 0)),
 ((2, 0, 1, 1, 0, 0, 0), (0, 1, 1, 0, 0, 0, 0))]
```

class sage.combinat.rigged_configurations.kleber_tree.**KleberTree**(*cartan_type*, *B*, *classical_ct*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The tree that is generated by Kleber's algorithm.

A Kleber tree is a tree of weights generated by Kleber's algorithm [Kleber1]. It is used to generate the set of all admissible rigged configurations for the simply-laced affine types $A_n^{(1)}$, $D_n^{(1)}$, $E_6^{(1)}$, $E_7^{(1)}$, and $E_8^{(1)}$.

See also:

There is a modified version for non-simply-laced affine types at VirtualKleberTree.

The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots, and X is a child of Y if Y is the root else if the edge label of Y to its parent Z is greater (in every component) than the label from X to Y.

For a Kleber tree, one needs to specify an affine (simply-laced) Cartan type and a sequence of pairs (r, s), where s is any positive integer and r is a node in the Dynkin diagram. Each (r, s) can be viewed as a rectangle of width s and height r.

INPUT:

- cartan_type – an affine simply-laced Cartan type
- B – a list of dimensions of rectangles by $[r, c]$ where r is the number of rows and c is the number of columns

REFERENCES:

EXAMPLES:

Simply-laced example:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[3,2], [1,1]])
sage: KT.list()
[Kleber tree node with weight [1, 0, 2] and upwards edge root [0, 0, 0],
 Kleber tree node with weight [0, 0, 1] and upwards edge root [1, 1, 1]]
sage: KT = KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
sage: KT.cardinality()
10
sage: KT = KleberTree(['D', 4, 1], [[2,2]])
sage: KT.cardinality()
3
sage: KT = KleberTree(['D', 4, 1], [[4,5]])
sage: KT.cardinality()
1
```

From [Kleber2]:

```
sage: KT = KleberTree(['E', 6, 1], [[4, 2]])  # long time (9s on sage.math, 2012)
sage: KT.cardinality()  # long time
12
```

We check that relabelled types work (trac ticket #16876):

```
sage: ct = CartanType(['A',3,1]).relabel(lambda x: x+2)
sage: kt = KleberTree(ct, [[3,1],[5,1]])
sage: list(kt)
[Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
 Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 1, 1]]
sage: kt = KleberTree(['A',3,1], [[1,1],[3,1]])
sage: list(kt)
[Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
 Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 1, 1]]
```

Element
alias of KleberTreeNode

breadth_first_iter()
Iterate over all nodes in the tree following a breadth-first traversal.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

cartan_type()
Return the Cartan type of this Kleber tree.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[1,1]])
sage: KT.cartan_type()
['A', 3, 1]
```

depth_first_iter()

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

digraph()

Return a DiGraph representation of this Kleber tree.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
sage: KT.digraph()  # optional - dot2tex graphviz
Digraph on 3 vertices
```

latex_options(***options*)

Return the current latex options if no arguments are passed, otherwise set the corresponding latex option.

OPTIONS:

- `hspace` – (default: 2.5) the horizontal spacing of the tree nodes
- `vspace` – (default: `x`) the vertical spacing of the tree nodes, here `x` is the minimum of -2.5 or $-.75n$ where n is the rank of the classical type
- `edge_labels` – (default: `True`) display edge labels
- `use_vector_notation` – (default: `False`) display edge labels using vector notation instead of a linear combination

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 3, 1], [[2,1], [2,1]])
sage: KT.latex_options(vspace=-4, use_vector_notation=True)
sage: sorted(KT.latex_options().items())
[('edge_labels', True), ('hspace', 2.5), ('use_vector_notation', True), ('vspace', -4)]
```

plot(***options*)

Return the plot of self as a directed graph.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
sage: print(KT.plot())  # optional - dot2tex graphviz
Graphics object consisting of 8 graphics primitives
```

class sage.combinat.rigged_configurations.kleber_tree.**KleberTreeNode**(*parent_obj*, *node_weight*, *dominant_root*, *parent_node=None*)

Bases: sage.structure.element.Element

A node in the Kleber tree.

This class is meant to be used internally by the Kleber tree class and should not be created directly by the user.

For more on the Kleber tree and the nodes, see KleberTree.

The dominating root is the up_root which is the difference between the parent node's weight and this node's weight.

INPUT:

- parent_obj – The parent object of this element
- node_weight – The weight of this node
- dominant_root – The dominating root
- parent_node – (default:None) The parent node of this node

depth()

Return the depth of this node in the tree.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: RS = RootSystem(['A', 2])
sage: WS = RS.weight_space()
sage: R = RS.root_space()
sage: KT = KleberTree(['A', 2, 1], [[1,1]])
sage: n = KT(WS.sum_of_terms([(1,5), (2,2)]), R.zero())
sage: n.depth
0
sage: n2 = KT(WS.sum_of_terms([(1,5), (2,2)]), R.zero(), n)
sage: n2.depth
1
```

multiplicity()

Return the multiplicity of self.

The multiplicity of a node x of depth d weight λ in a simply-laced Kleber tree is equal to:

$$\prod_{i>0} \prod_{a \in \overline{I}} \binom{p_i^{(a)} + m_i^{(a)}}{p_i^{(a)}}$$

Recall that

$$m_i^{(a)} = \left(\lambda^{(i-1)} - 2\lambda^{(i)} + \lambda^{(i+1)} \mid \overline{\Lambda}_a \right),$$
$$p_i^{(a)} = \left(\alpha_a \mid \lambda^{(i)} \right) - \sum_{j>i} (j-i) L_j^{(a)},$$

where $\lambda^{(i)}$ is the weight node at depth i in the path to x from the root and we set $\lambda^{(j)} = \lambda$ for all $j \geq d$.

Note that $m_i^{(a)} = 0$ for all $i > d$.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A',3,1], [[3,2],[2,1],[1,1],[1,1]])
sage: for x in KT: x, x.multiplicity()
(Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 0, 0], 1)
(Kleber tree node with weight [0, 2, 2] and upwards edge root [1, 0, 0], 1)
(Kleber tree node with weight [1, 0, 3] and upwards edge root [1, 1, 0], 2)
(Kleber tree node with weight [1, 1, 1] and upwards edge root [1, 1, 1], 4)
(Kleber tree node with weight [0, 0, 2] and upwards edge root [2, 2, 1], 2)
(Kleber tree node with weight [3, 0, 1] and upwards edge root [0, 1, 1], 1)
(Kleber tree node with weight [2, 0, 0] and upwards edge root [0, 1, 1], 2)
(Kleber tree node with weight [0, 0, 2] and upwards edge root [1, 1, 0], 1)
(Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 1, 1], 2)
(Kleber tree node with weight [0, 1, 0] and upwards edge root [0, 0, 1], 1)
```

TESTS:

We check that trac ticket #16057 is fixed:

```
sage: RC = RiggedConfigurations(['D',4,1], [[1,3],[3,3],[4,3]])
sage: sum(x.multiplicity() for x in RC.kleber_tree()) == len(RC.module_generators)
True
```

class sage.combinat.rigged_configurations.kleber_tree.**KleberTreeTypeA2Even**(*cartan_type*, *B*)

Bases: sage.combinat.rigged_configurations.kleber_tree.VirtualKleberTree

Kleber tree for types $A_{2n}^{(2)}$ and $A_{2n}^{(2)\dagger}$.

Note that here for $A_{2n}^{(2)}$ we use $\tilde{\gamma}_a$ in place of γ_a in constructing the virtual Kleber tree, and so we end up selecting all nodes since $\tilde{\gamma}_a = 1$ for all $a \in \overline{I}$. For type $A_{2n}^{(2)\dagger}$, we have $\gamma_a = 1$ for all $a \in \overline{I}$.

See also:

VirtualKleberTree

breadth_first_iter(*all_nodes=False*)

Iterate over all nodes in the tree following a breadth-first traversal.

INPUT:

- `all_nodes` – (default: `False`) if `True`, output all nodes in the tree

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in KT.breadth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
```

depth_first_iter(*all_nodes=False*)

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

INPUT:

- `all_nodes` – (default: `False`) if `True`, output all nodes in the tree

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in KT.depth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
```

class sage.combinat.rigged_configurations.kleber_tree.**VirtualKleberTree**(*cartan_type*, *B*)

Bases: sage.combinat.rigged_configurations.kleber_tree.KleberTree

A virtual Kleber tree.

We can use a modified version of the Kleber algorithm called the virtual Kleber algorithm [OSS03] to compute all admissible rigged configurations for non-simply-laced types. This uses the following embeddings into the simply-laced types:

$$\begin{aligned} C_n^{(1)}, A_{2n}^{(2)}, A_{2n}^{(2)\dagger}, D_{n+1}^{(2)} &\hookrightarrow A_{2n-1}^{(1)} \\ A_{2n-1}^{(2)}, B_n^{(1)} &\hookrightarrow D_{n+1}^{(1)} \\ E_6^{(2)}, F_4^{(1)} &\hookrightarrow E_6^{(1)} \\ D_4^{(3)}, G_2^{(1)} &\hookrightarrow D_4^{(1)} \end{aligned}$$

One then selects the subset of admissible nodes which are translates of the virtual requirements. In the graph, the selected nodes are indicated by brackets [].

Note: Because these are virtual nodes, all information is given in the corresponding simply-laced type.

See also:

For more on the Kleber algorithm, see KleberTree.

REFERENCES:

INPUT:

- cartan_type – an affine non-simply-laced Cartan type
- B – a list of dimensions of rectangles by $[r, c]$ where r is the number of rows and c is the number of columns

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 4, 1], [[2,2]])
sage: KT.cardinality()
3
sage: KT.base_tree().cardinality()
6
sage: KT = VirtualKleberTree(['C', 4, 1], [[4,5]])
sage: KT.cardinality()
1
sage: KT = VirtualKleberTree(['D', 5, 2], [[2,1], [1,1]])
sage: KT.cardinality()
8
sage: KT = VirtualKleberTree(CartanType(['A', 4, 2]).dual(), [[1,1], [2,2]])
```

```
sage: KT.cardinality()
15
```

base_tree()

Return the underlying virtual Kleber tree associated to `self`.

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 4, 1], [[2,2]])
sage: KT.base_tree()
Kleber tree of Cartan type ['A', 7, 1] and B = ((2, 2), (6, 2))
```

breadth_first_iter(*all_nodes=False*)

Iterate over all nodes in the tree following a breadth-first traversal.

INPUT:

- `all_nodes` – (default: `False`) if `True`, output all nodes in the tree

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
sage: for x in KT.breadth_first_iter(True): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```

depth_first_iter(*all_nodes=False*)

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

INPUT:

- `all_nodes` – (default: `False`) if `True`, output all nodes in the tree

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
sage: for x in KT.depth_first_iter(True): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```

5.1.183 Kirillov-Reshetikhin Tableaux

Kirillov-Reshetikhin tableaux are rectangular tableaux with r rows and s columns that naturally arise under the bijection between rigged configurations and tableaux [RigConBijection]. They are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{r,s}$ under the (inverse) filling map [OSS13] [SchScr]. They do not have to satisfy the semistandard row or column restrictions. These tensor products are the result from the bijection from rigged configurations [RigConBijection].

For more information, see `KirillovReshetikhinTableaux` and `TensorProductOfKirillovReshetikhinTableaux`.

AUTHORS:

- Travis Scrimshaw (2012-01-03): Initial version
- Travis Scrimshaw (2012-11-14): Added bijection to KR crystals

REFERENCES:

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxBn**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeHorizonal

Kirillov-Reshetkhin tableaux $B^{n,s}$ of type $B_n^{(1)}$.

TESTS:

```
sage: KRT = crystals.KirillovReshetikhin(['B', 2, 1], 2, 3, model='KR')
sage: TestSuite(KRT).run()
```

Element

alias of KRTableauxSpinElement

from_kirillov_reshetikhin_crystal(*krc*)

Construct an element of `self` from the Kirillov-Reshetikhin crystal element `krc`.

EXAMPLES:

```
sage: KR = crystals.KirillovReshetikhin(['B',3,1], 3, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['B',3,1], 3, 3, model='KN')
sage: krc = C.module_generators[1].f_string([3,2,3,1,3,3]); krc

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxDTwistedSpin**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KRTableauxRectangle

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type $D_n^{(2)}$ with $r = n$.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 2], 1, 1, model='KR')
sage: KRT.cardinality()
8
sage: KRC = crystals.KirillovReshetikhin(['D', 4, 2], 1, 1, model='KN')
sage: KRT.cardinality() == KRC.cardinality()
True
```

Element

alias of KRTableauxSpinElement

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxRectangle**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux

Kirillov-Reshetkhin tableaux $B^{r,s}$ whose module generator is a single $r \times s$ rectangle.

These are Kirillov-Reshetkhin tableaux $B^{r,s}$ of type:

- $A_n^{(1)}$ for all $1 \leq r \leq n$,
- $C_n^{(1)}$ when $r = n$.

TESTS:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TestSuite(KRT).run()
sage: KRT = crystals.KirillovReshetikhin(['C', 3, 1], 3, 2, model='KR')
sage: TestSuite(KRT).run() # long time
```

from_kirillov_reshetikhin_crystal(*krc*)

Construct a KirillovReshetikhinTableauxElement.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: C = crystals.KirillovReshetikhin(['A',4,1], 2, 1, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3], [4]]
```

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxSpin**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KRTableauxRectangle

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type $D_n^{(1)}$ with $r = n, n-1$.

TESTS:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 3, 2, model='KR')
sage: TestSuite(KRT).run()
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 2, model='KR')
sage: TestSuite(KRT).run()
```

Element

alias of KRTableauxSpinElement

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxSpinElement**(*parent*, *list*, ***options*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement

Kirillov-Reshetikhin tableau for spinors.

Here we are in the embedding $B(\Lambda_n) \hookrightarrow B(2\Lambda_n)$, so e_i and f_i act by e_i^2 and f_i^2 respectively for all $i \neq 0$. We do this so our columns are full width (as opposed to half width and/or uses a $\pm$ representation).

e(*i*)

Calculate the action of e_i on self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).e(1)
[[1], [3], [-4], [-2]]
sage: KRT(-1, -4, 3, 2).e(3)
```

epsilon(*i*)

Compute ε_i of self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).epsilon(1)
1
```

```
sage: KRT(-1, -4, 3, 2).epsilon(3)
0
```

f(*i*)

Calculate the action of f_i on `self`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).f(1)
sage: KRT(-1, -4, 3, 2).f(3)
[[2], [4], [-3], [-1]]
```

left_split()

Return the image of `self` under the left column splitting map.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1); elt.pp()
  1  1  1
  2  2  3
 -4 -4 -4
 -3 -3 -2
sage: elt.left_split().pp()
  1 (X)    1  1
  2        2  3
 -4       -4 -4
 -3       -3 -2
```

phi(*i*)

Compute φ_i of `self`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).phi(1)
0
sage: KRT(-1, -4, 3, 2).phi(3)
1
```

to_array(*rows=True*)

Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is $[2, 1, 4, 3]$, so as a 2×2 tableau:

```
1 3
2 4
```

we output `[[1, 3], [2, 4]]`.

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be `[[2, 1], [4, 3]]`.

INPUT:

- `rows` – (Default: `True`) Set to `True` if the resulting array is by row, otherwise it is by column.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1)
sage: elt.to_array()
[[1, 1, 1], [2, 2, 3], [-4, -4, -4], [-3, -3, -2]]
sage: elt.to_array(False)
[[-3, -4, 2, 1], [-3, -4, 2, 1], [-2, -4, 3, 1]]
```

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxTypeBox**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeVertical

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type:

- $A_{2n}^{(2)}$ for all $r \leq n$,
- $D_{n+1}^{(2)}$ for all $r < n$,
- $D_4^{(3)}$ for $r = 1$.

TESTS:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KR')
sage: TestSuite(KRT).run()
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KR')
sage: TestSuite(KRT).run() # long time
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 3], 1, 2, model='KR')
sage: TestSuite(KRT).run() # long time
```

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxTypeDTri2**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux

Kirillov-Reshetikhin tableaux $B^{2,s}$ of type $D_4^{(3)}$.

Warning: The Kashiwara-Nakashima version is not implemented due to the non-trivial multiplicities of classical components, so `classical_decomposition()` does not work.

Element
alias of KRTableauxTypeDTri2Element

module_generators()
The module generators of `self`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators
([[1], [2]], [[1], [0]], [[1], [E]], [[E], [E]])
```

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxTypeDTri2Element**(*parent*, *list*, ***options*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement

A Kirillov-Reshetikhin tableau in $B^{2,s}$ of type $D_4^{(3)}$.

e(*i*)
Perform the action of e_i on `self`.

Todo

Implement a direct action of e_0 without moving to rigged configurations.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators[0].e(0)
[[2], [E]]
```

epsilon(*i*)

Compute ε_i of `self`.

Todo

Implement a direct action of ϵ_0 without moving to KR crystals.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
6
```

f(*i*)

Perform the action of f_i on `self`.

Todo

Implement a direct action of f_0 without moving to rigged configurations.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators[0].f(0)
sage: KRT.module_generators[3].f(0)
[[1], [0]]
```

phi(*i*)

Compute φ_i of `self`.

Todo

Compute ϕ_0 without moving to KR crystals.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 2, model='KR')
sage: KRT.module_generators[0].phi(0)
0
```

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxTypeHorizonal**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type:

- $C_n^{(1)}$ for $1 \leq r < n$,
- $A_{2n}^{(2)\dagger}$ for $1 \leq r \leq n$.

TESTS:

```
sage: KRT = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KR')
sage: TestSuite(KRT).run() # long time
sage: KRT = crystals.KirillovReshetikhin(CartanType(['A', 4, 2]).dual(), 2, 2, model='KR')
sage: TestSuite(KRT).run()
```

from_kirillov_reshetikhin_crystal(*krc*)

Construct an element of `self` from the Kirillov-Reshetikhin crystal element `krc`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3, -2, 1], [4, -1, 2]]
```

class sage.combinat.rigged_configurations.kr_tableaux.**KRTableauxTypeVertical**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableaux

Kirillov-Reshetkihn tableaux $B^{r,s}$ of type:

- $D_n^{(1)}$ for all $1 \leq r < n-1$,
- $B_n^{(1)}$ for all $1 \leq r < n$,
- $A_{2n-1}^{(2)}$ for all $1 \leq r \leq n$.

TESTS:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 1, 1, model='KR')
sage: TestSuite(KRT).run()
sage: KRT = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KR')
sage: TestSuite(KRT).run() # long time
sage: KRT = crystals.KirillovReshetikhin(['A', 5, 2], 2, 2, model='KR')
sage: TestSuite(KRT).run() # long time
```

from_kirillov_reshetikhin_crystal(*krc*)

Construct an element of `self` from the Kirillov-Reshetikhin crystal element `krc`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3, -2, 1], [4, -1, 2]]
```

class sage.combinat.rigged_configurations.kr_tableaux.**KirillovReshetikhinTableaux**(*cartan_type*, *r*, *s*)

Bases: sage.combinat.crystals.tensor_product.CrystalOfWords

Kirillov-Reshetikhin tableaux.

Kirillov-Reshetikhin tableaux are rectangular tableaux with r rows and s columns that naturally arise under the bijection between rigged configurations and tableaux [RigConBijection]. They are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{r,s}$ under the (inverse) filling map.

Whenever $B^{r,s} \cong B(s\Lambda_r)$ as a classical crystal (which is the case for $B^{r,s}$ in type $A_n^{(1)}$, $B^{n,s}$ in type $C_n^{(1)}$ and $D_{n+1}^{(2)}$, $B^{n,s}$ and $B^{n-1,s}$ in type $D_n^{(1)}$) then the filling map is trivial.

For $B^{r,s}$ in:

- type $D_n^{(1)}$ when $r \leq n-2$,
- type $B_n^{(1)}$ when $r < n$,
- type $A_{2n-1}^{(2)}$ for all r,

the filling map is defined in [OSS2011].

For the spinor cases in type $D_n^{(1)}$, the crystal $B^{k,s}$ where $k = n-1, n$, is isomorphic as a classical crystal to $B(s\Lambda_k)$, and here we consider the Kirillov-Reshetikhin tableaux as living in $B(2s\Lambda_k)$ under the natural doubling map. In this case, the crystal operators e_i and f_i act as e_i^2 and f_i^2 respectively. See [BijectionDn].

For the spinor case in type $B_n^{(1)}$, the crystal $B^{n,s}$, we consider the images under the natural doubling map into $B^{n,2s}$. The classical components of this crystal are now given by removing 2×2 boxes. The filling map is the same as below (see the non-spin type $C_n^{(1)}$).

For $B^{r,s}$ in:

- type $C_n^{(1)}$ when $r < n$,
- type $A_{2n}^{(2)\dagger}$ for all r,

the filling map is given as follows. Suppose we are considering the (classically) highest weight element in the classical component $B(\lambda)$. Then we fill it in with the horizontal dominoes $[\overline{\imath}, i]$ in the i-th row from the top (in English notation) and reordering the columns so that they are increasing. Recall from above that $B^{n,s} \cong B(s\Lambda_n)$ in type $C_n^{(1)}$.

For $B^{r,s}$ in:

- type $A_{2n}^{(2)}$ for all r,
- type $D_{n+1}^{(2)}$ when $r < n$,
- type $D_4^{(3)}$ when $r = 1$,

the filling map is the same as given in [OSS2011] except for the rightmost column which is given by the column $[1, 2, \ldots, k, \emptyset, \ldots \emptyset]$ where $k = (r + x - 1)/2$ in Step 3 of [OSS2011].

For the spinor case in type $D_{n+1}^{(2)}$, the crystal $B^{n,s}$, we define the filling map in the same way as in type $D_n^{(1)}$.

Note: The filling map and classical decompositions in non-spinor cases can be classified by how the special node 0 connects with the corresponding classical diagram.

The classical crystal stucture is given by the usual Kashiwara-Nakashima tableaux rules. That is to embed this into $B(\Lambda_1)^{\otimes ns}$ by using the reading word and then applying the classical crystal operator. The affine crystal stucture is given by converting to the corresponding KR crystal element, performing the affine crystal operator, and pulling back to a KR tableau.

For more information about the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux, see `TensorProductOfKirillovReshetikhinTableaux`.

Note: The tableaux for all non-simply-laced types are provably correct if the bijection with `rigged configurations` holds. Therefore this is currently only proven for $B^{r,1}$ or $B^{1,s}$ and in general for types $A_n^{(1)}$ and $D_n^{(1)}$.

INPUT:

- `cartan_type` – the Cartan type
- `r` – the Dynkin diagram index (typically the number of rows)
- `s` – the number of columns

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: elt = KRT(4, 3); elt
[[3], [4]]

sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1, model='KR')
sage: elt = KRT(-1, 1); elt
[[1], [-1]]
```

We can create highest weight crystals from a given shape or weight:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
sage: KRT.module_generator(column_shape=[2])
[[1, 1], [2, -1]]
sage: WS = RootSystem(['D',4,1]).weight_space()
sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]]))
[[1, 1], [2, -1]]
sage: WSC = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2))
[[1, 1], [2, -1]]
```

We can go between `KashiwaraNakashimaTableaux()` and `KirillovReshetikhinTableaux` elements:

```
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: elt = KRCrys(3, 2); elt
[[2], [3]]
sage: k = KRTab(elt); k
[[2, 1], [3, -1]]
sage: KRCrys(k)
[[2], [3]]
```

We check that the classical weights in the classical decompositions agree in a few different type:

```
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KRCrys = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KRCrys = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KR')
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
sage: KRCrys = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KR')
```

```
sage: all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)
True
```

Element
alias of KirillovReshetikhinTableauxElement

affinization()
Return the corresponding affinization crystal of self.

EXAMPLES:
```
sage: K = crystals.KirillovReshetikhin(['A',2,1], 1, 1, model='KR')
sage: K.affinization()
Affinization of Kirillov-Reshetikhin tableaux of type ['A', 2, 1] and shape (1, 1)
```

classical_decomposition()
Return the classical crystal decomposition of self.

EXAMPLES:
```
sage: crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR').classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]
```

from_kirillov_reshetikhin_crystal(*krc*)
Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

EXAMPLES:
```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: C = crystals.KirillovReshetikhin(['A',4,1], 2, 1, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3], [4]]
```

kirillov_reshetikhin_crystal()
Return the corresponding KR crystal in the Kashiwara-Nakashima model.

EXAMPLES:
```
sage: crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR').kirillov_reshetikhin_cryst
Kirillov-Reshetikhin crystal of type ['A', 4, 1] with (r,s)=(2,1)
```

module_generator(*i=None*, ***options*)
Return the specified module generator.

INPUT:

- i – the index of the module generator

We can also get a module generator by using one of the following optional arguments:

- shape – the associated shape
- column_shape – the shape given as columns (a column of length k correspond to a classical weight ω_k)
- weight – the weight
- classical_weight – the classical weight

If no arugments are specified, then return the unique module generator of classical weight $s\Lambda_r$.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(1)
[[1, 1], [2, -1]]
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
sage: KRT.module_generator(column_shape=[2])
[[1, 1], [2, -1]]
sage: WS = RootSystem(['D',4,1]).weight_space()
sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]]))
[[1, 1], [2, -1]]
sage: WSC = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2))
[[1, 1], [2, -1]]
sage: KRT.module_generator()
[[1, 1], [2, 2]]

sage: KRT = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: KRT.module_generator()
[[1, 1], [2, 2]]
```

r()

Return the value r for this tableaux class which corresponds to the number of rows.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: KRT.r()
2
```

s()

Return the value s for this tableaux class which corresponds to the number of columns.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: KRT.s()
1
```

tensor(**crystals*, ***options*)

Return the tensor product of `self` with `crystals`.

If `crystals` is a list of (a tensor product of) KR tableaux, this returns a `TensorProductOfKirillovReshetikhinTableaux`.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1,3],[3,1]])
sage: K.tensor(TP, K)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
 and factor(s) ((2, 2), (1, 3), (3, 1), (2, 2))

sage: C = crystals.KirillovReshetikhin(['A',3,1], 3, 1, model='KN')
sage: K.tensor(K, C)
Full tensor product of the crystals
 [Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
  Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
  Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]
```

class sage.combinat.rigged_configurations.kr_tableaux.**KirillovReshetikhinTableauxElement**(*parent*, *list*, ***options*)

Bases: sage.combinat.crystals.tensor_product.TensorProductOfRegularCrystalsElement

A Kirillov-Reshetikhin tableau.

For more information, see KirillovReshetikhinTableaux and TensorProductOfKirillovReshetikhinTableaux.

classical_weight()

Return the classical weight of self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)
```

e(i)

Perform the action of e_i on self.

Todo

Implement a direct action of e_0 without moving to KR crystals.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].e(0)
[[-2, 1], [-1, -1]]
```

epsilon(i)

Compute ε_i of self.

Todo

Implement a direct action of ε_0 without moving to KR crystals.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
2
```

f(i)

Perform the action of f_i on self.

Todo

Implement a direct action of f_0 without moving to KR crystals.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].f(0)
[[1, 1], [2, -1]]
```

left_split()
Return the image of `self` under the left column splitting map.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
  1 -2  1
  2 -1  2
sage: ls = mg.left_split(); ls.pp()
  1 (X)  -2  1
  2      -1  2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and factor(s) ((2, 1), (
```

lusztig_involution()
Return the result of the classical Lusztig involution on `self`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]
sage: mg.lusztig_involution()
[[-2, -2, 1], [-1, -1, 2]]
sage: elt = mg.f_string([2,1,3,2]); elt
[[3, -2, 1], [4, -1, 2]]
sage: elt.lusztig_involution()
[[-4, -2, 1], [-3, -1, 2]]
```

phi(i)
Compute φ_i of `self`.

Todo

Compute φ_0 without moving to KR crystals.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].phi(0)
2
```

pp()
Pretty print `self`.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3); elt
[[1, 3], [2, 4]]
sage: elt.pp()
1  3
2  4
```

right_split()
Return the image of `self` under the right column splitting map.

Let $*$ denote the `Lusztig involution`, and ls as the `left splitting map`. The right splitting map is defined as $\mathrm{rs} := * \circ \mathrm{ls} \circ *$.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
  1 -2  1
  2 -1  2
sage: ls = mg.right_split(); ls.pp()
 -2  1 (X)   1
 -1  2       2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and factor(s) ((2, 2), (
```

to_array(*rows=True*)

Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is $[2, 1, 4, 3]$, so as a 2×2 tableau:

```
1 3
2 4
```

we output `[[1, 3], [2, 4]]`.

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be `[[2, 1], [4, 3]]`.

INPUT:

- `rows` – (Default: `True`) Set to `True` if the resulting array is by row, otherwise it is by column.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3)
sage: elt.to_array()
[[1, 3], [2, 4]]
sage: elt.to_array(False)
[[2, 1], [4, 3]]
```

to_classical_highest_weight(*index_set=None*)

Return the classical highest weight element corresponding to `self`.

INPUT:

- `index_set` – (Default: `None`) Return the highest weight with respect to the index set. If `None` is passed in, then this uses the classical index set.

OUTPUT:

A pair `[H, f_str]` where `H` is the highest weight element and `f_str` is a list of a_i of f_{a_i} needed to reach `H`.

EXAMPLES:

```
sage: KRTab = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRTab(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_classical_highest_weight()
[[[1, 1], [2, -1]], [1, 2]]
```

to_kirillov_reshetikhin_crystal()

Construct a `KashiwaraNakashimaTableaux()` element from `self`.

We construct the Kirillov-Reshetikhin crystal element as follows:

1.Determine the shape λ of the KR crystal from the weight.

2.Determine a path $e_{i_1} e_{i_2} \cdots e_{i_k}$ to the highest weight.

3.Apply $f_{i_k} \cdots f_{i_2} f_{i_1}$ to a highest weight KR crystal of shape λ.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_kirillov_reshetikhin_crystal()
[[2], [3]]
```

TESTS:

Spinor tests:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 3, model='KR')
sage: KRC = crystals.KirillovReshetikhin(['D',4,1], 4, 3, model='KN')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1); elt
[[1, 1, 1], [2, 2, 3], [-4, -4, -4], [-3, -3, -2]]
sage: ret = elt.to_kirillov_reshetikhin_crystal(); ret
[++--, [[1], [3], [-4], [-3]]]
sage: test = KRT(ret); test
[[1, 1, 1], [2, 2, 3], [-4, -4, -4], [-3, -3, -2]]
sage: test == elt
True
```

to_tableau()

Return a Tableau object of self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3); elt
[[1, 3], [2, 4]]
sage: t = elt.to_tableau(); t
[[1, 3], [2, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: KR = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KR.module_generators[1].weight()
-2*Lambda[0] + Lambda[2]
```

5.1.184 Crystal of Rigged Configurations

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

We only consider the highest weight crystal structure, not the Kirillov-Reshetikhin structure, and we extend this to symmetrizable types.

class sage.combinat.rigged_configurations.rc_crystal.**CrystalOfNonSimplyLacedRC**(*vct*, *wt*, *WLR*)

Bases: sage.combinat.rigged_configurations.rc_crystal.CrystalOfRiggedConfigurations

Highest weight crystal of rigged configurations in non-simply-laced type.

Element
alias of RCHWNonSimplyLacedElement

from_virtual(*vrc*)
Convert vrc in the virtual crystal into a rigged configution of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration

EXAMPLES:

```
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[2])
sage: elt = RC(partition_list=[[0], [1], [1]])
sage: elt == RC.from_virtual(RC.to_virtual(elt))
True
```

to_virtual(*rc*)
Convert rc into a rigged configuration in the virtual crystal.

INPUT:

- rc – a rigged configuration element

EXAMPLES:

```
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[2])
sage: elt = RC(partition_list=[[], [1], [1]]); elt

(/)

0[ ]0

-1[ ]-1

sage: RC.to_virtual(elt)

(/)

0[ ]0

-2[ ][ ]-2

0[ ]0

(/)
```

virtual()
Return the corresponding virtual crystal.

EXAMPLES:

```
sage: La = RootSystem(['C', 2, 1]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[0])
```

```
sage: RC
Crystal of rigged configurations of type ['C', 2, 1] and weight Lambda[0]
sage: RC.virtual
Crystal of rigged configurations of type ['A', 3, 1] and weight 2*Lambda[0]
```

class sage.combinat.rigged_configurations.rc_crystal.**CrystalOfRiggedConfigurations**(*wt*, *WLR*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

A highest weight crystal of rigged configurations.

The crystal structure for finite simply-laced types is given in [CrysStructSchilling06]. These were then shown to be the crystal operators in all finite types in [SchScr] and all simply-laced and a large class of foldings of simply-laced types in [SalScr].

INPUT:

- cartan_type – (optional) a Cartan type
- wt – the highest weight vector in the weight lattice

EXAMPLES:

For simplicity, we display the rigged configurations horizontally:

```
sage: RiggedConfigurations.global_options(display='horizontal')
```

We start with a simply-laced finite type:

```
sage: La = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1] + La[2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2])
0[ ]0   0[ ]-1
sage: mg.f_string([1,2,2])
0[ ]0   -2[ ][ ]-2
sage: mg.f_string([1,2,2,2])
sage: mg.f_string([2,1,1,2])
-1[ ][ ]-1   -1[ ][ ]-1
sage: RC.cardinality()
8
sage: T = crystals.Tableaux(['A', 2], shape=[2,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```

We reset the global options:

```
sage: RiggedConfigurations.global_options.reset()
```

REFERENCES:

Element
alias of RCHighestWeightElement

global_options(**get_value*, ***set_value*)
Sets and displays the global options for rigged configurations. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method RiggedConfigurations.global_options of RiggedConfigurations.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: vertical) Specifies how rigged configurations should be printed
  - horizontal – displayed horizontally
  - vertical – displayed vertically
- element_ascii_art – (default: True) display using the repr option element_ascii_art
- half_width_boxes_type_b – (default: True) display the last rigged partition in affine type B as half width boxes
- notation – alternative name for convention

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[2,2],[1,1],[1,1]])
sage: elt = RC(partition_list=[[3,1], [3], [1]])
sage: elt

-3[ ][ ][ ]-3
-1[ ]-1

1[ ][ ][ ]1

-1[ ]-1

sage: RiggedConfigurations.global_options(display="horizontal", convention="french")
sage: elt
-1[ ]-1          1[ ][ ][ ]1    -1[ ]-1
-3[ ][ ][ ]-3
```

Changing the convention for rigged configurations also changes the convention option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: elt
-3[ ][ ][ ]-3    1[ ][ ][ ]1    -1[ ]-1
-1[ ]-1
sage: T.pp()
  1  2  3
  4  5
sage: RiggedConfigurations.global_options.reset()
```

See GlobalOptions for more features of these options.

weight_lattice_realization()

Return the weight lattice realization used to express the weights of elements in self.

EXAMPLES:

```
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[0])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

5.1.185 Rigged Configurations of $\mathcal{B}(\infty)$

AUTHORS:

- Travis Scrimshaw (2013-04-16): Initial version

class sage.combinat.rigged_configurations.rc_infinity.**InfinityCrystalOfNonSimplyLacedRC**(*vct*)
Bases: sage.combinat.rigged_configurations.rc_infinity.InfinityCrystalOfRiggedConfigurati

Rigged configurations for $\mathcal{B}(\infty)$ in non-simply-laced types.

class Element(*parent*, *rigged_partitions*=[ ], ***options*)
Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RCNonSimplyLa

A rigged configuration in $\mathcal{B}(\infty)$ in non-simply-laced types.

TESTS:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: elt = RC(partition_list=[[1],[1,1],[1]])
sage: TestSuite(elt).run()
```

weight()
Return the weight of self.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: elt = RC(partition_list=[[1],[1,1],[1]], rigging_list=[[0],[-1,-1],[0]])
sage: elt.weight()
(-1, -1, 0)

sage: RC = crystals.infinity.RiggedConfigurations(['F', 4, 1])
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,0,3,4,2,2]); ascii_art(elt)
-1[ ]-1  0[ ]1  -2[ ][ ]-2  0[ ]1  -1[ ]-1
sage: wt = elt.weight(); wt
-Lambda[0] + Lambda[1] - 2*Lambda[2] + 3*Lambda[3] - Lambda[4] - delta
sage: al = RC.weight_lattice_realization().simple_roots()
sage: wt == -(al[0] + al[1] + 2*al[2] + al[3] + al[4])
True
```

InfinityCrystalOfNonSimplyLacedRC.**from_virtual**(*vrc*)
Convert vrc in the virtual crystal into a rigged configution of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 2])
sage: elt = RC(partition_list=[[3],[2]], rigging_list=[[-2],[0]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret

-3[ ][ ][ ]-2

-1[ ][ ]0
```

```
sage: ret == elt
True
```

InfinityCrystalOfNonSimplyLacedRC.**to_virtual**(*rc*)

Convert `rc` into a rigged configuration in the virtual crystal.

INPUT:

- `rc` – a rigged configuration element

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 2])
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,2,2,1,1]); elt

-3[ ][ ][ ]-2

-1[ ][ ]0

sage: velt = RC.to_virtual(elt); velt

-3[ ][ ][ ]-2

-2[ ][ ][ ][ ]0

-3[ ][ ][ ]-2

sage: velt.parent()
The infinity crystal of rigged configurations of type ['A', 3]
```

InfinityCrystalOfNonSimplyLacedRC.**virtual**()

Return the corresponding virtual crystal.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: RC
The infinity crystal of rigged configurations of type ['C', 3]
sage: RC.virtual
The infinity crystal of rigged configurations of type ['A', 5]
```

class sage.combinat.rigged_configurations.rc_infinity.**InfinityCrystalOfRiggedConfigurations**(*c*

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Rigged configuration model for $\mathcal{B}(\infty)$.

The crystal is generated by the empty rigged configuration with the same crystal structure given by the `highest weight model` except we remove the condition that the resulting rigged configuration needs to be valid when applying f_a.

INPUT:

- `cartan_type` – a Cartan type

EXAMPLES:

For simplicity, we display all of the rigged configurations horizontally:

```
sage: RiggedConfigurations.global_options(display='horizontal')
```

We begin with a simply-laced finite type:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3]); RC
The infinity crystal of rigged configurations of type ['A', 3]

sage: RC.global_options(display='horizontal')

sage: mg = RC.highest_weight_vector(); mg
(/)  (/)  (/)
sage: elt = mg.f_string([2,1,3,2]); elt
0[ ]0   -2[ ]-1   0[ ]0
        -2[ ]-1
sage: elt.e(1)
sage: elt.e(3)
sage: mg.f_string([2,1,3,2]).e(2)
-1[ ]-1  0[ ]1  -1[ ]-1
sage: mg.f_string([2,3,2,1,3,2])
0[ ]0  -3[ ][ ]-1  -1[ ][ ]-1
       -2[ ]-1
```

Next we consider a non-simply-laced finite type:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([2,1,3,2])
0[ ]0   -2[ ]-1   0[ ]0
        -2[ ]-1
sage: mg.f_string([2,3,2,1,3,2])
-1[ ]-1  -2[ ][ ][ ]-1  -1[ ][ ]0
```

We can also construct $B(\infty)$ using rigged configurations in affine types:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([0,1,2,3,0,1,3])
-1[ ]0  -1[ ]-1  1[ ]1  -1[ ][ ]-1
-1[ ]0  -1[ ]-1

sage: RC = crystals.infinity.RiggedConfigurations(['C', 3, 1])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,3,0])
-2[ ][ ]-1  -1[ ]0  -1[ ]-1  -4[ ][ ][ ]-2
            -1[ ]0  -1[ ]-1

sage: RC = crystals.infinity.RiggedConfigurations(['A', 6, 2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,3,0])
0[ ]-1  0[ ]1  -1[ ]-1  -4[ ][ ][ ]-2
0[ ]-1  0[ ]1  -1[ ]-1
```

We reset the global options:

```
sage: RiggedConfigurations.global_options.reset()
```

class **Element** (*parent*, *rigged_partitions*=[ ], ***options*)

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigu

A rigged configuration in $\mathcal{B}(\infty)$ in simply-laced types.

TESTS:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
sage: elt = RC(partition_list=[[1,1]]*4, rigging_list=[[1,1], [0,0], [0,0], [-1,-1]])
sage: TestSuite(elt).run()
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
sage: elt = RC(partition_list=[[1,1]]*4, rigging_list=[[1,1], [0,0], [0,0], [-1,-1]])
sage: elt.weight()
-2*delta
```

InfinityCrystalOfRiggedConfigurations.**global_options**(**get_value*, ***set_value*)

Sets and displays the global options for rigged configurations. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method RiggedConfigurations.global_options of RiggedConfigurations.

OPTIONS:

- `convention` – (default: `English`) Sets the convention used for displaying tableaux and partitions
  - `English` – use the English convention
  - `French` – use the French convention
- `display` – (default: `vertical`) Specifies how rigged configurations should be printed
  - `horizontal` – displayed horizontally
  - `vertical` – displayed vertically
- `element_ascii_art` – (default: `True`) display using the repr option `element_ascii_art`
- `half_width_boxes_type_b` – (default: `True`) display the last rigged partition in affine type B as half width boxes
- `notation` – alternative name for `convention`

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[2,2],[1,1],[1,1]])
sage: elt = RC(partition_list=[[3,1], [3], [1]])
sage: elt

-3[ ][ ][ ]-3
-1[ ]-1

1[ ][ ][ ]1

-1[ ]-1

sage: RiggedConfigurations.global_options(display="horizontal", convention="french")
sage: elt
-1[ ]-1          1[ ][ ][ ]1    -1[ ]-1
-3[ ][ ][ ]-3
```

Changing the `convention` for rigged configurations also changes the `convention` option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: elt
-3[ ][ ][ ]-3   1[ ][ ][ ]1   -1[ ]-1
-1[ ]-1
sage: T.pp()
  1  2  3
  4  5
sage: RiggedConfigurations.global_options.reset()
```

See `GlobalOptions` for more features of these options.

`InfinityCrystalOfRiggedConfigurations.`**`weight_lattice_realization`**`()`

Return the weight lattice realization used to express the weights of elements in `self`.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 2, 1])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

5.1.186 Rigged Configuration Elements

A rigged configuration element is a sequence of `RiggedPartition` objects.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version
- Travis Scrimshaw (2012-10-25): Added virtual rigged confingurations

class `sage.combinat.rigged_configurations.rigged_configuration_element.`**`KRRCNonSimplyLacedElem`**

Bases: `sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigura`
`sage.combinat.rigged_configurations.rigged_configuration_element.RCNonSimplyLacedEleme`

$U'_q(\mathfrak{g})$ rigged configurations in non-simply-laced types.

TESTS:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt

0[ ][ ][ ]0

0[ ][ ]0
sage: TestSuite(elt).run()
```

`cc``()`

Compute the cocharge statistic.

Computes the cocharge statistic [OSS03] on this rigged configuration (ν, J) by computing the cocharge as a virtual rigged configuration $(\hat{\nu}, \hat{J})$ and then using the identity $cc(\hat{\nu}, \hat{J}) = \gamma_0 cc(\nu, J)$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1],[2,1],[1,1]]).cocharge()
1
```

cocharge()

Compute the cocharge statistic.

Computes the cocharge statistic [OSS03] on this rigged configuration (ν, J) by computing the cocharge as a virtual rigged configuration $(\hat{\nu}, \hat{J})$ and then using the identity $cc(\hat{\nu}, \hat{J}) = \gamma_0 cc(\nu, J)$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1],[2,1],[1,1]]).cocharge()
1
```

e(a)

Return the action of e_a on `self`.

This works by lifting into the virtual configuration, then applying

$$e_a^v = \prod_{j \in \iota(a)} \hat{e}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',6,2], [[1,1]]*7)
sage: elt = RC(partition_list=[[1]*5,[2,1,1],[3,2]])
sage: elt.e(3)

0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0

0[ ][ ]0
1[ ]1
1[ ]1

1[ ][ ]1
1[ ]0
```

f(a)

Return the action of f_a on `self`.

This works by lifting into the virtual configuration, then applying

$$f_a^v = \prod_{j \in \iota(a)} \hat{f}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',6,2], [[1,1]]*7)
sage: elt = RC(partition_list=[[1]*5,[2,1,1],[2,1]], rigging_list=[[0]*5,[0,1,1],[1,0]])
sage: elt.f(3)
```

```
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0

1[ ][ ]1
1[ ]1
1[ ]1

-1[ ][ ][ ]-1
 0[ ][ ]0
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**KRRCSimplyLacedElement**

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigura

$U'_q(\mathfrak{g})$ rigged configurations in simply-laced types.

TESTS:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2,1], [1,1]])
sage: elt = RC(partition_list=[[1], [1], []]); elt

0[ ]0

0[ ]0

(/)

sage: TestSuite(elt).run()
```

cc()

Compute the cocharge statistic of `self`.

Computes the cocharge statistic [CrysStructSchilling06] on this rigged configuration (ν, J). The cocharge statistic is defined as:

$$cc(\nu, J) = \frac{1}{2} \sum_{a,b \in I_0} \sum_{j,k>0} (\alpha_a \mid \alpha_b) \min(j,k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i>0} \left| J^{(a,i)} \right|.$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2,1], [1,1]])
sage: RC(partition_list=[[1], [1], []]).cocharge()
1
```

charge()

Compute the charge statistic of `self`.

Let B denote a set of rigged configurations. The *charge* c of a rigged configuration b is computed as

$$c(b) = \max(cc(b) \mid b \in B) - cc(b).$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2,1], [1,1]])
sage: RC(partition_list=[[],[],[]]).charge()
2
sage: RC(partition_list=[[1], [1], []]).charge()
1
```

cocharge()

Compute the cocharge statistic of `self`.

Computes the cocharge statistic [CrysStructSchilling06] on this rigged configuration (ν, J). The cocharge statistic is defined as:

$$cc(\nu, J) = \frac{1}{2} \sum_{a,b \in I_0} \sum_{j,k>0} (\alpha_a \mid \alpha_b) \min(j,k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i>0} \left| J^{(a,i)} \right|.$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2,1], [1,1]])
sage: RC(partition_list=[[1], [1], []]).cocharge()
1
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**KRRCTypeA2DualElement**

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.KRRCNonSimplyLace

$U_q'(\mathfrak{g})$ rigged configurations in type $A_{2n}^{(2)\dagger}$.

cc()

Compute the cocharge statistic.

Computes the cocharge statistic [RigConBijection] on this rigged configuration (ν, J). The cocharge statistic is computed as:

$$cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i>0} t_a^\vee m_i^{(a)} \left(\sum_{j>0} \min(i,j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} t_a^\vee \sum_{i>0} \left| J^{(a,i)} \right|.$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1],[2,2]])
sage: sc = RC.cartan_type().as_folding().scaling_factors()
sage: all(mg.cocharge() * sc[0] == mg.to_virtual_configuration().cocharge()
....:     for mg in RC.module_generators)
True
```

cocharge()

Compute the cocharge statistic.

Computes the cocharge statistic [RigConBijection] on this rigged configuration (ν, J). The cocharge statistic is computed as:

$$cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i>0} t_a^\vee m_i^{(a)} \left(\sum_{j>0} \min(i,j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} t_a^\vee \sum_{i>0} \left| J^{(a,i)} \right|.$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1],[2,2]])
sage: sc = RC.cartan_type().as_folding().scaling_factors()
sage: all(mg.cocharge() * sc[0] == mg.to_virtual_configuration().cocharge()
....:     for mg in RC.module_generators)
True
```

epsilon(a)

Return the value of ε_a of `self`.

Here we need to modify the usual definition by $\varepsilon'_n := 2\varepsilon_n$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: def epsilon(x, i):
....:     x = x.e(i)
....:     eps = 0
....:     while x is not None:
....:         x = x.e(i)
....:         eps = eps + 1
....:     return eps
sage: all(epsilon(rc, 2) == rc.epsilon(2) for rc in RC)
True
```

phi(a)

Return the value of φ_a of `self`.

Here we need to modify the usual definition by $\varphi'_n := 2\varphi_n$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: def phi(x, i):
....:     x = x.f(i)
....:     ph = 0
....:     while x is not None:
....:         x = x.f(i)
....:         ph = ph + 1
....:     return ph
sage: all(phi(rc, 2) == rc.phi(2) for rc in RC)
True
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**KRRiggedConfigurationE**

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurati

$U'_q(\mathfrak{g})$ rigged configurations.

EXAMPLES:

We can go between rigged configurations and tensor products of tensor products of KR tableaux:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[1,1], [2,1]])
sage: rc_elt = RC(partition_list=[[1], [1,1], [1], [1]])
sage: tp_krtab = rc_elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krtab
[[-2]] (X) [[1], [2]]
sage: tp_krcrys = rc_elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krcrys
[[[-2]], [[1], [2]]]
```

```
sage: tp_krcrys == tp_krtab.to_tensor_product_of_kirillov_reshetikhin_crystals()
True
sage: RC(tp_krcrys) == rc_elt
True
sage: RC(tp_krtab) == rc_elt
True
sage: tp_krtab.to_rigged_configuration() == rc_elt
True
```

check()

Make sure all of the riggings are less than or equal to the vacancy number.

TESTS:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1], [1], [], []])
sage: elt.check()
```

classical_weight()

Return the classical weight of `self`.

The classical weight Λ of a rigged configuration is

$$\Lambda = \sum_{a \in \overline{I}} \sum_{i>0} iL_i^{(a)} \Lambda_a - \sum_{a \in \overline{I}} \sum_{i>0} im_i^{(a)} \alpha_a.$$

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D',4,1], [[2,2]])
sage: elt = RC(partition_list=[[2],[2,1],[1],[1]])
sage: elt.classical_weight()
(0, 1, 1, 0)
```

This agrees with the corresponding classical weight as KR tableaux:

```
sage: krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); krt
[[2, 1], [3, -1]]
sage: krt.classical_weight() == elt.classical_weight()
True
```

TESTS:

We check the classical weights agree in an entire crystal:

```
sage: RC = RiggedConfigurations(['A',2,1], [[2,1], [1,1]])
sage: for x in RC:
....:     y = x.to_tensor_product_of_kirillov_reshetikhin_tableaux()
....:     assert x.classical_weight() == y.classical_weight()
```

complement_rigging(*reverse_factors=False*)

Apply the complement rigging morphism θ to `self`.

Consider a highest weight rigged configuration (ν, J), the complement rigging morphism $\theta : RC(L) \to RC(L)$ is given by sending $(\nu, J) \mapsto (\nu, J')$, where J' is obtained by taking the coriggings $x' = p_i^{(a)} - x$, and then extending as a crystal morphism. (The name comes from taking the complement partition for the riggings in a $m_i^{(a)} \times p_i^{(a)}$ box.)

INPUT:

- `reverse_factors` – (default: `False`) if `True`, then this returns an element in $RC(B')$ where B' is the tensor factors of `self` in reverse order

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D',4,1], [[1,1],[2,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
1[ ][ ]1  0[ ][ ]0  0[ ][ ]0  0[ ][ ]0
          0[ ][ ]0
sage: ascii_art(mg.complement_rigging())
1[ ][ ]0  0[ ][ ]0  0[ ][ ]0  0[ ][ ]0
          0[ ][ ]0

sage: lw = mg.to_lowest_weight([1,2,3,4])[0]
sage: ascii_art(lw)
-1[ ][ ]-1  0[ ][ ]0  0[ ][ ]0  0[ ][ ]0
-1[ ]-1     0[ ][ ]0  0[ ]0     0[ ]0
-1[ ]-1     0[ ]0
            0[ ]0
sage: ascii_art(lw.complement_rigging())
-1[ ][ ][ ]-1  0[ ][ ][ ]0  0[ ][ ][ ]0  0[ ][ ][ ]0
-1[ ]-1        0[ ][ ][ ]0
sage: lw.complement_rigging() == mg.complement_rigging().to_lowest_weight([1,2,3,4])[0]
True

sage: mg.complement_rigging(True).parent()
Rigged configurations of type ['D', 4, 1] and factor(s) ((2, 2), (1, 1))
```

We check that the Lusztig involution (under the modification of also mapping to the highest weight element) intertwines with the complement map θ (that reverses the tensor factors) under the bijection Φ:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2], [2, 1], [1, 2]])
sage: for mg in RC.module_generators: # long time
....:     y = mg.to_tensor_product_of_kirillov_reshetikhin_tableaux()
....:     hw = y.lusztig_involution().to_highest_weight([1,2,3,4])[0]
....:     c = mg.complement_rigging(True)
....:     hwc = c.to_tensor_product_of_kirillov_reshetikhin_tableaux()
....:     assert hw == hwc
```

TESTS:

We check that trac ticket #18898 is fixed:

```
sage: RC = RiggedConfigurations(['D',4,1], [[2,1], [2,1], [2,3]])
sage: x = RC(partition_list=[[1], [1,1], [1], [1]], rigging_list=[[0], [2,1], [0], [0]])
sage: ascii_art(x)
0[ ]0  2[ ]2  0[ ]0  0[ ]0
       2[ ]1
sage: ascii_art(x.complement_rigging())
0[ ]0  2[ ]1  0[ ]0  0[ ]0
       2[ ]0
```

delta(*return_b=False*)

Return the image of `self` under the left box removal map δ.

The map $\delta : RC(B^{r,1} \otimes B) \to RC(B^{r-1,1} \otimes B)$ (if $r = 1$, then we remove the left-most factor) is the basic map in the bijection Φ between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see `to_tensor_product_of_kirillov_reshetikhin_tableaux()`. We can extend δ when the left-most factor is not a single column by precomposing with a `left_split()`.

Note: Due to the special nature of the bijection for the spinor cases in types $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$, this

map is not defined in these cases.

INPUT:

- `return_b` – (default: `False`) whether to return the resulting letter from δ

OUTPUT:

The resulting rigged configuration or if `return_b` is `True`, then a tuple of the resulting rigged configuration and the letter.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0  0[ ][ ]0  0[ ][ ]0  0[ ]0
          0[ ][ ]0  0[ ][ ]0  0[ ]0
                    0[ ][ ]0  0[ ]0
sage: ascii_art(mg.left_box())
0[ ]0  0[ ][ ]0  0[ ][ ]0  0[ ]0
       0[ ]0     0[ ][ ]0  0[ ]0
sage: x,b = mg.left_box(True)
sage: b
-1
sage: b.parent()
The crystal of letters for type ['C', 4]
```

e(a)

Return the action of the crystal operator e_a on `self`.

For the classical operators, this implements the method defined in [CrysStructSchilling06]. For e_0, this converts the class to a tensor product of KR tableaux and does the corresponding e_0 and pulls back.

Todo

Implement e_0 without appealing to tensor product of KR tableaux.

INPUT:

- `a` – the index of the partition to remove a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
sage: elt.e(1)

(/)

0[ ]0

0[ ]0

-1[ ]-1
```

epsilon(*a*)

Return ε_a of `self`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.epsilon(i) for i in I] for mg in RC.module_generators])
[4 0 0 0 0]
[3 0 0 0 0]
[2 0 0 0 0]
```

f(*a*)

Return the action of the crystal operator f_a on `self`.

For the classical operators, this implements the method defined in [CrysStructSchilling06]. For f_0, this converts the class to a tensor product of KR tableaux and does the corresponding f_0 and pulls back.

Todo

Implement f_0 without appealing to tensor product of KR tableaux.

INPUT:

- `a` – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.f(1)
sage: elt.f(2)

0[ ]0

-1[ ]-1
-1[ ]-1

1[ ]1

-1[ ]-1
```

left_box(*return_b=False*)

Return the image of `self` under the left box removal map δ.

The map $\delta : RC(B^{r,1} \otimes B) \to RC(B^{r-1,1} \otimes B)$ (if $r = 1$, then we remove the left-most factor) is the basic map in the bijection Φ between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see `to_tensor_product_of_kirillov_reshetikhin_tableaux()`. We can extend δ when the left-most factor is not a single column by precomposing with a `left_split()`.

Note: Due to the special nature of the bijection for the spinor cases in types $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$, this map is not defined in these cases.

INPUT:

- `return_b` – (default: `False`) whether to return the resulting letter from δ

OUTPUT:

The resulting rigged configuration or if `return_b` is `True`, then a tuple of the resulting rigged configuration and the letter.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0  0[ ][ ]0  0[ ][ ]0  0[ ]0
          0[ ][ ]0  0[ ][ ]0  0[ ]0
                    0[ ][ ]0  0[ ]0
sage: ascii_art(mg.left_box())
0[ ]0  0[ ][ ]0  0[ ][ ]0  0[ ]0
       0[ ]0     0[ ][ ]0  0[ ]0
sage: x,b = mg.left_box(True)
sage: b
-1
sage: b.parent()
The crystal of letters for type ['C', 4]
```

left_column_box()

Return the image of `self` under the left column box splitting map γ.

Consider the map $\gamma : RC(B^{r,1} \otimes B) \to RC(B^{1,1} \otimes B^{r-1,1} \otimes B)$ for $r > 1$, which is a natural strict classical crystal injection. On rigged configurations, the map γ adds a singular string of length 1 to $\nu^{(a)}$.

We can extend γ when the left-most factor is not a single column by precomposing with a `left_split()`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',3,1], [[3,1], [2,1]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ]0  0[ ][ ]0  0[ ]0
       0[ ]0     0[ ]0
sage: ascii_art(mg.left_column_box())
0[ ]0  0[ ][ ]0  0[ ]0
0[ ]0  0[ ]0     0[ ]0
       0[ ]0

sage: RC = RiggedConfigurations(['C',3,1], [[2,1], [1,1], [3,1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
1[ ]0  0[ ][ ]0  0[ ]0
       0[ ]0     0[ ]0
sage: ascii_art(mg.left_column_box())
1[ ]1  0[ ][ ]0  0[ ]0
1[ ]0  0[ ]0     0[ ]0
```

left_split()

Return the image of `self` under the left column splitting map β.

Consider the map $\beta : RC(B^{r,s} \otimes B) \to RC(B^{r,1} \otimes B^{r,s-1} \otimes B)$ for $s > 1$ which is a natural classical crystal injection. On rigged configurations, the map β does nothing (except possibly changing the vacancy numbers).

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0  0[ ][ ]0  0[ ][ ]0  0[ ]0
          0[ ][ ]0  0[ ][ ]0  0[ ]0
                    0[ ][ ]0  0[ ]0
sage: ascii_art(mg.left_split())
0[ ][ ]0  0[ ][ ]0  1[ ][ ]0  0[ ]0
          0[ ][ ]0  1[ ][ ]0  0[ ]0
                    1[ ][ ]0  0[ ]0
```

phi(a)

Return φ_a of `self`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.phi(i) for i in I] for mg in RC.module_generators])
[0 0 2 0 0]
[1 0 1 0 0]
[2 0 0 0 0]
```

right_column_box()

Return the image of `self` under the right column box splitting map γ^*.

Consider the map $\gamma^* : RC(B \otimes B^{r,1}) \to RC(B \otimes B^{r-1,1} \otimes B^{1,1})$ for $r > 1$, which is a natural strict classical crystal injection. On rigged configurations, the map γ adds a string of length 1 with rigging 0 to $\nu^{(a)}$ for all $a < r$ to a classically highest weight element and extended as a classical crystal morphism.

We can extend γ^* when the right-most factor is not a single column by precomposing with a `right_split()`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',3,1], [[2,1], [1,1], [3,1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
1[ ]0  0[ ][ ]0  0[ ]0
       0[ ]0     0[ ]0
sage: ascii_art(mg.right_column_box())
1[ ]0  0[ ][ ]0  0[ ]0
1[ ]0  0[ ]0     0[ ]0
       0[ ]0
```

right_split()

Return the image of `self` under the right column splitting map β^*.

Let θ denote the `complement rigging map` which reverses the tensor factors and β denote the `left splitting map`, we define the right splitting map by $\beta^* := \theta \circ \beta \circ \theta$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0  0[ ][ ]0  0[ ][ ]0  0[ ]0
          0[ ][ ]0  0[ ][ ]0  0[ ]0
                    0[ ][ ]0  0[ ]0
sage: ascii_art(mg.right_split())
0[ ][ ]0  0[ ][ ]0  1[ ][ ]1  0[ ]0
```

```
          0[ ][ ]0  1[ ][ ]1  0[ ]0
                    1[ ][ ]1  0[ ]0

sage: RC = RiggedConfigurations(['D',4,1], [[2,2],[1,2]])
sage: elt = RC(partition_list=[[3,1], [2,2,1], [2,1], [2]])
sage: ascii_art(elt)
-1[ ][ ][ ]-1  0[ ][ ]0  -1[ ][ ]-1  1[ ][ ]1
 0[ ]0         0[ ][ ]0  -1[ ]-1
               0[ ]0
sage: ascii_art(elt.right_split())
-1[ ][ ][ ]-1  0[ ][ ]0  -1[ ][ ]-1  1[ ][ ]1
 1[ ]0         0[ ][ ]0  -1[ ]-1
               0[ ]0
```

We check that the bijection commutes with the right spliting map:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[1,1], [2,2]])
sage: all(rc.right_split().to_tensor_product_of_kirillov_reshetikhin_tableaux()
....:     == rc.to_tensor_product_of_kirillov_reshetikhin_tableaux().right_split() for rc in
True
```

to_tensor_product_of_kirillov_reshetikhin_crystals(*display_steps=False*, *build_graph=False*)

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

This is a composition of the map to a tensor product of KR tableaux, and then to a tensor product of KR crystals.

INPUT:

- `display_steps` – (default: `False`) boolean which indicates if we want to print each step in the algorithm
- `build_graph` – (default: `False`) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of δ or the doubling/halving map

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); krc
[[[2, 3], [3, -2]]]
```

We can recover the rigged configuration:

```
sage: ret = RC(krc); ret

0[ ][ ]0

-2[ ][ ]-2
-2[ ][ ]-2

0[ ]0

0[ ]0

sage: elt == ret
True
```

We can also construct and display a graph of the bijection as follows:

```
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(build_graph=True)
sage: view(G, tightpage=True) # not tested
```

to_tensor_product_of_kirillov_reshetikhin_tableaux(*display_steps=False*, *build_graph=False*)

Perform the bijection from this rigged configuration to a tensor product of Kirillov-Reshetikhin tableaux given in [RigConBijection] for single boxes and with [BijectionLRT] and [BijectionDn] for multiple columns and rows.

Note: This is only proven to be a bijection in types $A_n^{(1)}$ and $D_n^{(1)}$, as well as $\bigotimes_i B^{r_i,1}$ and $\bigotimes_i B^{1,s_i}$ for general affine types.

INPUT:

- `display_steps` – (default: `False`) boolean which indicates if we want to print each step in the algorithm
- `build_graph` – (default: `False`) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of δ or the doubling/halving map

OUTPUT:

- The tensor product of KR tableaux element corresponding to this rigged configuration.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).to_tensor_product_of_kirillov_reshetikhin_ta
[[3, 3], [5, 5]]
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: tp_krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krt
[[2, 3], [3, -2]]
```

This is invertible by calling `to_rigged_configuration()`:

```
sage: ret = tp_krt.to_rigged_configuration(); ret

0[ ][ ]0

-2[ ][ ]-2
-2[ ][ ]-2

0[ ]0

0[ ]0

sage: elt == ret
True
```

To view the steps of the bijection in the output, run with the `display_steps=True` option:

```
sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(True)
====================
...
====================

0[ ]0
```

```
-2[ ][ ]-2
 0[ ]0

0[ ]0

0[ ]0

--------------------
[[3, 2]]
--------------------
...
[[2, 3], [3, -2]]
```

We can also construct and display a graph of the bijection as follows:

```
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(build_graph=True)
sage: view(G, tightpage=True) # not tested
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['E', 6, 1], [[2,2]])
sage: map(lambda x: x.weight(), RC.module_generators)
[-4*Lambda[0] + 2*Lambda[2], -2*Lambda[0] + Lambda[2], 0]
sage: KR = crystals.KirillovReshetikhin(['E',6,1], 2,2)
sage: map(lambda x: x.weight(), KR.module_generators) # long time
[0, -2*Lambda[0] + Lambda[2], -4*Lambda[0] + 2*Lambda[2]]

sage: RC = RiggedConfigurations(['D', 6, 1], [[4,2]])
sage: map(lambda x: x.weight(), RC.module_generators)
[-4*Lambda[0] + 2*Lambda[4], -4*Lambda[0] + Lambda[2] + Lambda[4],
 -2*Lambda[0] + Lambda[4], -4*Lambda[0] + 2*Lambda[2],
 -2*Lambda[0] + Lambda[2], 0]
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**RCHWNonSimplyLacedElem**

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RCNonSimplyLacedE

Rigged configurations in highest weight crystals.

TESTS:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['C',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[2],[2]]); ascii_art(elt)
-1[ ]-1  2[ ][ ]2  -2[ ][ ]-2
-1[ ]-1
sage: TestSuite(elt).run()
```

check()

Make sure all of the riggings are less than or equal to the vacancy number.

TESTS:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['C',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[2],[2]])
sage: elt.check()
```

f(*a*)

Return the action of f_a on `self`.

This works by lifting into the virtual configuration, then applying

$$f_a^v = \prod_{j \in \iota(a)} \hat{f}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['C',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[2],[2]])
sage: elt.f(0)
sage: ascii_art(elt.f(1))
0[ ]0   0[ ][ ]0  -1[ ][ ]-1
0[ ]0  -1[ ]-1
sage: elt.f(2)
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.RiggedConfigurations(['C',2,1], La[0])
sage: mg = B.module_generators[0]
sage: mg.f_string([0,1,2]).weight()
2*Lambda[1] - Lambda[2] - delta
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**RCHighestWeightElement**

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurat

Rigged configurations in highest weight crystals.

TESTS:

```
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[1],[2]]); elt

-1[ ]-1
-1[ ]-1

1[ ]1

-1[ ][ ]-1

sage: TestSuite(elt).run()
```

check()

Make sure all of the riggings are less than or equal to the vacancy number.

TESTS:

```
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[1],[2]])
sage: elt.check()
```

f(a)

Return the action of the crystal operator f_a on `self`.

This implements the method defined in [CrysStructSchilling06] which finds the value k which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length k in the a-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label -1. If any of the resulting vacancy numbers are larger than the labels (i.e. it is an invalid rigged configuration), then f_a is undefined.

INPUT:

- a – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[1],[2]])
sage: elt.f(0)

-2[ ][ ]-2
-1[ ]-1

1[ ]1

0[ ][ ]0

sage: elt.f(1)

0[ ]0
0[ ]0

-1[ ]-1
-1[ ]-1

0[ ][ ]0

sage: elt.f(2)
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: mg = B.module_generators[0]
```

```
sage: mg.f_string([0,1,2,0]).weight()
-Lambda[0] + Lambda[1] + Lambda[2] - 2*delta
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**RCNonSimplyLacedElemer**

Bases: sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurat

Rigged configuration elements for non-simply-laced types.

TESTS:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C',2,1])
sage: elt = RC.module_generators[0].f_string([1,0,2,2,0,1]); elt

-2[ ][ ]-1

-2[ ]-1
-2[ ]-1

-2[ ][ ]-1

sage: TestSuite(elt).run()
```

e(a)

Return the action of e_a on `self`.

This works by lifting into the virtual configuration, then applying

$$e_a^v = \prod_{j \in \iota(a)} \hat{e}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C',2,1])
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[-1],[-1,-1],[-1]])
sage: ascii_art(elt.e(0))
0[ ]0  -2[ ]-1  -2[ ][ ]-1
       -2[ ]-1
sage: ascii_art(elt.e(1))
-3[ ][ ]-2  0[ ]1  -3[ ][ ]-2
sage: ascii_art(elt.e(2))
-2[ ][ ]-1  -2[ ]-1  0[ ]0
            -2[ ]-1
```

f(a)

Return the action of f_a on `self`.

This works by lifting into the virtual configuration, then applying

$$f_a^v = \prod_{j \in \iota(a)} \hat{f}_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['C',2,1])
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[-1],[-1,-1],[-1]])
sage: ascii_art(elt.f(0))
-4[ ][ ][ ]-2  -2[ ]-1  -2[ ][ ]-1
                  -2[ ]-1
sage: ascii_art(elt.f(1))
-1[ ][ ]0  -2[ ][ ]-2  -1[ ][ ]0
             -2[ ]-1
sage: ascii_art(elt.f(2))
-2[ ][ ]-1  -2[ ]-1  -4[ ][ ][ ]-2
             -2[ ]-1
```

to_virtual_configuration()

Return the corresponding rigged configuration in the virtual crystal.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt

0[ ][ ][ ]0

0[ ][ ]0
sage: elt.to_virtual_configuration()

0[ ][ ][ ]0

0[ ][ ][ ][ ]0

0[ ][ ][ ]0
```

class sage.combinat.rigged_configurations.rigged_configuration_element.**RiggedConfigurationEle**

Bases: sage.structure.list_clone.ClonableArray

A rigged configuration for simply-laced types.

For more information on rigged configurations, see RiggedConfigurations. For rigged configurations for non-simply-laced types, use RCNonSimplyLacedElement.

Typically to create a specific rigged configuration, the user will pass in the optional argument partition_list and if the user wants to specify the rigging values, give the optional argument rigging_list as well. If rigging_list is not passed, the rigging values are set to the corresponding vacancy numbers.

INPUT:

- parent – the parent of this element
- rigged_partitions – a list of rigged partitions

There are two optional arguments to explicitly construct a rigged configuration. The first is partition_list which gives a list of partitions, and the second is rigging_list which is a list of corresponding lists of riggings. If only partition_list is specified, then it sets the rigging equal to the calculated vacancy numbers.

If we are constructing a rigged configuration from a rigged configuration (say of another type) and we don't want to recompute the vacancy numbers, we can use the use_vacancy_numbers to avoid the recomputation.

EXAMPLES:

Type $A_n^{(1)}$ examples:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2, 2], [2], [2]])

0[ ][ ]0

-2[ ][ ]-2
-2[ ][ ]-2

2[ ][ ]2

-2[ ][ ]-2

sage: RC = RiggedConfigurations(['A', 4, 1], [[1, 1], [1, 1]])
sage: RC(partition_list=[[], [], [], []])

(/)

(/)

(/)

(/)
```

Type $D_n^{(1)}$ examples:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: RC(partition_list=[[3], [3,2], [4], [3]])

-1[ ][ ][ ]-1

1[ ][ ][ ]1
0[ ][ ]0

-3[ ][ ][ ][ ]-3

-1[ ][ ][ ]-1

sage: RC = RiggedConfigurations(['D', 4, 1], [[1, 1], [2, 1]])
sage: RC(partition_list=[[1], [1,1], [1], [1]])

1[ ]1

0[ ]0
0[ ]0

0[ ]0

0[ ]0

sage: elt = RC(partition_list=[[1], [1,1], [1], [1]], rigging_list=[[0], [0,0], [0], [0]]); elt

1[ ]0

0[ ]0
```

```
0[ ]0

0[ ]0

0[ ]0
```

```
sage: from sage.combinat.rigged_configurations.rigged_partition import RiggedPartition
sage: RC2 = RiggedConfigurations(['D', 5, 1], [[2, 1], [3, 1]])
sage: l = [RiggedPartition()] + list(elt)
sage: ascii_art(RC2(*l))
(/)  1[ ]0  0[ ]0  0[ ]0  0[ ]0
            0[ ]0
sage: ascii_art(RC2(*l, use_vacancy_numbers=True))
(/)  1[ ]0  0[ ]0  0[ ]0  0[ ]0
            0[ ]0
```

check()

Check the rigged configuration is properly defined.

There is nothing to check here.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 4])
sage: b = RC.module_generators[0].f_string([1,2,1,1,2,4,2,3,3,2])
sage: b.check()
```

e(a)

Return the action of the crystal operator e_a on `self`.

This implements the method defined in [CrysStructSchilling06] which finds the value k which is the length of the string with the smallest negative rigging of smallest length. Then it removes a box from a string of length k in the a-th rigged partition, keeping all colabels fixed and increasing the new label by one. If no such string exists, then e_a is undefined.

INPUT:

- a – the index of the partition to remove a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
sage: elt.e(1)

(/)

0[ ]0

0[ ]0

-1[ ]-1
```

epsilon(a)

Return ε_a of `self`.

Let x_ℓ be the smallest string of $\nu^{(a)}$ or 0 if $\nu^{(a)} = \emptyset$, then we have $\varepsilon_a = -\min(0, x_\ell)$.

EXAMPLES:

```
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.epsilon(i) for i in I] for rc in RC[:4]])
[0 0]
[1 0]
[0 1]
[0 2]
```

f(*a*)

Return the action of the crystal operator f_a on `self`.

This implements the method defined in [CrysStructSchilling06] which finds the value k which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length k in the a-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label -1. However we need to modify the definition to work for $B(\infty)$ by removing the condition that the resulting rigged configuration is valid.

INPUT:

- `a` – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3])
sage: nu0 = RC.module_generators[0]
sage: nu0.f(2)

(/)

-2[ ]-1

(/)
```

nu()

Return the list ν of rigged partitions of this rigged configuration element.

OUTPUT:

The ν array as a list.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).nu()
[0[ ][ ]0
 , -2[ ][ ]-2
 -2[ ][ ]-2
 , 2[ ][ ]2
 , -2[ ][ ]-2
 ]
```

partition_rigging_lists()

Return the list of partitions and the associated list of riggings of `self`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[1,2],[2,2]])
sage: rc = RC(partition_list=[[2],[1],[1]], rigging_list=[[-1],[0],[-1]]); rc

-1[ ][ ]-1

1[ ]0

-1[ ]-1

sage: rc.partition_rigging_lists()
[[[2], [1], [1]], [[-1], [0], [-1]]]
```

phi(a)

Return φ_a of `self`.

Let x_ℓ be the smallest string of $\nu^{(a)}$ or 0 if $\nu^{(a)} = \emptyset$, then we have $\varepsilon_a = p_\infty^{(a)} - \min(0, x_\ell)$.

EXAMPLES:

```
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.phi(i) for i in I] for rc in RC[:4]])
[1 1]
[0 3]
[0 2]
[1 1]
```

vacancy_number(a, i)

Return the vacancy number $p_i^{(a)}$.

INPUT:

- `a` – the index of the rigged partition
- `i` – the row of the rigged partition

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[1], [2,1], [1], []])
sage: elt.vacancy_number(2, 3)
-2
sage: elt.vacancy_number(2, 2)
-2
sage: elt.vacancy_number(2, 1)
-1

sage: RC = RiggedConfigurations(['D',4,1], [[2,1], [2,1]])
sage: x = RC(partition_list=[[3], [3,1,1], [2], [3,1]]); ascii_art(x)
-1[ ][ ][ ]-1  1[ ][ ][ ]1  0[ ][ ]0  -3[ ][ ][ ]-3
               0[ ]0                  -1[ ]-1
               0[ ]0
sage: x.vacancy_number(2,2)
1
```

5.1.187 Rigged Configurations

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

sage.combinat.rigged_configurations.rigged_configurations.**KirillovReshetikhinCrystal**(*cartan_t*, *r*, *s*)

Return the KR crystal $B^{r,s}$ using rigged configurations.

This is the rigged configuration $RC(B^{r,s})$ or $RC(L)$ with $L = (L_i^{(a)})$ and $L_i^{(a)} = \delta_{a,r}\delta_{i,s}$.

EXAMPLES:

```
sage: K1 = crystals.kirillov_reshetikhin.RiggedConfigurations(['A',6,2], 2, 1)
sage: K2 = crystals.kirillov_reshetikhin.LSPaths(['A',6,2], 2, 1)
sage: K1.digraph().is_isomorphic(K2.digraph(), edge_labels=True)
True
```

TESTS:

We explicitly import and check we get the same crystal:

```
sage: from sage.combinat.rigged_configurations.rigged_configurations import KirillovReshetikhinC
sage: K1 = crystals.kirillov_reshetikhin.RiggedConfigurations(['A',6,2], 2, 1)
sage: K1 is KirillovReshetikhinCrystal(['A',6,2], 2, 1)
True
```

class sage.combinat.rigged_configurations.rigged_configurations.**RCNonSimplyLaced**(*cartan_type*, *dims*)

Bases: sage.combinat.rigged_configurations.rigged_configurations.RiggedConfigurations

Rigged configurations in non-simply-laced types.

These are rigged configurations which lift to virtual rigged configurations in a simply-laced type.

For more on rigged configurations, see RiggedConfigurations.

Element
alias of KRRCNonSimplyLacedElement

from_virtual(*vrc*)
Convert vrc in the virtual crystal into a rigged configution of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret

0[ ][ ][ ]0

0[ ][ ]0
sage: ret == elt
True
```

kleber_tree()
Return the underlying (virtual) Kleber tree used to generate all highest weight rigged configurations.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',3,1], [[1,1], [2,1]])
sage: RC.kleber_tree()
Virtual Kleber tree of Cartan type ['C', 3, 1] and B = ((1, 1), (2, 1))
```

module_generators()

Module generators for this set of rigged configurations.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C', 3, 1], [[1,2]])
sage: for x in RC.module_generators: x

(/)

(/)

(/)

0[ ][ ]0

0[ ][ ]0

0[ ]0

sage: RC = RiggedConfigurations(['D',4,3], [[1,1]])
sage: RC.module_generators
(

     0[ ]0
(/)  0[ ]0

(/)  0[ ]0
   ,
)
```

to_virtual(*rc*)

Convert rc into a rigged configuration in the virtual crystal.

INPUT:

- rc – a rigged configuration element

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt

0[ ][ ][ ]0

0[ ][ ]0
sage: velt = RC.to_virtual(elt); velt

0[ ][ ][ ]0

0[ ][ ][ ][ ]0
```

```
0[ ][ ][ ]0
sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2,
```

virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['C', 2, 1] and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2,
```

class sage.combinat.rigged_configurations.rigged_configurations.**RCTypeA2Dual**(*cartan_type*, *dims*)

Bases: sage.combinat.rigged_configurations.rigged_configurations.RCTypeA2Even

Rigged configurations of type $A_{2n}^{(2)\dagger}$.

For more on rigged configurations, see RiggedConfigurations.

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['BC', 2, 2]^* and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.cardinality()
750
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 1),
sage: RC = RiggedConfigurations(CartanType(['A',2,2]).dual(), [[1,1]])
sage: RC.cardinality()
3
sage: RC = RiggedConfigurations(CartanType(['A',2,2]).dual(), [[1,2],[1,1]])
sage: TestSuite(RC).run() # long time
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,1]])
sage: TestSuite(RC).run() # long time
```

Element

alias of KRRCTypeA2DualElement

from_virtual(*vrc*)

Convert vrc in the virtual crystal into a rigged configution of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration element

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,2]])
sage: elt = RC(partition_list=[[1],[1]])
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret

-1[ ]-1

1[ ]1
```

```
sage: ret == elt
True
```

module_generators()

Module generators for rigged configurations of type $A_{2n}^{(2)\dagger}$.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions. This also skips rigged configurations where $P_i^{(n)} < 1$ when i is odd.

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1,1]])
sage: for x in RC.module_generators: x

(/)

(/)
```

to_virtual(*rc*)

Convert rc into a rigged configuration in the virtual crystal.

INPUT:

- rc – a rigged configuration element

EXAMPLES:

```
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt

-1[ ]-1

1[ ]1

sage: velt = RC.to_virtual(elt); velt

-1[ ]-1

2[ ]2

-1[ ]-1

sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 2), (2, 2))
```

class sage.combinat.rigged_configurations.rigged_configurations.**RCTypeA2Even**(*cartan_type*, *dims*)

Bases: sage.combinat.rigged_configurations.rigged_configurations.RCNonSimplyLaced

Rigged configurations for type $A_{2n}^{(2)}$.

For more on rigged configurations, see RiggedConfigurations.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',4,2], [[2,1], [1,2]])
sage: RC.cardinality()
150
sage: RC = RiggedConfigurations(['A',2,2], [[1,1]])
sage: RC.cardinality()
3
```

```
sage: RC = RiggedConfigurations(['A',2,2], [[1,2],[1,1]])
sage: TestSuite(RC).run() # long time
sage: RC = RiggedConfigurations(['A',4,2], [[2,1]])
sage: TestSuite(RC).run() # long time
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',4,2], [[1,1], [2,2]])
sage: RC.cardinality()
250
```

from_virtual(*vrc*)

Convert `vrc` in the virtual crystal into a rigged configution of the original Cartan type.

INPUT:

- `vrc` – a virtual rigged configuration element

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',4,2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]])
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret

-1[ ]-1

1[ ]1

sage: ret == elt
True
```

to_virtual(*rc*)

Convert `rc` into a rigged configuration in the virtual crystal.

INPUT:

- `rc` – a rigged configuration element

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',4,2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt

-1[ ]-1

1[ ]1

sage: velt = RC.to_virtual(elt); velt

-1[ ]-1

2[ ]2

-1[ ]-1

sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 2), (2, 2))
```

virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',4,2], [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['BC', 2, 2] and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2,
```

class sage.combinat.rigged_configurations.rigged_configurations.**RiggedConfigurations**(*cartan_type*, *B*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Rigged configurations as $U_q'(\mathfrak{g})$-crystals.

Let $\overline{I}$ denote the classical index set associated to the Cartan type of the rigged configurations. A rigged configuration of multiplicity array $L_i^{(a)}$ and dominant weight Λ is a sequence of partitions $\{\nu^{(a)} \mid a \in \overline{I}\}$ such that

$$\sum_{\overline{I} \times \mathbb{Z}_{>0}} i m_i^{(a)} \alpha_a = \sum_{\overline{I} \times \mathbb{Z}_{>0}} i L_i^{(a)} \Lambda_a - \Lambda$$

where α_a is a simple root, Λ_a is a fundamental weight, and $m_i^{(a)}$ is the number of rows of length i in the partition $\nu^{(a)}$.

Each partition $\nu^{(a)}$, in the sequence also comes with a sequence of statistics $p_i^{(a)}$ called *vacancy numbers* and a weakly decreasing sequence $J_i^{(a)}$ of length $m_i^{(a)}$ called *riggings*. Vacancy numbers are computed based upon the partitions and $L_i^{(a)}$, and the riggings must satisfy $\max J_i^{(a)} \leq p_i^{(a)}$. We call such a partition a *rigged partition*. For more, see [RigConBijection] [CrysStructSchilling06] [BijectionLRT].

Rigged configurations form combinatorial objects first introduced by Kerov, Kirillov and Reshetikhin that arose from studies of statistical mechanical models using the Bethe Ansatz. They are sequences of rigged partitions. A rigged partition is a partition together with a label associated to each part that satisfy certain constraints. The labels are also called riggings.

Rigged configurations exist for all affine Kac-Moody Lie algebras. See for example [HKOTT2002]. In Sage they are specified by providing a Cartan type and a list of rectangular shapes B. The list of all (highest weight) rigged configurations for given B is computed via the (virtual) Kleber algorithm (see also KleberTree and VirtualKleberTree).

Rigged configurations in simply-laced types all admit a classical crystal structure [CrysStructSchilling06]. For non-simply-laced types, the crystal is given by using virtual rigged configurations [OSS03]. The highest weight rigged configurations are those where all riggings are nonnegative. The list of all rigged configurations is computed from the highest weight ones using the crystal operators.

Rigged configurations are conjecturally in bijection with TensorProductOfKirillovReshetikhinTableaux of non-exceptional affine types where the list B corresponds to the tensor factors $B^{r,s}$. The bijection has been proven in types $A_n^{(1)}$ and $D_n^{(1)}$ and when the only non-zero entries of $L_i^{(a)}$ are either only $L_1^{(a)}$ or only $L_i^{(1)}$ (corresponding to single columns or rows respectively) [RigConBijection], [BijectionLRT], [BijectionDn].

KR crystals are implemented in Sage, see KirillovReshetikhinCrystal(), however, in the bijection with rigged configurations a different realization of the elements in the crystal are obtained, which are coined KR tableaux, see KirillovReshetikhinTableaux. For more details see [OSS2011].

Note: All non-simply-laced rigged configurations have not been proven to give rise to aligned virtual crystals (i.e. have the correct crystal structure or ismorphic as affine crystals to the tensor product of KR tableaux).

INPUT:

- `cartan_type` – a Cartan type
- `B` – a list of positive integer tuples (r, s) corresponding to the tensor factors in the bijection with tensor product of Kirillov-Reshetikhin tableaux or equivalently the sequence of width s and height r rectangles

REFERENCES:

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2], [1, 1]])
sage: RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (1, 2), (1, 1))

sage: RC = RiggedConfigurations(['A', 3, 1], [[2,1]]); RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1),)
sage: RC.cardinality()
6
sage: len(RC.list()) == RC.cardinality()
True
sage: RC.list() # random
[

                                          0[ ]0
(/)  (/)      (/)      -1[ ]-1  -1[ ]-1
                                          -1[ ]-1
(/)  -1[ ]-1  0[ ]0    0[ ]0    1[ ]1    -1[ ]-1

(/)  (/)      -1[ ]-1  (/)      -1[ ]-1  0[ ]0
   ,        ,        ,        ,        ,
]
```

A rigged configuration element with all riggings equal to the vacancy numbers can be created as follows:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]]); RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (2, 1), (1, 1), (1, 1))
sage: elt = RC(partition_list=[[1],[],[]]); elt

0[ ]0

(/)

(/)
```

If on the other hand we also want to specify the riggings, this can be achieved as follows:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2], [1, 1]])
sage: RC(partition_list=[[2],[2],[2]])

1[ ][ ]1

0[ ][ ]0

0[ ][ ]0
sage: RC(partition_list=[[2],[2],[2]], rigging_list=[[0],[0],[0]])

1[ ][ ]0

0[ ][ ]0
```

```
0[ ][ ]0
```

A larger example:

```
sage: RC = RiggedConfigurations(['D', 7, 1], [[3,3],[5,2],[4,3],[2,3],[4,4],[3,1],[1,4],[2,2]])
sage: elt = RC(partition_list=[[2],[3,2,1],[2,2,1,1],[2,2,1,1,1,1],[3,2,1,1,1,1],[2,1,1],[2,2]],
....:          rigging_list=[[2],[1,0,0],[4,1,2,1],[1,0,0,0,0,0],[0,1,0,0,0,0],[0,0,0],[0,0]])
sage: elt

0[ ][ ]0
0[ ][ ]0
```

To obtain the KR tableau under the bijection between rigged configurations and KR tableaux, we can type the following. This example was checked against Reiho Sakamoto's Mathematica program on rigged configurations:

```
sage: output = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); output
[[1, 1, 1], [2, 3, 3], [3, 4, -5]] (X) [[1, 1], [2, 2], [3, 3], [5, -6], [6, -5]] (X)
[[1, 1, 2], [2, 2, 3], [3, 3, 7], [4, 4, -7]] (X) [[1, 1, 1], [2, 2, 2]] (X)
[[1, 1, 1, 3], [2, 2, 3, 4], [3, 3, 4, 5], [4, 4, 5, 6]] (X) [[1], [2], [3]] (X) [[1, 1, 1, 1]]
sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux().to_rigged_configuration() == elt
True
sage: output.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux() == o
True
```

We can also convert between rigged configurations and tensor products of KR crystals:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1],[1,1],[1],[1]])
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
```

```
[[]]
sage: ret = RC(tp_krc)
sage: ret == elt
True

sage: RC = RiggedConfigurations(['D', 4, 1], [[4,1], [3,3]])
sage: KR1 = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1)
sage: KR2 = crystals.KirillovReshetikhin(['D', 4, 1], 3, 3)
sage: T = crystals.TensorProduct(KR1, KR2)
sage: t = T[1]; t
[[++++, []], [+++-, [[1], [2], [4], [-4]]]]
sage: ret = RC(t)
sage: ret.to_tensor_product_of_kirillov_reshetikhin_crystals()
[[++++, []], [+++-, [[1], [2], [4], [-4]]]]
```

TESTS:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
sage: len(RC.module_generators)
17
sage: RC = RiggedConfigurations(['D', 4, 1], [[1, 1]])
sage: RC.cardinality()
8

sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: c = RC.cardinality(); c
29
sage: K = crystals.KirillovReshetikhin(['D',4,1],2,1)
sage: K.cardinality() == c
True
```

Element
alias of KRRCSimplyLacedElement

cardinality()
Return the cardinality of self.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2]])
sage: RC.cardinality()
100
sage: len(RC.list())
100

sage: RC = RiggedConfigurations(['E', 7, 1], [[1,1]])
sage: RC.cardinality()
134
sage: len(RC.list())
134

sage: RC = RiggedConfigurations(['B', 3, 1], [[2,2],[1,2]])
sage: RC.cardinality()
5130
```

fermionic_formula(*q=None*, *only_highest_weight=False*, *weight=None*)
Return the fermoinic formula associated to self.

Given a set of rigged configurations $RC(\lambda, L)$, the fermonic formula is defined as:

$$M(\lambda, L; q) = \sum_{(\nu,J)} q^{cc(\nu,J)}$$

where we sum over all (classically highest weight) rigged configurations of weight λ where cc is the `cocharge statistic`. This is known to reduce to

$$M(\lambda, L; q) = \sum_{\nu} q^{cc(\nu)} \prod_{(a,i)\in I\times\mathbf{Z}} \begin{bmatrix} p_i^{(a)} + m_i^{(a)} \\ m_i^{(a)} \end{bmatrix}_q .$$

The generating function of $M(\lambda, L; q)$ in the weight algebra subsumes all fermionic formulas:

$$M(L; q) = \sum_{\lambda\in P} M(\lambda, L; q)\lambda.$$

This is conjecturally equal to the `one dimensional configuration sum` of the corresponding tensor product of Kirillov-Reshetikhin crystals, see [HKOTT2002]. This has been proven in general for type $A_n^{(1)}$ [BijectionLRT], single factors $B^{r,s}$ in type $D_n^{(1)}$ [OSS2011] with the result from [Sakamoto13], as well as for a tensor product of single columns [OSS2003], [BijectionDn] or a tensor product of single rows [OSS03] for all non-exceptional types.

INPUT:

- `q` – the variable q
- `only_highest_weight` – use only the classicaly highest weight rigged configurations
- `weight` – return the fermionic formula $M(\lambda, L; q)$ where λ is the classical weight `weight`

REFERENCES:

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 2, 1], [[1,1], [1,1]])
sage: RC.fermionic_formula()
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
 + (q+1)*B[Lambda[1] - Lambda[2]] + B[2*Lambda[1]]
 + B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]

 + (q^4+q^3+q^2)*B[Lambda[3]]
sage: RC = RiggedConfigurations(['D', 4, 2], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True) # long time
(q^2+q)*B[Lambda[1] + Lambda[2] + Lambda[3]] + (q^5+2*q^4+q^3)*B[Lambda[1]
 + Lambda[3]] + (q^3+q^2)*B[2*Lambda[1] + Lambda[3]] + (q^4+q^3+q^2)*B[Lambda[2]
 + Lambda[3]] + B[2*Lambda[2] + Lambda[3]] + (q^6+q^5+q^4)*B[Lambda[3]]
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1],[2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
(q^3+q^2)*B[Lambda[1]] + (q^2+q)*B[Lambda[1] + 2*Lambda[2]]
 + B[Lambda[1] + 4*Lambda[2]] + q*B[3*Lambda[1]] + q*B[4*Lambda[2]]
```

TESTS:

```
sage: RC = RiggedConfigurations(['A', 2, 1], [[1,1], [1,1]])
sage: KR = RC.tensor_product_of_kirillov_reshetikhin_crystals()
sage: RC.fermionic_formula() == KR.one_dimensional_configuration_sum()
True
sage: KT = RC.tensor_product_of_kirillov_reshetikhin_tableaux()
sage: RC.fermionic_formula() == KT.one_dimensional_configuration_sum()
True
sage: RC = RiggedConfigurations(['C', 2, 1], [[2,1], [2,1]])
sage: KR = RC.tensor_product_of_kirillov_reshetikhin_crystals()
sage: RC.fermionic_formula() == KR.one_dimensional_configuration_sum() # long time
True
sage: t = QQ['t'].gen(0)
sage: RC = RiggedConfigurations(['D', 4, 1], [[1,1], [2,1]])
sage: KR = RC.tensor_product_of_kirillov_reshetikhin_crystals()
sage: RC.fermionic_formula(t) == KR.one_dimensional_configuration_sum(t) # long time
True
```

global_options(**get_value*, ***set_value*)

Sets and displays the global options for rigged configurations. If no parameters are set, then the function returns a copy of the options dictionary.

The options to partitions can be accessed as the method RiggedConfigurations.global_options of RiggedConfigurations.

OPTIONS:

- convention – (default: English) Sets the convention used for displaying tableaux and partitions
  - English – use the English convention
  - French – use the French convention
- display – (default: vertical) Specifies how rigged configurations should be printed
  - horizontal – displayed horizontally
  - vertical – displayed vertically

- element_ascii_art – (default: True) display using the repr option element_ascii_art
- half_width_boxes_type_b – (default: True) display the last rigged partition in affine type B as half width boxes
- notation – alternative name for convention

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[2,2],[1,1],[1,1]])
sage: elt = RC(partition_list=[[3,1], [3], [1]])
sage: elt

-3[ ][ ][ ]-3
-1[ ]-1

1[ ][ ][ ]1

-1[ ]-1

sage: RiggedConfigurations.global_options(display="horizontal", convention="french")
sage: elt
-1[ ]-1          1[ ][ ][ ]1    -1[ ]-1
-3[ ][ ][ ]-3
```

Changing the convention for rigged configurations also changes the convention option for tableaux and vice versa:

```
sage: T = Tableau([[1,2,3],[4,5]])
sage: T.pp()
  4  5
  1  2  3
sage: Tableaux.global_options(convention="english")
sage: elt
-3[ ][ ][ ]-3    1[ ][ ][ ]1    -1[ ]-1
-1[ ]-1
sage: T.pp()
  1  2  3
  4  5
sage: RiggedConfigurations.global_options.reset()
```

See GlobalOptions for more features of these options.

kleber_tree()

Return the underlying Kleber tree used to generate all highest weight rigged configurations.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A',3,1], [[1,1], [2,1]])
sage: RC.kleber_tree()
Kleber tree of Cartan type ['A', 3, 1] and B = ((1, 1), (2, 1))
```

module_generators()

Module generators for this set of rigged configurations.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[2,1]])
sage: for x in RC.module_generators: x
```

```
(/)

(/)

(/)

(/)

0[ ]0

0[ ]0
0[ ]0

0[ ]0

0[ ]0
```

TESTS:

We check that this works with relabelled Cartan types (trac ticket #16876):

```
sage: ct = CartanType(['A',3,1]).relabel(lambda x: x+2)
sage: RC = RiggedConfigurations(ct, [[4,1],[5,1]])
sage: len(RC.module_generators)
2
sage: ct = CartanType(['A',3,1]).relabel(lambda x: (x+2) % 4)
sage: RC = RiggedConfigurations(ct, [[0,1],[1,1]])
sage: len(RC.module_generators)
2
```

tensor(**crystals*, ***options*)

Return the tensor product of `self` with `crystals`.

If `crystals` is a list of rigged configurations of the same Cartan type, then this returns a new `RiggedConfigurations`.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[2,1],[1,3]])
sage: RC2 = RiggedConfigurations(['A', 3, 1], [[1,1], [3,3]])
sage: RC.tensor(RC2, RC2)
Rigged configurations of type ['A', 3, 1]
 and factor(s) ((2, 1), (1, 3), (1, 1), (3, 3), (1, 1), (3, 3))

sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: RC.tensor(K)
Full tensor product of the crystals
 [Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1), (1, 3)),
  Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2)]
```

tensor_product_of_kirillov_reshetikhin_crystals()

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,1],[2,2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_crystals()
Full tensor product of the crystals
[Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1),
```

```
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)]
```

tensor_product_of_kirillov_reshetikhin_tableaux()
Return the corresponding tensor product of Kirillov-Reshetikhin tableaux.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_tableaux()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((3, 2), (
```

5.1.188 Rigged Partitions

Class and methods of the rigged partition which are used by the rigged configuration class. This is an internal class used by the rigged configurations and KR tableaux during the bijection, and is not to be used by the end-user.

We hold the partitions as an 1-dim array of positive integers where each value corresponds to the length of the row. This is the shape of the partition which can be accessed by the regular index.

The data for the vacancy number is also stored in a 1-dim array which each entry corresponds to the row of the tableau, and similarly for the partition values.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

Todo

Convert this to using multiplicities m_i (perhaps with a dictionary?)?

---

class sage.combinat.rigged_configurations.rigged_partition.**RiggedPartition**(*shape=None*, *rigging_list=None*, *vacancy_nums=None*)

Bases: sage.combinat.combinat.CombinatorialObject

The RiggedPartition class which is the data structure of a rigged (i.e. marked or decorated) Young diagram of a partition.

Note that this class as a stand-alone object does not make sense since the vacancy numbers are calculated using the entire rigged configuration. For more, see RiggedConfigurations.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP
 0[ ][ ]0
-1[ ]-1

sage: type(RP)
<class 'sage.combinat.rigged_configurations.rigged_partition.RiggedPartition'>
```

get_num_cells_to_column(*end_column*, *t=1*)
Get the number of cells in all columns before the end_column.

INPUT:

- `end_column` – The index of the column to end at
- `t` – The scaling factor

OUTPUT:

- The number of cells

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.get_num_cells_to_column(1)
2
sage: RP.get_num_cells_to_column(2)
3
sage: RP.get_num_cells_to_column(3)
3
sage: RP.get_num_cells_to_column(3, 2)
5
```

insert_cell(*max_width*)

Insert a cell given at a singular value as long as its less than the specified width.

Note that `insert_cell()` does not update riggings or vacancy numbers, but it does prepare the space for them. Returns the width of the row we inserted at.

INPUT:

- `max_width` – The maximum width (i.e. row length) that we can insert the cell at

OUTPUT:

- The width of the row we inserted at.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.insert_cell(2)
2
sage: RP
 0[ ][ ][ ]None
-1[ ]-1
```

remove_cell(*row*, *num_cells=1*)

Removes a cell at the specified `row`.

Note that `remove_cell()` does not set/update the vacancy numbers or the riggings, but guarantees that the location has been allocated in the returned index.

INPUT:

- `row` – The row to remove the cell from
- `num_cells` – (Default: 1) The number of cells to remove

OUTPUT:

- The location of the newly constructed row or `None` if unable to remove row or if deleted a row.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])[2]
sage: RP.remove_cell(0)
```

```
0
sage: RP
 0[ ]0
-1[ ]-1
```

class sage.combinat.rigged_configurations.rigged_partition.**RiggedPartitionTypeB**(*arg0*, *arg1=None*, *arg2=None*)

Bases: sage.combinat.rigged_configurations.rigged_partition.RiggedPartition

Rigged partitions for type $B_n^{(1)}$ which has special printing rules which comes from the fact that the n-th partition can have columns of width $\frac{1}{2}$.

5.1.189 Tensor Product of Kirillov-Reshetikhin Tableaux

A tensor product of KirillovReshetikhinTableaux which are tableaux of r rows and s columns which naturally arise in the bijection between rigged configurations and tableaux and which are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{r,s}$, see KirillovReshetikhinCrystal().

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

EXAMPLES:

Type $A_n^{(1)}$ examples:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2,1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((3, 1), (2, 1))
sage: KRT.cardinality()
24
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1,1], [2,1], [3,1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 1), (2, 1), (
sage: len(KRT.module_generators)
5
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1,1], [2,1], [3,1]])
sage: KRT.cardinality()
96
```

Type $D_n^{(1)}$ examples:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[1, 1], [2, 1], [1, 1]]
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and factor(s) ((1, 1), (2, 1), (
sage: T = KRT(pathlist=[[1], [-2, 2], [1]])
sage: T
[[1]] (X) [[2], [-2]] (X) [[1]]
sage: T2 = KRT(pathlist=[[1], [2, -2], [1]])
sage: T2
[[1]] (X) [[-2], [2]] (X) [[1]]
sage: T == T2
False
```

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.**HighestWeightTensorKRT**(*t*

Bases: sage.structure.unique_representation.UniqueRepresentation

Class so we do not have to build the module generators for TensorProductOfKirillovReshetikhinTableaux at initialization.

Warning: This class is for internal use only!

cardinality()

Return the cardinality of self which is the number of highest weight elements.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[2,2]])
sage: from sage.combinat.rigged_configurations.tensor_product_kr_tableaux import HighestWeig
sage: HW = HighestWeightTensorKRT(KRT)
sage: HW.cardinality()
3
sage: len(HW)
3
sage: len(KRT.module_generators)
3
```

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.**TensorProductOfKirillovR**

Bases: sage.combinat.crystals.tensor_product.FullTensorProductOfRegularCrystals

A tensor product of KirillovReshetikhinTableaux.

Through the bijection with rigged configurations, the tableaux that are produced in all nonexceptional types are all of rectangular shapes and do not necessarily obey the usual strict increase in columns and weak increase in rows. The relation between the elements of the Kirillov-Reshetikhin crystal, given by the Kashiwara-Nakashima tableaux, and the Kirillov-Reshetikhin tableaux is given by a filling map.

Note: The tableaux for all non-simply-laced types are provably correct if the bijection with rigged configurations holds. Therefore this is currently only proven for $B^{r,1}$ or $B^{1,s}$ and in general for types $A_n^{(1)}$ and $D_n^{(1)}$.

For more information see [OSS2011] and KirillovReshetikhinTableaux.

For more information on KR crystals, see sage.combinat.crystals.kirillov_reshetikhin.

INPUT:

- cartan_type – a Cartan type
- B – an (ordered) list of pairs (r, s) which give the dimension of a rectangle with r rows and s columns and corresponds to a Kirillov-Reshetikhin tableaux factor of $B^{r,s}$.

REFERENCES:

EXAMPLES:

We can go between tensor products of KR crystals and rigged configurations:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1],[2,2]])
sage: tp_krt = KRT(pathlist=[[3,2,1],[3,2,3,2]]); tp_krt
[[1], [2], [3]] (X) [[2, 2], [3, 3]]
sage: RC = RiggedConfigurations(['A',3,1], [[3,1],[2,2]])
sage: rc_elt = tp_krt.to_rigged_configuration(); rc_elt

-2[ ][ ]-2

0[ ][ ]0
```

```
(/)

sage: tp_krc = tp_krt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[1], [2], [3]], [[2, 2], [3, 3]]]
sage: KRT(tp_krc) == tp_krt
True
sage: rc_elt == tp_krt.to_rigged_configuration()
True
sage: KR1 = crystals.KirillovReshetikhin(['A',3,1], 3,1)
sage: KR2 = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: T = crystals.TensorProduct(KR1, KR2)
sage: t = T(KR1(3,2,1), KR2(3,2,3,2))
sage: KRT(t) == tp_krt
True
sage: t == tp_krc
True
```

We can get the highest weight elements by using the attribute `module_generators`:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2,1]])
sage: list(KRT.module_generators)
[[[1], [2], [3]] (X) [[1], [2]], [[1], [3], [4]] (X) [[1], [2]]]
```

To create elements directly (i.e. not passing in KR tableaux elements), there is the **pathlist** option will receive a list of lists which contain the reversed far-eastern reading word of the tableau. That is to say, in English notation, the word obtain from reading bottom-to-top, left-to-right.

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,2], [1,2], [2,1]]
sage: elt = KRT(pathlist=[[3, 2, 1, 4, 2, 1], [1, 3], [3, 1]])
sage: elt.pp()
  1  1 (X)    1  3 (X)    1
  2  2                    3
  3  4
```

One can still create elements in the same way as tensor product of crystals:

```
sage: K1 = crystals.KirillovReshetikhin(['A',3,1], 3, 2, model='KR')
sage: K2 = crystals.KirillovReshetikhin(['A',3,1], 1, 2, model='KR')
sage: K3 = crystals.KirillovReshetikhin(['A',3,1], 2, 1, model='KR')
sage: eltlong = KRT(K1(3, 2, 1, 4, 2, 1), K2(1, 3), K3(3, 1))
sage: eltlong == elt
True
```

Element
alias of `TensorProductOfKirillovReshetikhinTableauxElement`

rigged_configurations()
Return the corresponding set of rigged configurations.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1,3], [2,1]])
sage: KRT.rigged_configurations()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 3), (2, 1))
```

tensor(**crystals*, ***options*)
Return the tensor product of `self` with `crystals`.

If `crystals` is a list of (a tensor product of) KR tableaux, this returns a `TensorProductOfKirillovReshetikhinTableaux`.

EXAMPLES:

```
sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1,3],[3,1]])
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP.tensor(K, TP)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
 and factor(s) ((1, 3), (3, 1), (2, 2), (1, 3), (3, 1))

sage: C = crystals.KirillovReshetikhin(['A',3,1], 3, 1, model='KN')
sage: TP.tensor(K, C)
Full tensor product of the crystals
 [Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (1, 3),
  Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (3, 1),
  Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
  Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]
```

tensor_product_of_kirillov_reshetikhin_crystals()

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1],[2,2]])
sage: KRT.tensor_product_of_kirillov_reshetikhin_crystals()
Full tensor product of the crystals [Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)]
```

TESTS:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[4,1], [3,3]])
sage: KR1 = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1)
sage: KR2 = crystals.KirillovReshetikhin(['D', 4, 1], 3, 3)
sage: T = crystals.TensorProduct(KR1, KR2)
sage: T == KRT.tensor_product_of_kirillov_reshetikhin_crystals()
True
sage: T is KRT.tensor_product_of_kirillov_reshetikhin_crystals()
True
```

5.1.190 Tensor Product of Kirillov-Reshetikhin Tableaux Elements

A tensor product of KirillovReshetikhinTableauxElement.

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux_element.**TensorProductOfK**

Bases: sage.combinat.crystals.tensor_product.TensorProductOfRegularCrystalsElement

An element in a tensor product of Kirillov-Reshetikhin tableaux.

For more on tensor product of Kirillov-Reshetikhin tableaux, see TensorProductOfKirillovReshetikhinTableaux.

The most common way to construct an element is to specify the option pathlist which is a list of lists which will be used to generate the individual factors of KirillovReshetikhinTableauxElement.

EXAMPLES:

Type $A_n^{(1)}$ examples:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[1,1], [2,1], [1,1
sage: T = KRT(pathlist=[[2], [4,1], [3], [4,2], [3,1], [2,1]])
sage: T
[[2]] (X) [[1], [4]] (X) [[3]] (X) [[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()

0[ ]0
0[ ]0
```

```
1[ ]0

1[ ]0

sage: T.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux()
[[2], [3]] (X) [[1]] (X) [[-1]] (X) [[1]]
```

classical_weight()

Return the classical weight of `self`.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[2,2]])
sage: elt = KRT(pathlist=[[3,2,-1,1]]); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt
[[1, 2], [2, 3]] (X) [[1, 4, 4]]
sage: elt.classical_weight()
(2, 2, 1, 2)
```

left_split()

Return the image of `self` under the left column splitting map.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt.pp()
  1  2 (X)   1  4  4
  2  3
sage: elt.left_split().pp()
  1 (X)   2 (X)   1  4  4
  2       3
```

lusztig_involution()

Return the result of the classical Lusztig involution on `self`.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]])
sage: li = elt.lusztig_involution(); li
[[1, 1, 4]] (X) [[2, 3], [3, 4]]
sage: li.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 3), (
```

pp()

Pretty print `self`.

EXAMPLES:

```
sage: TPKRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',4,1], [[2,2],[3,1],[3
sage: TPKRT.module_generators[0].pp()
  1  1 (X)   1 (X)   1  1  1
  2  2       2       2  2  2
             3       3  3  3
```

right_split()

Return the image of `self` under the right column splitting map.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt.pp()
  1  2 (X)   1  4  4
  2  3
sage: elt.right_split().pp()
  1  2 (X)   1  4 (X)   4
  2  3
```

Let $*$ denote the `Lusztig involution`, we check that $* \circ \mathrm{ls} \circ * = \mathrm{rs}$:

```
sage: all(x.lusztig_involution().left_split().lusztig_involution() == x.right_split() for x
True
```

to_rigged_configuration (*display_steps=False*)

Perform the bijection from `self` to a `rigged configuration` which is described in [RigConBijection], [BijectionLRT], and [BijectionDn].

Note: This is only proven to be a bijection in types $A_n^{(1)}$ and $D_n^{(1)}$, as well as $\bigotimes_i B^{r_i,1}$ and $\bigotimes_i B^{1,s_i}$ for general affine types.

INPUT:

- `display_steps` – (default: `False`) Boolean which indicates if we want to output each step in the algorithm.

OUTPUT:

The rigged configuration corresponding to `self`.

EXAMPLES:

Type $A_n^{(1)}$ example:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[2,1], [2,1],
sage: T = KRT(pathlist=[[4, 2], [3, 1], [2, 1]])
sage: T
[[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()

0[ ]0

1[ ]1
1[ ]0

0[ ]0
```

Type $D_n^{(1)}$ example:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,2]])
sage: T = KRT(pathlist=[[2,1,4,3]])
sage: T
[[1, 3], [2, 4]]
sage: T.to_rigged_configuration()

0[ ]0

-1[ ]-1
-1[ ]-1
```

```
0[ ]0

(/)
```

Type $D_n^{(1)}$ spinor example:

```
sage: CP = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 5, 1], [[5,1],[2,1],[1,
sage: elt = CP(pathlist=[[-2,-5,4,3,1],[-1,2],[1],[1],[1]])
sage: elt
[[1], [3], [4], [-5], [-2]] (X) [[2], [-1]] (X) [[1]] (X) [[1]] (X) [[1]]
sage: elt.to_rigged_configuration()

2[ ][ ]1

0[ ][ ]0
0[ ]0

0[ ][ ]0
0[ ]0

0[ ]0

0[ ][ ]0
```

This is invertible by calling `to_tensor_product_of_kirillov_reshetikhin_tableaux()`:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[2,2]])
sage: T = KRT(pathlist=[[2,1,4,3]])
sage: rc = T.to_rigged_configuration()
sage: ret = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux(); ret
[[1, 3], [2, 4]]
sage: ret == T
True
```

to_tensor_product_of_kirillov_reshetikhin_crystals()

Return a tensor product of Kirillov-Reshetikhin crystals corresponding to `self`.

This works by performing the filling map on each individual factor. For more on the filling map, see `KirillovReshetikhinTableaux`.

EXAMPLES:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[1,1],[2,2]])
sage: elt = KRT(pathlist=[[-1],[-1,2,-1,1]]); elt
[[-1]] (X) [[2, 1], [-1, -1]]
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[-1]], [[2], [-1]]]
```

We can recover the original tensor product of KR tableaux:

```
sage: ret = KRT(tp_krc); ret
[[-1]] (X) [[2, 1], [-1, -1]]
sage: ret == elt
True
```

5.1.192 Root system features that are imported by default in the interpreter namespace

5.1.193 Ambient lattices and ambient spaces

class sage.combinat.root_system.ambient_space.**AmbientSpace**(*root_system*, *base_ring*)
Bases: sage.misc.cachefunc.ClearCacheOnPickle, sage.combinat.free_module.CombinatorialFree

Abstract class for ambient spaces

All subclasses should implement a class method `smallest_base_ring` taking a Cartan type as input, and a method `dimension` working on a partially initialized instance with just `root_system` as attribute. There is no safe default implementation for the later, so none is provided.

EXAMPLES:

```
sage: AL = RootSystem(['A',2]).ambient_lattice()
```

Note: This is only used so far for finite root systems.

Caveat: Most of the ambient spaces currently have a basis indexed by $0, \ldots, n$, unlike the usual mathematical convention:

```
sage: e = AL.basis()
sage: e[0], e[1], e[2]
((1, 0, 0), (0, 1, 0), (0, 0, 1))
```

This will be cleaned up!

- sage.combinat.root_system.type_G.AmbientSpace
- sage.combinat.root_system.type_dual.AmbientSpace
- sage.combinat.root_system.type_affine.AmbientSpace

TESTS:

```
sage: types = CartanType.samples(crystallographic = True)+[CartanType(["A",2],["C",5])]
sage: for e in [ct.root_system().ambient_space() for ct in types]:
...           TestSuite(e).run()
```

coroot_lattice()

EXAMPLES:

```
sage: e = RootSystem(["A", 3]).ambient_lattice()
sage: e.coroot_lattice()
Ambient lattice of the Root system of type ['A', 3]
```

dimension()

Returns the dimension of this ambient space.

EXAMPLES:

```
sage: from sage.combinat.root_system.ambient_space import AmbientSpace
sage: e = RootSystem(['F',4]).ambient_space()
sage: AmbientSpace.dimension(e)
Traceback (most recent call last):
...
NotImplementedError
```

from_vector_notation(*weight*, *style='lattice'*)

INPUT:

- `weight` - a vector or tuple representing a weight

Returns an element of self. If the weight lattice is not of full rank, it coerces it into the weight lattice, or its ambient space by orthogonal projection. This arises in two cases: for SL(r+1), the weight lattice is contained in a hyperplane of codimension one in the ambient, space, and for types E6 and E7, the weight lattice is contained in a subspace of codimensions 2 or 3, respectively.

If style="coroots" and the data is a tuple of integers, it is assumed that the data represent a linear combination of fundamental weights. If style="coroots", and the root lattice is not of full rank in the ambient space, it is projected into the subspace corresponding to the semisimple derived group. This arises with Cartan type A, E6 and E7.

EXAMPLES:

```
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0,0))
(1, 0, 0)
sage: RootSystem("A2").ambient_space().from_vector_notation([1,0,0])
(1, 0, 0)
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0),style="coroots")
(2/3, -1/3, -1/3)
```

fundamental_weight(*i*)

Returns the fundamental weight Λ_i in `self`

In several of the ambient spaces, it is more convenient to construct all fundamental weights at once. To support this, we provide this default implementation of `fundamental_weight` using the method `fundamental_weights`. Beware that this will cause a loop if neither `fundamental_weight` nor `fundamental_weights` is implemented.

EXAMPLES:

```
sage: e =  RootSystem(['F',4]).ambient_space()
sage: e.fundamental_weight(3)
(3/2, 1/2, 1/2, 1/2)
```

```
sage: e =  RootSystem(['G',2]).ambient_space()
sage: e.fundamental_weight(1)
(1, 0, -1)

sage: e =  RootSystem(['E',6]).ambient_space()
sage: e.fundamental_weight(3)
(-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6)
```

reflection(*root*, *coroot=None*)

EXAMPLES:

```
sage: e = RootSystem(["A", 3]).ambient_lattice()
sage: a = e.simple_root(0); a
(-1, 0, 0, 0)
sage: b = e.simple_root(1); b
(1, -1, 0, 0)
sage: s_a = e.reflection(a)
sage: s_a(b)
(0, -1, 0, 0)
```

simple_coroot(*i*)

Returns the i-th simple coroot, as an element of this space

EXAMPLES:

```
sage: R = RootSystem(["A",3])
sage: L = R.ambient_lattice()
sage: L.simple_coroot(1)
(1, -1, 0, 0)
sage: L.simple_coroot(2)
(0, 1, -1, 0)
sage: L.simple_coroot(3)
(0, 0, 1, -1)
```

classmethod smallest_base_ring(*cartan_type=None*)

Returns the smallest ground ring over which the ambient space can be realized.

This class method will get called with the Cartan type as input. This default implementation returns $\mathbf{Q}$; subclasses should override it as appropriate.

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.smallest_base_ring()
Rational Field
```

to_ambient_space_morphism()

Return the identity map on `self`.

This is present for uniformity of use; the corresponding method for abstract root and weight lattices/spaces, is not trivial.

EXAMPLES:

```
sage: P = RootSystem(['A',2]).ambient_space()
sage: f = P.to_ambient_space_morphism()
sage: p = P.an_element()
sage: p
(2, 2, 3)
sage: f(p)
(2, 2, 3)
```

```
sage: f(p)==p
True
```

class sage.combinat.root_system.ambient_space.**AmbientSpaceElement**(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

associated_coroot()

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: a = e.simple_root(0); a
(1/2, -1/2, -1/2, -1/2)
sage: a.associated_coroot()
(1, -1, -1, -1)
```

coerce_to_e6()

For type E7 or E8, orthogonally projects an element of the root lattice into the E6 root lattice. This operation on weights corresponds to intersection with the semisimple subgroup E6.

EXAMPLES:

```
sage: [b.coerce_to_e6() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0), (0, 0, 1, 0, 0, 0, 0, 0),
(0, 0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3),
(0, 0, 0, 0, 0, 1/3, 1/3, -1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3)]
```

coerce_to_e7()

For type E8, this orthogonally projects the given element of the E8 root lattice into the E7 root lattice. This operation on weights corresponds to intersection with the semisimple subgroup E7.

EXAMPLES:

```
sage: [b.coerce_to_e7() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0),
 (0, 0, 1, 0, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0, 0),
 (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1, 0, 0),
 (0, 0, 0, 0, 0, 0, 1/2, -1/2), (0, 0, 0, 0, 0, 0, -1/2, 1/2)]
```

coerce_to_sl()

For type ['A',r], this coerces the element of the ambient space into the root space by orthogonal projection. The root space has codimension one and corresponds to the Lie algebra of SL(r+1,CC), whereas the full weight space corresponds to the Lie algebra of GL(r+1,CC). So this operation corresponds to multiplication by a (possibly fractional) power of the determinant to give a weight determinant one.

EXAMPLES:

```
sage: [fw.coerce_to_sl() for fw in RootSystem("A2").ambient_space().fundamental_weights()]
[(2/3, -1/3, -1/3), (1/3, 1/3, -2/3)]
sage: L = RootSystem("A2xA3").ambient_space()
```

```
sage: L([1,2,3,4,5,0,0]).coerce_to_sl()
(-1, 0, 1, 7/4, 11/4, -9/4, -9/4)
```

dot_product (*lambdacheck*)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

inner_product (*lambdacheck*)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

is_positive_root()

EXAMPLES:

```
sage: R = RootSystem(['A',3]).ambient_space()
sage: r=R.simple_root(1)+R.simple_root(2)
sage: r.is_positive_root()
True
sage: r=R.simple_root(1)-R.simple_root(2)
sage: r.is_positive_root()
False
```

scalar (*lambdacheck*)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```

to_ambient()

Map `self` to the ambient space.

This exists for uniformity. Its analogue for root and weight lattice realizations, is not trivial.

EXAMPLES:

```
sage: v = CartanType(['C',3]).root_system().ambient_space().an_element(); v
(2, 2, 3)
sage: v.to_ambient()
(2, 2, 3)
```

5.1.194 Associahedron

Todo

- fix adjacency matrix
- edit graph method to get proper vertex labellings
- UniqueRepresentation?

AUTHORS:

- Christian Stump

class sage.combinat.root_system.associahedron.**Associahedra**(*base_ring*, *ambient_dim*)
Bases: sage.geometry.polyhedron.parent.Polyhedra_QQ_ppl

Parent of Associahedra of specified dimension

EXAMPLES:

```
sage: from sage.combinat.root_system.associahedron import Associahedra
sage: parent = Associahedra(QQ,2);  parent
Polyhedra in QQ^2
sage: type(parent)
<class 'sage.combinat.root_system.associahedron.Associahedra_with_category'>
sage: parent(['A',2])
Generalized associahedron of type ['A', 2] with 5 vertices
```

Importantly, the parent knows the dimension of the ambient space. If you try to construct an associahedron of a different dimension, a ValueError is raised:

```
sage: parent(['A',3])
Traceback (most recent call last):
...
ValueError: V-representation data requires a list of length ambient_dim
```

Element
alias of Associahedron_class

sage.combinat.root_system.associahedron.**Associahedron**(*cartan_type*)
Construct an associahedron.

The generalized associahedron is a polytopal complex with vertices in one-to-one correspondence with clusters in the cluster complex, and with edges between two vertices if and only if the associated two clusters intersect in codimension 1.

The associahedron of type A_n is one way to realize the classical associahedron as defined in the Wikipedia article Associahedron.

A polytopal realization of the associahedron can be found in [CFZ]. The implementation is based on [CFZ], Theorem 1.5, Remark 1.6, and Corollary 1.9.

EXAMPLES:

```
sage: Asso = polytopes.associahedron(['A',2]); Asso
Generalized associahedron of type ['A', 2] with 5 vertices

sage: sorted(Asso.Hrepresentation(), key=repr)
[An inequality (-1, 0) x + 1 >= 0,
 An inequality (0, -1) x + 1 >= 0,
 An inequality (0, 1) x + 1 >= 0,
```

```
 An inequality (1, 0) x + 1 >= 0,
 An inequality (1, 1) x + 1 >= 0]

sage: Asso.Vrepresentation()
(A vertex at (1, -1), A vertex at (1, 1), A vertex at (-1, 1),
 A vertex at (-1, 0), A vertex at (0, -1))

sage: polytopes.associahedron(['B',2])
Generalized associahedron of type ['B', 2] with 6 vertices
```

The two pictures of [CFZ] can be recovered with:

```
sage: Asso = polytopes.associahedron(['A',3]); Asso
Generalized associahedron of type ['A', 3] with 14 vertices
sage: Asso.plot()
Graphics3d Object

sage: Asso = polytopes.associahedron(['B',3]); Asso
Generalized associahedron of type ['B', 3] with 20 vertices
sage: Asso.plot()
Graphics3d Object
```

TESTS:

```
sage: sorted(polytopes.associahedron(['A',3]).vertices())
[A vertex at (-3/2, 0, -1/2), A vertex at (-3/2, 0, 3/2),
 A vertex at (-3/2, 1, -3/2), A vertex at (-3/2, 2, -3/2),
 A vertex at (-3/2, 2, 3/2), A vertex at (-1/2, -1, -1/2),
 A vertex at (-1/2, 0, -3/2), A vertex at (1/2, -2, 1/2),
 A vertex at (1/2, -2, 3/2), A vertex at (3/2, -2, 1/2),
 A vertex at (3/2, -2, 3/2), A vertex at (3/2, 0, -3/2),
 A vertex at (3/2, 2, -3/2), A vertex at (3/2, 2, 3/2)]

sage: sorted(polytopes.associahedron(['B',3]).vertices())
[A vertex at (-3, 0, 0), A vertex at (-3, 0, 3),
 A vertex at (-3, 2, -2), A vertex at (-3, 4, -3),
 A vertex at (-3, 5, -3), A vertex at (-3, 5, 3),
 A vertex at (-2, 1, -2), A vertex at (-2, 3, -3),
 A vertex at (-1, -2, 0), A vertex at (-1, -1, -1),
 A vertex at (1, -4, 1), A vertex at (1, -3, 0),
 A vertex at (2, -5, 2), A vertex at (2, -5, 3),
 A vertex at (3, -5, 2), A vertex at (3, -5, 3),
 A vertex at (3, -3, 0), A vertex at (3, 3, -3),
 A vertex at (3, 5, -3), A vertex at (3, 5, 3)]

sage: polytopes.associahedron(['A',4]).f_vector()
(1, 42, 84, 56, 14, 1)
sage: polytopes.associahedron(['B',4]).f_vector()
(1, 70, 140, 90, 20, 1)
```

class sage.combinat.root_system.associahedron.**Associahedron_class**(*parent*, *Vrep*, *Hrep*, ***kwds*)

Bases: sage.geometry.polyhedron.backend_ppl.Polyhedron_QQ_ppl

The Python class of an associahedron

You should use the Associahedron() convenience function to construct associahedra from the Cartan type.

TESTS:

```
sage: Asso = polytopes.associahedron(['A',2]); Asso
Generalized associahedron of type ['A', 2] with 5 vertices
sage: TestSuite(Asso).run()
```

cartan_type()
Return the Cartan type of `self`.

EXAMPLES:

```
sage: polytopes.associahedron(['A',3]).cartan_type()
['A', 3]
```

vertices_in_root_space()
Return the vertices of `self` as elements in the root space.

EXAMPLES:

```
sage: Asso = polytopes.associahedron(['A',2])
sage: Asso.vertices()
(A vertex at (1, -1), A vertex at (1, 1),
 A vertex at (-1, 1), A vertex at (-1, 0),
 A vertex at (0, -1))

sage: Asso.vertices_in_root_space()
(alpha[1] - alpha[2], alpha[1] + alpha[2], -alpha[1] + alpha[2],
-alpha[1], -alpha[2])
```

5.1.195 Branching Rules

class sage.combinat.root_system.branching_rules.**BranchingRule**(*R*, *S*, *f*, *name='default'*, *intermediate_types=[]*, *intermediate_names=[]*)

Bases: sage.structure.sage_object.SageObject

A class for branching rules.

Rtype()
In a branching rule R => S, returns the Cartan Type of the ambient group R.

EXAMPLES:

```
sage: branching_rule("A3","A2","levi").Rtype()
['A', 3]
```

Stype()
In a branching rule R => S, returns the Cartan Type of the subgroup S.

EXAMPLES:

```
sage: branching_rule("A3","A2","levi").Stype()
['A', 2]
```

branch(*chi*, *style=None*)
INPUT:

- `chi` – A character of the WeylCharacterRing with Cartan type self.Rtype().

Returns the branched character.

EXAMPLES:

```
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: chi=G2(1,1); chi.degree()
64
sage: b=G2.maximal_subgroup("A2"); b
extended branching rule G2 => A2
sage: b.branch(chi)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
sage: A2=WeylCharacterRing("A2",style="coroots"); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: chi.branch(A2,rule=b)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
```

describe(*verbose=False*, *debug=False*, *no_r=False*)

Describes how extended roots restrict under self.

EXAMPLES:

```
sage: branching_rule("G2","A2","extended").describe()

3
O=<=O---O
1   2   0
G2~

root restrictions G2 => A2:

O---O
1   2
A2

0 => 2
2 => 1

For more detailed information use verbose=True
```

In this example, 0 is the affine root, that is, the negative of the highest root, for "$G2$". If i => j is printed, this means that the i-th simple (or affine) root of the ambient group restricts to the j-th simple root of the subgroup. For reference the Dynkin diagrams are also printed. The extended Dynkin diagram of the ambient group is printed if the affine root restricts to a simple root. More information is printed if the parameter *verbose* is true.

sage.combinat.root_system.branching_rules.**branch_weyl_character**(*chi*, *R*, *S*, *rule='default'*)

A branching rule describes the restriction of representations from a Lie group or algebra G to a subgroup H. See for example, R. C. King, Branching rules for classical Lie groups using tensor and spinor methods. J. Phys. A 8 (1975), 429-449, Howe, Tan and Willenbring, Stable branching rules for classical symmetric pairs, Trans. Amer. Math. Soc. 357 (2005), no. 4, 1601-1626, McKay and Patera, Tables of Dimensions, Indices and Branching Rules for Representations of Simple Lie Algebras (Marcel Dekker, 1981), and Fauser, Jarvis, King and Wybourne, New branching rules induced by plethysm. J. Phys. A 39 (2006), no. 11, 2611–2655. If $H \subset G$ we will write $G \Rightarrow H$ to denote the branching rule, which is a homomorphism of WeylCharacterRings.

INPUT:

- `chi` – a character of G
- `R` – the Weyl Character Ring of G

- S – the Weyl Character Ring of H
- rule – an element of the BranchingRule class or one (most usually) a keyword such as:
  - "levi"
  - "automorphic"
  - "symmetric"
  - "extended"
  - "orthogonal_sum"
  - "tensor"
  - "triality"
  - "miscellaneous"

The BranchingRule class is a wrapper for functions from the weight lattice of G to the weight lattice of H. An instance of this class encodes an embedding of H into G. The usual way to specify an embedding is to supply a keyword, which tells Sage to use one of the built-in rules. We will discuss these first.

To explain the predefined rules, we survey the most important branching rules. These may be classified into several cases, and once this is understood, the detailed classification can be read off from the Dynkin diagrams. Dynkin classified the maximal subgroups of Lie groups in Mat. Sbornik N.S. 30(72):349-462 (1952).

We will list give predefined rules that cover most cases where the branching rule is to a maximal subgroup. For convenience, we also give some branching rules to subgroups that are not maximal. For example, a Levi subgroup may or may not be maximal.

For example, there is a "levi" branching rule defined from $SL(5)$ (with Cartan type A_4) to $SL(4)$ (with Cartan type A_3), so we may compute the branching rule as follows:

EXAMPLES:

```
sage: A3=WeylCharacterRing("A3",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: [A3(fw).branch(A2,rule="levi") for fw in A3.fundamental_weights()]
[A2(0,0) + A2(1,0), A2(0,1) + A2(1,0), A2(0,0) + A2(0,1)]
```

In this case the Levi branching rule is the default branching rule so we may omit the specification rule="levi".

If a subgroup is not maximal, you may specify a branching rule by finding a chain of intermediate subgroups. For this purpose, branching rules may be multiplied as in the following example.

EXAMPLES:

```
sage: A4=WeylCharacterRing("A4",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: br=branching_rule("A4","A3")*branching_rule("A3","A2")
sage: A4(1,0,0,0).branch(A2,rule=br)
2*A2(0,0) + A2(1,0)
```

You may try omitting the rule if it is "obvious". Default rules are provided for the following cases:

$$A_{2s} \Rightarrow B_s,$$
$$A_{2s-1} \Rightarrow C_s,$$
$$A_{2*s-1} \Rightarrow D_s.$$

The above default rules correspond to embedding the group $SO(2s+1)$, $Sp(2s)$ or $SO(2s)$ into the corresponding general or special linear group by the standard representation. Default rules are also specified for the

following cases:

$$B_{s+1} \Rightarrow D_s,$$
$$D_s \Rightarrow B_s.$$

These correspond to the embedding of $O(n)$ into $O(n+1)$ where $n = 2s$ or $2s+1$. Finally, the branching rule for the embedding of a Levi subgroup is also implemented as a default rule.

EXAMPLES:

```
sage: A1 = WeylCharacterRing("A1", style="coroots")
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: D4 = WeylCharacterRing("D4", style="coroots")
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: B4 = WeylCharacterRing("B4", style="coroots")
sage: A6 = WeylCharacterRing("A6", style="coroots")
sage: A7 = WeylCharacterRing("A7", style="coroots")
sage: def try_default_rule(R,S): return [R(f).branch(S) for f in R.fundamental_weights()]
sage: try_default_rule(A2,A1)
[A1(0) + A1(1), A1(0) + A1(1)]
sage: try_default_rule(D4,B3)
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(0,1,0), B3(0,0,1), B3(0,0,1)]
sage: try_default_rule(B4,D4)
[D4(0,0,0,0) + D4(1,0,0,0), D4(1,0,0,0) + D4(0,1,0,0),
D4(0,1,0,0) + D4(0,0,1,1), D4(0,0,1,0) + D4(0,0,0,1)]
sage: try_default_rule(A7,D4)
[D4(1,0,0,0), D4(0,1,0,0), D4(0,0,1,1), D4(0,0,2,0) + D4(0,0,0,2),
D4(0,0,1,1),
D4(0,1,0,0),
D4(1,0,0,0)]
sage: try_default_rule(A6,B3)
[B3(1,0,0), B3(0,1,0), B3(0,0,2), B3(0,0,2), B3(0,1,0), B3(1,0,0)]
```

If a default rule is not known, you may cue Sage as to what the Lie group embedding is by supplying a rule from the list of predefined rules. We will treat these next.

Levi Type

These can be read off from the Dynkin diagram. If removing a node from the Dynkin diagram produces another Dynkin diagram, there is a branching rule. A Levi subgroup may or may not be maximal. If it is maximal, there may or may not be a built-in branching rule for but you may obtain the Levi branching rule by first branching to

a suitable maximal subgroup. For these rules use the option `rule="levi"`:

$$
\begin{aligned}
A_r &\Rightarrow A_{r-1} \\
B_r &\Rightarrow A_{r-1} \\
B_r &\Rightarrow B_{r-1} \\
C_r &\Rightarrow A_{r-1} \\
C_r &\Rightarrow C_{r-1} \\
D_r &\Rightarrow A_{r-1} \\
D_r &\Rightarrow D_{r-1} \\
E_r &\Rightarrow A_{r-1} \quad r = 7, 8 \\
E_r &\Rightarrow D_{r-1} \quad r = 6, 7, 8 \\
E_r &\Rightarrow E_{r-1} \\
F_4 &\Rightarrow B_3 \\
F_4 &\Rightarrow C_3 \\
G_2 &\Rightarrow A_1 (\text{short root})
\end{aligned}
$$

Not all Levi subgroups are maximal subgroups. If the Levi is not maximal there may or may not be a pre-programmed `rule="levi"` for it. If there is not, the branching rule may still be obtained by going through an intermediate subgroup that is maximal using rule="extended". Thus the other Levi branching rule from $G_2 \Rightarrow A_1$ corresponding to the long root is available by first branching $G_2 \Rightarrow A_2$ then $A_2 \Rightarrow A_1$. Similarly the branching rules to the Levi subgroup:

$$E_r \Rightarrow A_{r-1} \quad r = 6, 7, 8$$

may be obtained by first branching $E_6 \Rightarrow A_5 \times A_1$, $E_7 \Rightarrow A_7$ or $E_8 \Rightarrow A_8$.

EXAMPLES:

```
sage: A1 = WeylCharacterRing("A1")
sage: A2 = WeylCharacterRing("A2")
sage: A3 = WeylCharacterRing("A3")
sage: A4 = WeylCharacterRing("A4")
sage: A5 = WeylCharacterRing("A5")
sage: B2 = WeylCharacterRing("B2")
sage: B3 = WeylCharacterRing("B3")
sage: B4 = WeylCharacterRing("B4")
sage: C2 = WeylCharacterRing("C2")
sage: C3 = WeylCharacterRing("C3")
sage: D3 = WeylCharacterRing("D3")
sage: D4 = WeylCharacterRing("D4")
sage: G2 = WeylCharacterRing("G2")
sage: F4 = WeylCharacterRing("F4",style="coroots")
sage: E6=WeylCharacterRing("E6",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: D5=WeylCharacterRing("D5",style="coroots")
sage: D6=WeylCharacterRing("D6",style="coroots")
sage: [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```

The last example must be understood as follows. The representation of B_3 being branched is spin, which is not a representation of $SO(7)$ but of its double cover $\mathrm{spin}(7)$. The group A_2 is really GL(3) and the double cover of $SO(7)$ induces a cover of $GL(3)$ that is trivial over $SL(3)$ but not over the center of $GL(3)$. The weight lattice for this $GL(3)$ consists of triples (a, b, c) of half integers such that $a - b$ and $b - c$ are in $\mathbf{Z}$, and this is reflected in the last decomposition.

```
sage: [C3(w).branch(A2,rule="levi") for w in C3.fundamental_weights()]
[A2(1,0,0) + A2(0,0,-1),
A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1),
A2(-1,-1,-1) + A2(1,-1,-1) + A2(1,1,-1) + A2(1,1,1)]
sage: [D4(w).branch(A3,rule="levi") for w in D4.fundamental_weights()]
[A3(1,0,0,0) + A3(0,0,0,-1),
A3(0,0,0,0) + A3(1,1,0,0) + A3(1,0,0,-1) + A3(0,0,-1,-1),

A1xB1(1,1) + 2*A1xB1(0,1)]
```

Automorphic Type

If the Dynkin diagram has a symmetry, then there is an automorphism that is a special case of a branching rule. There is also an exotic "triality" automorphism of D_4 having order 3. Use `rule="automorphic"` (or for D_4 `rule="triality"`):

$$A_r \Rightarrow A_r$$
$$D_r \Rightarrow D_r$$
$$E_6 \Rightarrow E_6$$

EXAMPLES:

```
sage: [A3(chi).branch(A3,rule="automorphic") for chi in A3.fundamental_weights()]
[A3(0,0,0,-1), A3(0,0,-1,-1), A3(0,-1,-1,-1)]
sage: [D4(chi).branch(D4,rule="automorphic") for chi in D4.fundamental_weights()]
[D4(1,0,0,0), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2)]
```

Here is an example with D_4 triality:

```
sage: [D4(chi).branch(D4,rule="triality") for chi in D4.fundamental_weights()]
[D4(1/2,1/2,1/2,-1/2), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1,0,0,0)]
```

Symmetric Type

Related to the automorphic type, when G admits an outer automorphism (usually of degree 2) we may consider the branching rule to the isotropy subgroup H. Outer automorphisms correspond to symmetries of the Dynkin diagram. For such isotropy subgroups use `rule="symmetric"`. We may thus obtain the following branching rules.

$$A_{2r} \Rightarrow B_r$$
$$A_{2r-1} \Rightarrow C_r$$
$$A_{2r-1} \Rightarrow D_r$$
$$D_r \Rightarrow B_{r-1}$$
$$E_6 \Rightarrow F_4$$
$$E_6 \Rightarrow C_4$$
$$D_4 \Rightarrow G_2$$

The last branching rule, $D_4 \Rightarrow G_2$ is not to a maximal subgroup since $D_4 \Rightarrow B_3 \Rightarrow G_2$, but it is included for convenience.

In some cases, two outer automorphisms that differ by an inner automorphism may have different fixed subgroups. Thus, while the Dynkin diagram of E_6 has a single involutory automorphism, there are two involutions of the group (differing by an inner automorphism) with fixed subgroups F_4 and C_4. Similarly $SL(2r)$, of Cartan type A_{2r-1}, has subgroups $SO(2r)$ and $Sp(2r)$, both fixed subgroups of outer automorphisms that differ from each other by an inner automorphism.

In many cases the Dynkin diagram of H can be obtained by folding the Dynkin diagram of G.

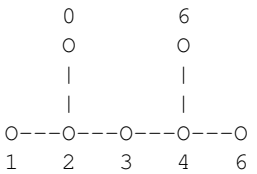
EXAMPLES:

```
sage: [w.branch(B2,rule="symmetric") for w in [A4(1,0,0,0,0),A4(1,1,0,0,0),A4(1,1,1,0,0),A4(2,0,
[B2(1,0), B2(1,1), B2(1,1), B2(0,0) + B2(2,0)]
sage: [A5(w).branch(C3,rule="symmetric") for w in A5.fundamental_weights()]
[C3(1,0,0), C3(0,0,0) + C3(1,1,0), C3(1,0,0) + C3(1,1,1), C3(0,0,0) + C3(1,1,0), C3(1,0,0)]
sage: [A5(w).branch(D3,rule="symmetric") for w in A5.fundamental_weights()]
[D3(1,0,0), D3(1,1,0), D3(1,1,-1) + D3(1,1,1), D3(1,1,0), D3(1,0,0)]
sage: [D4(x).branch(B3,rule="symmetric") for x in D4.fundamental_weights()]
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(1,1,0), B3(1/2,1/2,1/2), B3(1/2,1/2,1/2)]
sage: [D4(x).branch(G2,rule="symmetric") for x in D4.fundamental_weights()]
[G2(0,0,0) + G2(1,0,-1), 2*G2(1,0,-1) + G2(2,-1,-1), G2(0,0,0) + G2(1,0,-1), G2(0,0,0) + G2(1,0,
sage: [E6(fw).branch(F4,rule="symmetric") for fw in E6.fundamental_weights()] # long time (4s)
[F4(0,0,0,0) + F4(0,0,0,1),
 F4(0,0,0,1) + F4(1,0,0,0),
 F4(0,0,0,1) + F4(1,0,0,0) + F4(0,0,1,0),
 F4(1,0,0,0) + 2*F4(0,0,1,0) + F4(1,0,0,1) + F4(0,1,0,0),
 F4(0,0,0,1) + F4(1,0,0,0) + F4(0,0,1,0),
 F4(0,0,0,0) + F4(0,0,0,1)]
sage: E6=WeylCharacterRing("E6",style="coroots")
sage: C4=WeylCharacterRing("C4",style="coroots")
sage: chi = E6(1,0,0,0,0,0); chi.degree()
27
sage: chi.branch(C4,rule="symmetric")
C4(0,1,0,0)
```

Extended Type

If removing a node from the extended Dynkin diagram results in a Dynkin diagram, then there is a branching rule. Use `rule="extended"` for these. We will also use this classification for some rules that are not of this type, mainly involving type B, such as $D_6 \Rightarrow B_3 \times B_3$.

Here is the extended Dynkin diagram for D_6:



Removing the node 3 results in an embedding $D_3 \times D_3 \Rightarrow D_6$. This corresponds to the embedding $SO(6) \times SO(6) \Rightarrow SO(12)$, and is of extended type. On the other hand the embedding $SO(5) \times SO(7) \Rightarrow SO(12)$ (e.g. $B_2 \times B_3 \Rightarrow D_6$) cannot be explained this way but for uniformity is implemented under `rule="extended"`.

The following rules are implemented as special cases of `rule="extended"`:

$$E_6 \Rightarrow A_5 \times A_1, A_2 \times A_2 \times A_2$$
$$E_7 \Rightarrow A_7, D_6 \times A_1, A_3 \times A_3 \times A_1$$
$$E_8 \Rightarrow A_8, D_8, E_7 \times A_1, A_4 \times A_4, D_5 \times A_3, E_6 \times A_2$$
$$F_4 \Rightarrow B_4, C_3 \times A_1, A_2 \times A_2, A_3 \times A_1$$
$$G_2 \Rightarrow A_1 \times A_1$$

Note that E_8 has only a limited number of representations of reasonably low degree.

EXAMPLES:

```
sage: [B3(x).branch(D3,rule="extended") for x in B3.fundamental_weights()]
[D3(0,0,0) + D3(1,0,0),
 D3(1,0,0) + D3(1,1,0),
 D3(1/2,1/2,-1/2) + D3(1/2,1/2,1/2)]
sage: [G2(w).branch(A2, rule="extended") for w in G2.fundamental_weights()]

 [D2xD2(1,1,0,0) + D2xD2(0,0,1,1),
 D2xD2(2,0,0,0) + D2xD2(0,2,0,0) + D2xD2(1,1,1,1) + D2xD2(0,0,2,0) + D2xD2(0,0,0,2),
 D2xD2(1,0,0,1) + D2xD2(0,1,1,0),
 D2xD2(1,0,1,0) + D2xD2(0,1,0,1)]
```

Orthogonal Sum

Using `rule="orthogonal_sum"`, for $n = a + b + c + \cdots$, you can get any branching rule

$$SO(n) \Rightarrow SO(a) \times SO(b) \times SO(c) \times \cdots,$$
$$Sp(2n) \Rightarrow Sp(2a) \times Sp(2b) \times Sp(2c)x \times \cdots,$$

where $O(a)$ is type D_r for $a = 2r$ or B_r for $a = 2r + 1$ and $Sp(2r)$ is type C_r. In some cases these are also of extended type, as in the case $D_3 \times D_3 \Rightarrow D_6$ discussed above. But in other cases, for example $B_3 \times B_3 \Rightarrow D_7$, they are not of extended type.

Tensor

There are branching rules:

$$\begin{aligned} A_{rs-1} &\Rightarrow A_{r-1} \times A_{s-1}, \\ B_{2rs+r+s} &\Rightarrow B_r \times B_s, \\ D_{2rs+s} &\Rightarrow B_r \times D_s, \\ D_{2rs} &\Rightarrow D_r \times D_s, \\ D_{2rs} &\Rightarrow C_r \times C_s, \\ C_{2rs+s} &\Rightarrow B_r \times C_s, \\ C_{2rs} &\Rightarrow C_r \times D_s. \end{aligned}$$

corresponding to the tensor product homomorphism. For type A, the homomorphism is $GL(r) \times GL(s) \Rightarrow GL(rs)$. For the classical types, the relevant fact is that if V, W are orthogonal or symplectic spaces, that is, spaces endowed with symmetric or skew-symmetric bilinear forms, then $V \otimes W$ is also an orthogonal space (if V and W are both orthogonal or both symplectic) or symplectic (if one of V and W is orthogonal and the other symplectic).

The corresponding branching rules are obtained using `rule="tensor"`.

EXAMPLES:

```
sage: A5=WeylCharacterRing("A5", style="coroots")
sage: A2xA1=WeylCharacterRing("A2xA1", style="coroots")
sage: [A5(hwv).branch(A2xA1, rule="tensor") for hwv in A5.fundamental_weights()]
[A2xA1(1,0,1),
A2xA1(0,1,2) + A2xA1(2,0,0),
A2xA1(1,1,1) + A2xA1(0,0,3),
A2xA1(1,0,2) + A2xA1(0,2,0),
A2xA1(0,1,1)]
```

```
sage: B4=WeylCharacterRing("B4",style="coroots")
sage: B1xB1=WeylCharacterRing("B1xB1",style="coroots")
sage: [B4(f).branch(B1xB1,rule="tensor") for f in B4.fundamental_weights()]
[B1xB1(2,2),
B1xB1(2,0) + B1xB1(2,4) + B1xB1(4,2) + B1xB1(0,2),
B1xB1(2,0) + B1xB1(2,2) + B1xB1(2,4) + B1xB1(4,2) + B1xB1(4,4) + B1xB1(6,0) + B1xB1(0,2) + B1xB1
B1xB1(1,3) + B1xB1(3,1)]
sage: D4=WeylCharacterRing("D4",style="coroots")
sage: C2xC1=WeylCharacterRing("C2xC1",style="coroots")
sage: [D4(f).branch(C2xC1,rule="tensor") for f in D4.fundamental_weights()]
[C2xC1(1,0,1),
C2xC1(0,1,2) + C2xC1(2,0,0) + C2xC1(0,0,2),
C2xC1(1,0,1),
C2xC1(0,1,0) + C2xC1(0,0,2)]
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: B1xC1=WeylCharacterRing("B1xC1",style="coroots")
sage: [C3(f).branch(B1xC1,rule="tensor") for f in C3.fundamental_weights()]
[B1xC1(2,1), B1xC1(2,2) + B1xC1(4,0), B1xC1(4,1) + B1xC1(0,3)]
```

Symmetric Power

The k-th symmetric and exterior power homomorphisms map

$$GL(n) \Rightarrow GL\left(\binom{n+k-1}{k}\right) \times GL\left(\binom{n}{k}\right).$$

The corresponding branching rules are not implemented but a special case is. The k-th symmetric power homomorphism $SL(2) \Rightarrow GL(k+1)$ has its image inside of $SO(2r+1)$ if $k = 2r$ and inside of $Sp(2r)$ if $k = 2r-1$. Hence there are branching rules:

$$B_r \Rightarrow A_1$$
$$C_r \Rightarrow A_1$$

and these may be obtained using the rule "symmetric_power".

EXAMPLES:

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: B3=WeylCharacterRing("B3",style="coroots")
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: [B3(fw).branch(A1,rule="symmetric_power") for fw in B3.fundamental_weights()]
[A1(6), A1(2) + A1(6) + A1(10), A1(0) + A1(6)]
sage: [C3(fw).branch(A1,rule="symmetric_power") for fw in C3.fundamental_weights()]
[A1(5), A1(4) + A1(8), A1(3) + A1(9)]
```

Miscellaneous

Use `rule="miscellaneous"` for the following embeddings of maximal subgroups, all involving exceptional groups.

$$
\begin{aligned}
B_3 &\Rightarrow G_2,\\
E_6 &\Rightarrow G_2,\\
E_6 &\Rightarrow A_2,\\
F_4 &\Rightarrow G_2 \times A_1,\\
E_6 &\Rightarrow G_2 \times A_2,\\
E_7 &\Rightarrow G_2 \times C_3,\\
E_7 &\Rightarrow F_4 \times A_1,\\
E_7 &\Rightarrow A_1 \times A_1,\\
E_7 &\Rightarrow G_2 \times A_1,\\
E_8 &\Rightarrow G_2 \times F_4.\\
E_8 &\Rightarrow A2 \times A_1.\\
E_8 &\Rightarrow B2.
\end{aligned}
$$

Except for those embeddings available by `rule="extended"`, these are the only embeddings of these groups as maximal subgroups. There may be other embeddings besides these. For example, there are other more obvious embeddings of A_2 and G_2 into E_6. However the embeddings in this table are characterized as embeddings as maximal subgroups. Regarding the embeddings of A_2 and G_2 in E_6, the embeddings in question may be characterized by the condition that the 27-dimensional representations of E_6 restrict irreducibly to A_2 or G_2. Since G_2 has a subgroup isomorphic to A_2, it is worth mentioning that the composite branching rules:

```
branching_rule("E6","G2","miscellaneous")*branching_rule("G2","A2","extended")
branching_rule("E6","A2","miscellaneous")
```

are distinct.

These embeddings are described more completely (with references to the literature) in the thematic tutorial at:

http://www.sagemath.org/doc/thematic_tutorials/lie.html

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2")
sage: [fw1, fw2, fw3] = B3.fundamental_weights()
sage: B3(fw1+fw3).branch(G2, rule="miscellaneous")
G2(1,0,-1) + G2(2,-1,-1) + G2(2,0,-2)
sage: E6 = WeylCharacterRing("E6",style="coroots")
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: E6(1,0,0,0,0,0).branch(G2,"miscellaneous")
G2(2,0)
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: E6(1,0,0,0,0,0).branch(A2,rule="miscellaneous")
A2(2,2)
sage: E6(0,1,0,0,0,0).branch(A2,rule="miscellaneous")
A2(1,1) + A2(1,4) + A2(4,1)
sage: E6(0,0,0,0,0,2).branch(G2,"miscellaneous") # long time (0.59s)
G2(0,0) + G2(2,0) + G2(1,1) + G2(0,2) + G2(4,0)
sage: F4=WeylCharacterRing("F4",style="coroots")
sage: G2xA1=WeylCharacterRing("G2xA1",style="coroots")
sage: F4(0,0,1,0).branch(G2xA1,rule="miscellaneous")
G2xA1(1,0,0) + G2xA1(1,0,2) + G2xA1(1,0,4) + G2xA1(1,0,6) + G2xA1(0,1,4) + G2xA1(2,0,2) + G2xA1(
sage: E6 = WeylCharacterRing("E6",style="coroots")
```

```
sage: A2xG2 = WeylCharacterRing("A2xG2",style="coroots")
sage: E6(1,0,0,0,0,0).branch(A2xG2,rule="miscellaneous")
A2xG2(0,1,1,0) + A2xG2(2,0,0,0)
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: G2xC3=WeylCharacterRing("G2xC3",style="coroots")
sage: E7(0,1,0,0,0,0,0).branch(G2xC3,rule="miscellaneous") # long time (1.84s)
G2xC3(1,0,1,0,0) + G2xC3(1,0,1,1,0) + G2xC3(0,1,0,0,1) + G2xC3(2,0,1,0,0) + G2xC3(0,0,1,1,0)
sage: F4xA1=WeylCharacterRing("F4xA1",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(F4xA1,"miscellaneous")
F4xA1(0,0,0,1,1) + F4xA1(0,0,0,0,3)
sage: A1xA1=WeylCharacterRing("A1xA1",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(A1xA1,rule="miscellaneous")
A1xA1(2,5) + A1xA1(4,1) + A1xA1(6,3)
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: E7(0,0,0,0,0,0,1).branch(A2,rule="miscellaneous")
A2(0,6) + A2(6,0)
sage: G2xA1=WeylCharacterRing("G2xA1",style="coroots")
sage: E7(1,0,0,0,0,0,0).branch(G2xA1,rule="miscellaneous")
G2xA1(1,0,4) + G2xA1(0,1,0) + G2xA1(2,0,2) + G2xA1(0,0,2)
sage: E8 = WeylCharacterRing("E8",style="coroots")
sage: G2xF4 = WeylCharacterRing("G2xF4",style="coroots")
sage: E8(0,0,0,0,0,0,0,1).branch(G2xF4,rule="miscellaneous") # long time (0.76s)
G2xF4(1,0,0,0,0,1) + G2xF4(0,1,0,0,0,0) + G2xF4(0,0,1,0,0,0)
sage: E8=WeylCharacterRing("E8",style="coroots")
sage: A1xA2=WeylCharacterRing("A1xA2",style="coroots")
sage: E8(0,0,0,0,0,0,0,1).branch(A1xA2,rule="miscellaneous") # long time (0.76s)
A1xA2(2,0,0) + A1xA2(2,2,2) + A1xA2(4,0,3) + A1xA2(4,3,0) + A1xA2(6,1,1) + A1xA2(0,1,1)
sage: B2=WeylCharacterRing("B2",style="coroots")
sage: E8(0,0,0,0,0,0,0,1).branch(B2,rule="miscellaneous") # long time (0.53s)
B2(0,2) + B2(0,6) + B2(3,2)
```

A1 maximal subgroups of exceptional groups

There are seven cases where the exceptional group G_2, F_4, E_7 or E_8 contains a maximal subgroup of type A_1. These are tabulated in Theorem 1 of Testerman, The construction of the maximal A1's in the exceptional algebraic groups, Proc. Amer. Math. Soc. 116 (1992), no. 3, 635-644. The names of these branching rules are roman numerals referring to the seven cases of her Theorem 1. Use these branching rules as in the following examples.

EXAMPLES:

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: F4=WeylCharacterRing("F4",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: E8=WeylCharacterRing("E8",style="coroots")
sage: [G2(f).branch(A1,rule="i") for f in G2.fundamental_weights()]
[A1(6), A1(2) + A1(10)]
sage: F4(1,0,0,0).branch(A1,rule="ii")
A1(2) + A1(10) + A1(14) + A1(22)
sage: E7(0,0,0,0,0,0,1).branch(A1,rule="iii")
A1(9) + A1(17) + A1(27)
sage: E7(0,0,0,0,0,0,1).branch(A1,rule="iv")
A1(5) + A1(11) + A1(15) + A1(21)
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="v") # long time (0.6s)
A1(2) + A1(14) + A1(22) + A1(26) + A1(34) + A1(38) + A1(46) + A1(58)
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="vi") # long time (0.6s)
```

```
A1(2) + A1(10) + A1(14) + A1(18) + A1(22) + A1(26) + A1(28) + A1(34) + A1(38) + A1(46)
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="vii") # long time (0.6s)
A1(2) + A1(6) + A1(10) + A1(14) + A1(16) + A1(18) + 2*A1(22) + A1(26) + A1(28) + A1(34) + A1(38)
```

Branching Rules From Plethysms

Nearly all branching rules $G \Rightarrow H$ where G is of type A, B, C or D are covered by the preceding rules. The function `branching_rule_from_plethysm()` covers the remaining cases.

This is a general rule that includes any branching rule from types A, B, C, or D as a special case. Thus it could be used in place of the above rules and would give the same results. However it is most useful when branching from G to a maximal subgroup H such that $\mathrm{rank}(H) < \mathrm{rank}(G) - 1$.

We consider a homomorphism $H \Rightarrow G$ where G is one of $SL(r+1)$, $SO(2r+1)$, $Sp(2r)$ or $SO(2r)$. The function `branching_rule_from_plethysm()` produces the corresponding branching rule. The main ingredient is the character χ of the representation of H that is the homomorphism to $GL(r+1)$, $GL(2r+1)$ or $GL(2r)$.

This rule is so powerful that it contains the other rules implemented above as special cases. First let us consider the symmetric fifth power representation of $SL(2)$.

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: chi=A1([5])
sage: chi.degree()
 6
sage: chi.frobenius_schur_indicator()
-1
```

This confirms that the character has degree 6 and is symplectic, so it corresponds to a homomorphism $SL(2) \Rightarrow Sp(6)$, and there is a corresponding branching rule $C_3 \Rightarrow A_1$.

```
sage: C3 = WeylCharacterRing("C3",style="coroots")
sage: sym5rule = branching_rule_from_plethysm(chi,"C3")
sage: [C3(hwv).branch(A1,rule=sym5rule) for hwv in C3.fundamental_weights()]
[A1(5), A1(4) + A1(8), A1(3) + A1(9)]
```

This is identical to the results we would obtain using `rule="symmetric_power"`. The next example gives a branching not available by other standard rules.

```
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: D7 = WeylCharacterRing("D7",style="coroots")
sage: ad=G2(0,1); ad.degree(); ad.frobenius_schur_indicator()
 14
 1
sage: spin = D7(0,0,0,0,0,1,0); spin.degree()
 64
sage: spin.branch(G2, rule=branching_rule_from_plethysm(ad, "D7"))
 G2(1,1)
```

We have confirmed that the adjoint representation of G_2 gives a homomorphism into $SO(14)$, and that the pullback of the one of the two 64 dimensional spin representations to $SO(14)$ is an irreducible representation of G_2.

We do not actually have to create the character or its parent WeylCharacterRing to create the branching rule:

```
sage: b = branching_rule("C7","C3(0,0,1)","plethysm"); b
plethysm (along C3(0,0,1)) branching rule C7 => C3
```

Isomorphic Type

Although not usually referred to as a branching rule, the effects of the accidental isomorphisms may be handled using `rule="isomorphic"`:

$$B_2 \Rightarrow C_2$$
$$C_2 \Rightarrow B_2$$
$$A_3 \Rightarrow D_3$$
$$D_3 \Rightarrow A_3$$
$$D_2 \Rightarrow A_1 \Rightarrow A_1$$
$$B_1 \Rightarrow A_1$$
$$C_1 \Rightarrow A_1$$

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2")
sage: C2 = WeylCharacterRing("C2")
sage: [B2(x).branch(C2, rule="isomorphic") for x in B2.fundamental_weights()]
[C2(1,1), C2(1,0)]
sage: [C2(x).branch(B2, rule="isomorphic") for x in C2.fundamental_weights()]
[B2(1/2,1/2), B2(1,0)]
sage: D3 = WeylCharacterRing("D3")
sage: A3 = WeylCharacterRing("A3")
sage: [A3(x).branch(D3,rule="isomorphic") for x in A3.fundamental_weights()]
[D3(1/2,1/2,1/2), D3(1,0,0), D3(1/2,1/2,-1/2)]
sage: [D3(x).branch(A3,rule="isomorphic") for x in D3.fundamental_weights()]
[A3(1/2,1/2,-1/2,-1/2), A3(1/4,1/4,1/4,-3/4), A3(3/4,-1/4,-1/4,-1/4)]
```

Here $A_3(x,y,z,w)$ can be understood as a representation of $SL(4)$. The weights x,y,z,w and $x+t,y+t,z+t,w+t$ represent the same representation of $SL(4)$ - though not of $GL(4)$ - since $A_3(x+t,y+t,z+t,w+t)$ is the same as $A_3(x,y,z,w)$ tensored with $\det^t$. So as a representation of $SL(4)$, `A3(1/4,1/4,1/4,-3/4)` is the same as `A3(1,1,1,0)`. The exterior square representation $SL(4) \Rightarrow GL(6)$ admits an invariant symmetric bilinear form, so is a representation $SL(4) \Rightarrow SO(6)$ that lifts to an isomorphism $SL(4) \Rightarrow \mathrm{Spin}(6)$. Conversely, there are two isomorphisms $SO(6) \Rightarrow SL(4)$, of which we've selected one.

In cases like this you might prefer `style="coroots"`:

```
sage: A3 = WeylCharacterRing("A3",style="coroots")
sage: D3 = WeylCharacterRing("D3",style="coroots")
sage: [D3(fw) for fw in D3.fundamental_weights()]
[D3(1,0,0), D3(0,1,0), D3(0,0,1)]
sage: [D3(fw).branch(A3,rule="isomorphic") for fw in D3.fundamental_weights()]
[A3(0,1,0), A3(0,0,1), A3(1,0,0)]
sage: D2 = WeylCharacterRing("D2", style="coroots")
sage: A1xA1 = WeylCharacterRing("A1xA1", style="coroots")
sage: [D2(fw).branch(A1xA1,rule="isomorphic") for fw in D2.fundamental_weights()]
[A1xA1(1,0), A1xA1(0,1)]
```

Branching From a Reducible WeylCharacterRing

If the Cartan Type of R is reducible, we may project a character onto any of the components, or any combination of components. The rule to project on the first component is specified by the string `"proj1"`, the rule to project on the second component is `"proj2"`. To project on the first and third components, use ``"proj13"` and so on.

EXAMPLES:

```
sage: A2xG2=WeylCharacterRing("A2xG2",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: A2xG2(1,0,1,0).branch(A2,rule="proj1")
7*A2(1,0)
sage: A2xG2(1,0,1,0).branch(G2,rule="proj2")
3*G2(1,0)
sage: A2xA2xG2=WeylCharacterRing("A2xA2xG2",style="coroots")
sage: A2xA2xG2(0,1,1,1,0,1).branch(A2xG2,rule="proj13")
8*A2xG2(0,1,0,1)
```

A more general way of specifying a branching rule from a reducible type is to supply a *list* of rules, one *component rule* for each component type in the root system. In the following example, we branch the fundamental representations of D_4 down to $A_1 \times A_1 \times A_1 \times A_1$ through the intermediate group $D_2 \times D_2$. We use multiplicative notation to compose the branching rules. There is no need to construct the intermediate WeylCharacterRing with type $D_2 \times D_2$.

EXAMPLES:

```
sage: D4 = WeylCharacterRing("D4",style="coroots")
sage: A1xA1xA1xA1 = WeylCharacterRing("A1xA1xA1xA1",style="coroots")
sage: b = branching_rule("D2","A1xA1","isomorphic")
sage: br = branching_rule("D4","D2xD2","extended")*branching_rule("D2xD2","A1xA1xA1xA1",[b,b])
sage: [D4(fw).branch(A1xA1xA1xA1,rule=br) for fw in D4.fundamental_weights()]
[A1xA1xA1xA1(1,1,0,0) + A1xA1xA1xA1(0,0,1,1),
A1xA1xA1xA1(1,1,1,1) + A1xA1xA1xA1(2,0,0,0) + A1xA1xA1xA1(0,2,0,0) + A1xA1xA1xA1(0,0,2,0) + A1xA
A1xA1xA1xA1(1,0,0,1) + A1xA1xA1xA1(0,1,1,0),
A1xA1xA1xA1(1,0,1,0) + A1xA1xA1xA1(0,1,0,1)]
```

In the list of rules to be supplied in branching from a reducible root system, we may use two key words "omit" and "identity". The term "omit" means that we omit one factor, projecting onto the remaining factors. The term "identity" is supplied when the irreducible factor Cartan Types of both the target and the source are the same, and the component branching rule is to be the identity map. For example, we have projection maps from $A_3 \times A_2$ to A_3 and A_2, and the corresponding branching may be accomplished as follows. In this example the same could be accomplished using `rule="proj2"`.

EXAMPLES:

```
sage: A3xA2=WeylCharacterRing("A3xA2",style="coroots")
sage: A3=WeylCharacterRing("A3",style="coroots")
sage: chi = A3xA2(0,1,0,1,0)
sage: chi.branch(A3,rule=["identity","omit"])
3*A3(0,1,0)
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: chi.branch(A2,rule=["omit","identity"])
6*A2(1,0)
```

Yet another way of branching from a reducible root system with repeated Cartan types is to embed along the diagonal. The branching rule is equivalent to the tensor product, as the example shows:

```
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2xG2=WeylCharacterRing("G2xG2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2xG2(1,0,0,1).branch(G2,rule="diagonal")
G2(1,0) + G2(2,0) + G2(1,1)
sage: G2xG2(1,0,0,1).branch(G2,rule="diagonal") == G2(1,0)*G2(0,1)
True
```

Writing Your Own (Branching) Rules

Suppose you want to branch from a group G to a subgroup H. Arrange the embedding so that a Cartan subalgebra U of H is contained in a Cartan subalgebra T of G. There is thus a mapping from the weight spaces $\mathrm{Lie}(T)^* \Rightarrow \mathrm{Lie}(U)^*$. Two embeddings will produce identical branching rules if they differ by an element of the Weyl group of H.

The *rule* is this map $\mathrm{Lie}(T)^*$, which is `G.space()`, to $\mathrm{Lie}(U)^*$, which is `H.space()`, which you may implement as a function. As an example, let us consider how to implement the branching rule $A_3 \Rightarrow C_2$. Here $H = C_2 = Sp(4)$ embedded as a subgroup in $A_3 = GL(4)$. The Cartan subalgebra U consists of diagonal matrices with eigenvalues $u_1, u_2, -u_2, -u_1$. The `C2.space()` is the two dimensional vector spaces consisting of the linear functionals u_1 and u_2 on U. On the other hand $\mathrm{Lie}(T)$ is $\mathbf{R}^4$. A convenient way to see the restriction is to think of it as the adjoint of the map $(u_1, u_2) \mapsto (u_1, u_2, -u_2, -u_1)$, that is, $(x_0, x_1, x_2, x_3) \Rightarrow (x_0 - x_3, x_1 - x_2)$. Hence we may encode the rule as follows:

```
def rule(x):
    return [x[0]-x[3],x[1]-x[2]]
```

or simply:

```
rule = lambda x : [x[0]-x[3],x[1]-x[2]]
```

We may now make and use the branching rule as follows.

EXAMPLES:

```
sage: br = BranchingRule("A3", "C2", lambda x : [x[0]-x[3],x[1]-x[2]], "homemade"); br
homemade branching rule A3 => C2
sage: [A3,C2]=[WeylCharacterRing(x,style="coroots") for x in ["A3","C2"]]
sage: A3(0,1,0).branch(C2,rule=br)
C2(0,0) + C2(0,1)
```

sage.combinat.root_system.branching_rules.**branching_rule**(*Rtype*, *Stype*, *rule='default'*)

Creates a branching rule.

INPUT:

- `R` – the Weyl Character Ring of G
- `S` – the Weyl Character Ring of H
- `rule` – a string describing the branching rule as a map from the weight space of S to the weight space of R.

If the rule parameter is omitted, in some cases, a default rule is supplied. See `branch_weyl_character()`.

EXAMPLES:

```
sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]
```

sage.combinat.root_system.branching_rules.**branching_rule_from_plethysm**(*chi*, *cartan_type*, *return_matrix=False*)

Create the branching rule of a plethysm.

INPUT:

- chi – the character of an irreducible representation π of a group G
- cartan_type – a classical Cartan type (A,'B','C' or D).

It is assumed that the image of the irreducible representation pi naturally has its image in the group G.

Returns a branching rule for this plethysm.

EXAMPLES:

The adjoint representation $SL(3) \to GL(8)$ factors through $SO(8)$. The branching rule in question will describe how representations of $SO(8)$ composed with this homomorphism decompose into irreducible characters of $SL(3)$:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: ad = A2.adjoint_representation(); ad
A2(1,1)
sage: ad.degree()
8
sage: ad.frobenius_schur_indicator()
1
```

This confirms that ad has degree 8 and is orthogonal, hence factors through $SO(8)$ which is type D_4:

```
sage: br = branching_rule_from_plethysm(ad,"D4")
sage: D4 = WeylCharacterRing("D4")
sage: [D4(f).branch(A2,rule = br) for f in D4.fundamental_weights()]
[A2(1,1), A2(0,3) + A2(1,1) + A2(3,0), A2(1,1), A2(1,1)]
```

sage.combinat.root_system.branching_rules.**get_branching_rule**(*Rtype*, *Stype*, *rule='default'*)

Creates a branching rule.

INPUT:

- R – the Weyl Character Ring of G
- S – the Weyl Character Ring of H
- rule – a string describing the branching rule as a map from the weight space of S to the weight space of R.

If the rule parameter is omitted, in some cases, a default rule is supplied. See branch_weyl_character().

EXAMPLES:

```
sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]
```

sage.combinat.root_system.branching_rules.**maximal_subgroups**(*ct*, *mode='print_rules'*)

Given a classical Cartan type (of rank less than or equal to 8) this prints the Cartan types of maximal subgroups, with a method of obtaining the branching rule. The string to the right of the colon in the output is a command to create a branching rule.

INPUT:

- ct – a classical irreducible Cartan type

Returns a list of maximal subgroups of ct.

EXAMPLES:

```
sage: from sage.combinat.root_system.branching_rules import maximal_subgroups
sage: maximal_subgroups("D4")
B3:branching_rule("D4","B3","symmetric")
A2:branching_rule("D4","A2(1,1)","plethysm")
A1xC2:branching_rule("D4","C1xC2","tensor")*branching_rule("C1xC2","A1xC2",[branching_rule("C1",
A1xA1xA1xA1:branching_rule("D4","D2xD2","orthogonal_sum")*branching_rule("D2xD2","A1xA1xA1xA1",[
```

5.1.196 Cartan matrices

AUTHORS:

- Travis Scrimshaw (2012-04-22): Nicolas M. Thiery moved matrix creation to `CartanType` to prepare `cartan_matrix()` for deprecation.
- Christian Stump, Travis Scrimshaw (2013-04-13): Created `CartanMatrix`.

class `sage.combinat.root_system.cartan_matrix.`**`CartanMatrix`**

Bases: `sage.matrix.matrix_integer_sparse.Matrix_integer_sparse`, `sage.combinat.root_system.cartan_type.CartanType_abstract`

A (generalized) Cartan matrix.

A matrix $A = (a_{ij})_{i,j \in I}$ for some index set I is a generalized Cartan matrix if it satisfies the following properties:

- $a_{ii} = 2$ for all i,
- $a_{ij} \leq 0$ for all $i \neq j$,
- $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

Additionally some reference assume that a Cartan matrix is *symmetrizable* (see `is_symmetrizable()`). However following Kac, we do not make that assumption here.

INPUT:

Can be anything which is accepted by `CartanType` or a matrix.

If given a matrix, one can also use the keyword `cartan_type` when giving a matrix to explicitly state the type. Otherwise this will try to check the input matrix against possible standard types of Cartan matrices. To disable this check, use the keyword `cartan_type_check = False`.

EXAMPLES:

```
sage: CartanMatrix(['A', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
sage: CartanMatrix(['B', 6])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -1  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0  0  0 -2  2]
sage: CartanMatrix(['C', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -2]
[ 0  0 -1  2]
```

```
sage: CartanMatrix(['D', 6])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -1  2 -1 -1]
[ 0  0  0 -1  2  0]
[ 0  0  0 -1  0  2]
sage: CartanMatrix(['E',6])
[ 2  0 -1  0  0  0]
[ 0  2  0 -1  0  0]
[-1  0  2 -1  0  0]
[ 0 -1 -1  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0  0  0 -1  2]
sage: CartanMatrix(['E',7])
[ 2  0 -1  0  0  0  0]
[ 0  2  0 -1  0  0  0]
[-1  0  2 -1  0  0  0]
[ 0 -1 -1  2 -1  0  0]
[ 0  0  0 -1  2 -1  0]
[ 0  0  0  0 -1  2 -1]
[ 0  0  0  0  0 -1  2]
sage: CartanMatrix(['E', 8])
[ 2  0 -1  0  0  0  0  0]
[ 0  2  0 -1  0  0  0  0]
[-1  0  2 -1  0  0  0  0]
[ 0 -1 -1  2 -1  0  0  0]
[ 0  0  0 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0 -1  2 -1]
[ 0  0  0  0  0  0 -1  2]
sage: CartanMatrix(['F', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -2  2 -1]
[ 0  0 -1  2]
```

This is different from MuPAD-Combinat, due to different node convention?

```
sage: CartanMatrix(['G', 2])
[ 2 -3]
[-1  2]
sage: CartanMatrix(['A',1,1])
[ 2 -2]
[-2  2]
sage: CartanMatrix(['A', 3, 1])
[ 2 -1  0 -1]
[-1  2 -1  0]
[ 0 -1  2 -1]
[-1  0 -1  2]
sage: CartanMatrix(['B', 3, 1])
[ 2  0 -1  0]
[ 0  2 -1  0]
[-1 -1  2 -1]
[ 0  0 -2  2]
sage: CartanMatrix(['C', 3, 1])
[ 2 -1  0  0]
[-2  2 -1  0]
[ 0 -1  2 -2]
```

```
[ 0  0 -1  2]
sage: CartanMatrix(['D', 4, 1])
[ 2  0 -1  0  0]
[ 0  2 -1  0  0]
[-1 -1  2 -1 -1]
[ 0  0 -1  2  0]
[ 0  0 -1  0  2]
sage: CartanMatrix(['E', 6, 1])
[ 2  0 -1  0  0  0  0]
[ 0  2  0 -1  0  0  0]
[-1  0  2  0 -1  0  0]
[ 0 -1  0  2 -1  0  0]
[ 0  0 -1 -1  2 -1  0]
[ 0  0  0  0 -1  2 -1]
[ 0  0  0  0  0 -1  2]
sage: CartanMatrix(['E', 7, 1])
[ 2 -1  0  0  0  0  0  0]
[-1  2  0 -1  0  0  0  0]
[ 0  0  2  0 -1  0  0  0]
[ 0 -1  0  2 -1  0  0  0]
[ 0  0 -1 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0 -1  2 -1]
[ 0  0  0  0  0  0 -1  2]
sage: CartanMatrix(['E', 8, 1])
[ 2  0  0  0  0  0  0  0 -1]
[ 0  2  0 -1  0  0  0  0  0]
[ 0  0  2  0 -1  0  0  0  0]
[ 0 -1  0  2 -1  0  0  0  0]
[ 0  0 -1 -1  2 -1  0  0  0]
[ 0  0  0  0 -1  2 -1  0  0]
[ 0  0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0  0 -1  2 -1]
[-1  0  0  0  0  0  0 -1  2]
sage: CartanMatrix(['F', 4, 1])
[ 2 -1  0  0  0]
[-1  2 -1  0  0]
[ 0 -1  2 -1  0]
[ 0  0 -2  2 -1]
[ 0  0  0 -1  2]
sage: CartanMatrix(['G', 2, 1])
[ 2  0 -1]
[ 0  2 -3]
[-1 -1  2]
```

Note: Since this is a matrix, `row()` and `column()` will return the standard row and column respectively. To get the row with the indices as in Dynkin diagrams/Cartan types, use `row_with_indices()` and `column_with_indices()` respectively.

---

cartan_matrix()

Return the Cartan matrix of `self`.

EXAMPLES:

```
sage: CartanMatrix(['C',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

cartan_type()
Return the Cartan type of `self` or `self` if unknown.

EXAMPLES:

```
sage: C = CartanMatrix(['A',4,1])
sage: C.cartan_type()
['A', 4, 1]
```

If the Cartan type is unknown:

```
sage: C = CartanMatrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: C.cartan_type()
[ 2 -1 -2]
[-1  2 -1]
[-2 -1  2]
```

column_with_indices(j)
Return the j^{th} column $(a_{i,j})_i$ of `self` as a container (or iterator) of tuples $(i, a_{i,j})$

EXAMPLES:

```
sage: M = CartanMatrix(['B',4])
sage: [ (i,a) for (i,a) in M.column_with_indices(3) ]
[(3, 2), (2, -1), (4, -2)]
```

dual()
Return the dual Cartan matrix of `self`, which is obtained by taking the transpose.

EXAMPLES:

```
sage: ct = CartanType(['C',3])
sage: M = CartanMatrix(ct); M
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
sage: M.dual()
[ 2 -1  0]
[-1  2 -1]
[ 0 -2  2]
sage: M.dual() == CartanMatrix(ct.dual())
True
sage: M.dual().cartan_type() == ct.dual()
True
```

An example with arbitrary Cartan matrices:

```
sage: cm = CartanMatrix([[2,-5], [-2, 2]]); cm
[ 2 -5]
[-2  2]
sage: cm.dual()
[ 2 -2]
[-5  2]
sage: cm.dual() == CartanMatrix(cm.transpose())
True
sage: cm.dual().dual() == cm
True
```

dynkin_diagram()
Return the Dynkin diagram corresponding to `self`.

EXAMPLES:

```
sage: C = CartanMatrix(['A',2])
sage: C.dynkin_diagram()
O---O
1   2
A2
sage: C = CartanMatrix(['F',4,1])
sage: C.dynkin_diagram()
O---O---O=>=O---O
0   1   2   3   4
F4~
sage: C = CartanMatrix([[2,-4],[-4,2]])
sage: C.dynkin_diagram()
Dynkin diagram of rank 2
```

indecomposable_blocks()

Return a tuple of all indecomposable blocks of `self`.

EXAMPLES:

```
sage: M = CartanMatrix(['A',2])
sage: M.indecomposable_blocks()
(
[ 2 -1]
[-1  2]
)
sage: M = CartanMatrix([['A',2,1],['A',3,1]])
sage: M.indecomposable_blocks()
(
[ 2 -1  0 -1]
[-1  2 -1  0]  [ 2 -1 -1]
[ 0 -1  2 -1]  [-1  2 -1]
[-1  0 -1  2], [-1 -1  2]
)
```

index_set()

Return the index set of `self`.

EXAMPLES:

```
sage: C = CartanMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CartanMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```

is_affine()

Return `True` if `self` is an affine type or `False` otherwise.

A generalized Cartan matrix is affine if all of its indecomposable blocks are either finite (see `is_finite()`) or have zero determinant with all proper principal minors positive.

EXAMPLES:

```
sage: M = CartanMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CartanMatrix(['D',4,1])
sage: M.is_affine()
True
```

```
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_affine()
False
```

is_crystallographic()
Implements `CartanType_abstract.is_crystallographic()`.

A Cartan matrix is crystallographic if it is symmetrizable.

EXAMPLES:

```
sage: CartanMatrix(['F',4]).is_crystallographic()
True
```

is_finite()
Return `True` if `self` is a finite type or `False` otherwise.

A generalized Cartan matrix is finite if the determinant of all its principal submatrices (see `principal_submatrices()`) is positive. Such matrices have a positive definite symmetrized matrix. Note that a finite matrix may consist of multiple blocks of Cartan matrices each having finite Cartan type.

EXAMPLES:

```
sage: M = CartanMatrix(['C',4])
sage: M.is_finite()
True
sage: M = CartanMatrix(['D',4,1])
sage: M.is_finite()
False
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_finite()
False
```

is_hyperbolic(*compact=False*)
Return if `True` if `self` is a (compact) hyperbolic type or `False` otherwise.

An indecomposable generalized Cartan matrix is hyperbolic if it has negative determinant and if any proper connected subdiagram of its Dynkin diagram is of finite or affine type. It is compact hyperbolic if any proper connected subdiagram has finite type.

INPUT:

- `compact` – if `True`, check if matrix is compact hyperbolic

EXAMPLES:

```
sage: M = CartanMatrix([[2,-2,0],[-2,2,-1],[0,-1,2]])
sage: M.is_hyperbolic()
True
sage: M.is_hyperbolic(compact=True)
False
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_hyperbolic()
True
sage: M = CartanMatrix(['C',4])
sage: M.is_hyperbolic()
False
```

is_indecomposable()
Return if `self` is an indecomposable matrix or `False` otherwise.

EXAMPLES:

```
sage: M = CartanMatrix(['A',5])
sage: M.is_indecomposable()
True
sage: M = CartanMatrix([[2,-1,0],[-1,2,0],[0,0,2]])
sage: M.is_indecomposable()
False
```

is_indefinite()

Return if `self` is an indefinite type or `False` otherwise.

EXAMPLES:

```
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_indefinite()
True
sage: M = CartanMatrix("A2")
sage: M.is_indefinite()
False
```

is_lorentzian()

Return `True` if `self` is a Lorentzian type or `False` otherwise.

A generalized Cartan matrix is Lorentzian if it has negative determinant and exactly one negative eigenvalue.

EXAMPLES:

```
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_lorentzian()
True
sage: M = CartanMatrix([[2,-1],[-1,2]])
sage: M.is_lorentzian()
False
```

is_simply_laced()

Implements `CartanType_abstract.is_simply_laced()`.

A Cartan matrix is simply-laced if all non diagonal entries are 0 or -1.

EXAMPLES:

```
sage: cm = CartanMatrix([[2, -1, -1, -1], [-1, 2, -1, -1], [-1, -1, 2, -1], [-1, -1, -1, 2]]
sage: cm.is_simply_laced()
True
```

principal_submatrices(*proper=False*)

Return a list of all principal submatrices of `self`.

INPUT:

- `proper` – if `True`, return only proper submatrices

EXAMPLES:

```
sage: M = CartanMatrix(['A',2])
sage: M.principal_submatrices()
[
              [ 2 -1]
[], [2], [2], [-1  2]
]
sage: M.principal_submatrices(proper=True)
[[], [2], [2]]
```

rank()
Return the rank of `self`.

EXAMPLES:

```
sage: CartanMatrix(['C',3]).rank()
3
sage: CartanMatrix(["A2","B2","F4"]).rank()
8
```

reflection_group(*type='matrix'*)
Return the reflection group corresponding to `self`.

EXAMPLES:

```
sage: C = CartanMatrix(['A',3])
sage: C.reflection_group()
Weyl Group of type ['A', 3] (as a matrix group acting on the root space)
```

relabel(*relabelling*)
Return the relabelled Cartan matrix.

EXAMPLES:

```
sage: CM = CartanMatrix(['C',3])
sage: R = CM.relabel({1:0, 2:4, 3:1}); R
[ 2  0 -1]
[ 0  2 -1]
[-1 -2  2]
sage: R.index_set()
(0, 1, 4)
sage: CM
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

root_space()
Return the root space corresponding to `self`.

EXAMPLES:

```
sage: C = CartanMatrix(['A',3])
sage: C.root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

root_system()
Return the root system corresponding to `self`.

EXAMPLES:

```
sage: C = CartanMatrix(['A',3])
sage: C.root_system()
Root system of type ['A', 3]
```

row_with_indices(*i*)
Return the i^{th} row $(a_{i,j})_j$ of `self` as a container (or iterator) of tuples $(j, a_{i,j})$

EXAMPLES:

```
sage: M = CartanMatrix(['C',4])
sage: [ (i,a) for (i,a) in M.row_with_indices(3) ]
[(3, 2), (2, -1), (4, -2)]
```

subtype(*index_set*)

Return a subtype of `self` given by `index_set`.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of `self` by `index_set`.

EXAMPLES:

```
sage: C = CartanMatrix(['F',4])
sage: S = C.subtype([1,2,3])
sage: S
[ 2 -1  0]
[-1  2 -1]
[ 0 -2  2]
sage: S.index_set()
(1, 2, 3)
```

symmetrized_matrix()

Return the symmetrized matrix of `self` if symmetrizable.

EXAMPLES:

```
sage: cm = CartanMatrix(['B',4,1])
sage: cm.symmetrized_matrix()
[ 4  0 -2  0  0]
[ 0  4 -2  0  0]
[-2 -2  4 -2  0]
[ 0  0 -2  4 -2]
[ 0  0  0 -2  2]
```

symmetrizer()

Return the symmetrizer of `self`.

EXAMPLES:

```
sage: cm = CartanMatrix([[2,-5],[-2,2]])
sage: cm.symmetrizer()
Finite family {0: 2, 1: 5}
```

TESTS:

Check that the symmetrizer computed from the Cartan matrix agrees with the values given by the Cartan type:

```
sage: ct = CartanType(['B',4,1])
sage: ct.symmetrizer()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
sage: ct.cartan_matrix().symmetrizer()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

sage.combinat.root_system.cartan_matrix.**find_cartan_type_from_matrix**(*CM*)

Find a Cartan type by direct comparison of Dynkin diagrams given from the generalized Cartan matrix `CM` and return `None` if not found.

INPUT:

- `CM` – a generalized Cartan matrix

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_matrix import find_cartan_type_from_matrix
sage: CM = CartanMatrix([[2,-1,-1], [-1,2,-1], [-1,-1,2]])
sage: find_cartan_type_from_matrix(CM)
['A', 2, 1]
sage: CM = CartanMatrix([[2,-1,0], [-1,2,-2], [0,-1,2]])
sage: find_cartan_type_from_matrix(CM)
['C', 3] relabelled by {1: 0, 2: 1, 3: 2}
sage: CM = CartanMatrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: find_cartan_type_from_matrix(CM)
```

sage.combinat.root_system.cartan_matrix.**is_generalized_cartan_matrix**(*M*)

Return `True` if `M` is a generalized Cartan matrix. For a definition of a generalized Cartan matrix, see `CartanMatrix`.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_matrix import is_generalized_cartan_matrix
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: is_generalized_cartan_matrix(M)
True
sage: M = matrix([[2,-1,-2], [-1,2,-1], [0,-1,2]])
sage: is_generalized_cartan_matrix(M)
False
sage: M = matrix([[1,-1,-2], [-1,2,-1], [-2,-1,2]])
sage: is_generalized_cartan_matrix(M)
False
```

A non-symmetrizable example:

```
sage: M = matrix([[2,-1,-2], [-1,2,-1], [-1,-1,2]])
sage: is_generalized_cartan_matrix(M)
True
```

5.1.197 Cartan types

Todo

Why does sphinx complain if I use sections here?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. *Cartan types* are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type A_4:

```
sage: T = CartanType(['A', 4])
sage: T
['A', 4]
```

It is the name of the following Dynkin diagram:

```
sage: DynkinDiagram(T)
O---O---O---O
1   2   3   4
A4
```

Note: For convenience, the following shortcuts are available:

```
sage: DynkinDiagram(['A',4])
O---O---O---O
1   2   3   4
A4
sage: DynkinDiagram('A4')
O---O---O---O
1   2   3   4
A4
sage: T.dynkin_diagram()
O---O---O---O
1   2   3   4
A4
```

See DynkinDiagram for how to further manipulate Dynkin diagrams.

From this data (the *Cartan datum*), one can construct the associated root system:

```
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of A_n is the symmetric group S_{n+1}:

```
sage: W = WeylGroup(T)
sage: W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120
```

while the Lie algebra is sl_{n+1}, and the Lie group SL_{n+1} (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

```
sage: C = crystals.Letters(T)
sage: C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]

sage: C = crystals.Tableaux(T, shape=[2])
sage: C
The crystal of tableaux of type ['A', 4] and shape(s) [[2]]
sage: C.cardinality()
15
```

Here is a sample of all the finite irreducible crystallographic Cartan types:

```
sage: CartanType.samples(finite = True, crystallographic = True)
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
 ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2]]
```

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:

```
sage: [latex(ct) for ct in CartanType.samples(crystallographic=True)]
[A_{1}, A_{5}, B_{1}, B_{5}, C_{1}, C_{5}, D_{2}, D_{3}, D_{5},
 E_6, E_7, E_8, F_4, G_2,
 A_{1}^{(1)}, A_{5}^{(1)}, B_{1}^{(1)}, B_{5}^{(1)}, C_{1}^{(1)}, C_{5}^{(1)}, D_{3}^{(1)}, D_{5}^{(1
```

```
 E_6^{(1)}, E_7^{(1)}, E_8^{(1)}, F_4^{(1)}, G_2^{(1)},
 BC_{1}^{(2)}, BC_{5}^{(2)},
 B_{5}^{(1)\vee}, C_{4}^{(1)\vee}, F_4^{(1)\vee}, G_2^{(1)\vee}, BC_{1}^{(2)\vee}, BC_{5}^{(2)\vee}]
sage: view([DynkinDiagram(ct) for ct in CartanType.samples(crystallographic=True)]) # not tested
```

Non-crystallographic Cartan types are also partially supported:

```
sage: CartanType.samples(finite = True, crystallographic = False)
[['I', 5], ['H', 3], ['H', 4]]
```

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. sage.combinat.root_system.type_A). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root_system), and further mathematical properties:

```
sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)
```

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3540426509. For example:

```
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)
    O 4
    |
    |
O---O---O
1   2   3
D4

sage: E6 = CartanType(['E',6])
sage: DynkinDiagram(E6)
        O 2
        |
        |
O---O---O---O---O
1   3   4   5   6
E6
```

Note: The direction of the arrows is the **opposite** (i.e. the transpose) of Bourbaki's convention, but agrees with Kac's.

For example, in type C_2, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2
O=<=O
1   2
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]
```

However Bourbaki would have the Cartan matrix as:

$$\begin{bmatrix} 2 & -1 \\ -2 & 2 \end{bmatrix}.$$

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type E_6 can be obtained via:

```
sage: E6.relabel({1:1,2:6,3:2,4:3,5:4,6:5}).dynkin_diagram()
        O 6
        |
        |
O---O---O---O---O
1   2   3   4   5
E6 relabelled by {1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5}
```

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()
sage: g.add_vertices([1,2,3])
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Then we add a couple edges:

```
sage: g.add_edge(1,2,2)
sage: g.add_edge(1,3)
sage: g.add_edge(2,3)
```

and we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see `cached_method`). In general, a Dynkin diagram should not be modified after having been used.

Warning: this is not checked currently

Todo

add a method `set_mutable()` as, say, for matrices

Here, we can work around this by clearing the cache:

```
sage: delattr(g, 'cartan_matrix')
```

Now we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2  2 -1]
[-1 -1  2]
```

Note that backward edges have been automatically added:

```
sage: g.edges()
[(1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1)]
```

Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```

or using the following short hand notation:

```
sage: CartanType("A2xB2")
A2xB2
sage: CartanType("A2","B2") == CartanType("A2xB2")
True
```

Degenerate cases

When possible, type I_n is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```
sage: CartanType(["I",1])
A1xA1
sage: CartanType(["I",3])
['A', 2]
sage: CartanType(["I",4])
['C', 2]
sage: CartanType(["I",6])
['G', 2]
```

The Dynkin diagrams for types B_1, C_1, D_2, and D_3 are isomorphic to that for A_1, A_1, $A_1 \times A_1$, and A_3, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

```
sage: CartanType(['B',1])
['B', 1]
sage: CartanType(['C',1])
['C', 1]
sage: CartanType(['D',2])
['D', 2]
sage: CartanType(['D',3])
['D', 3]
```

Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):

```
sage: CartanType(["A", 4, 1]).dynkin_diagram()
0
O-----------+
|           |
|           |
O---O---O---O
1   2   3   4
A4~
sage: CartanType(["B", 4, 1]).dynkin_diagram()
    O 0
    |
    |
O---O---O=>=O
1   2   3   4
B4~
```

or dual thereof:

```
sage: CartanType(["B", 4, 1]).dual().dynkin_diagram()
    O 0
    |
    |
O---O---O=<=O
1   2   3   4
B4~*
```

or is of type $\widetilde{BC}_n$ (which yields an irreducible, but nonreduced root system):

```
sage: CartanType(["BC", 4, 2]).dynkin_diagram()
O=<=O---O---O=<=O
0   1   2   3   4
BC4~
```

This includes the two degenerate cases:

```
sage: CartanType(["A", 1, 1]).dynkin_diagram()
O<=>O
0   1
A1~
sage: CartanType(["BC", 1, 2]).dynkin_diagram()
  4
O=<=O
0   1
BC1~
```

For the user convenience, Kac's notations for twisted affine types are automatically translated into the previous ones:

```
sage: CartanType(["A", 9, 2])
['B', 5, 1]^*
sage: CartanType(["A", 9, 2]).dynkin_diagram()
    O 0
    |
    |
```

```
O---O---O---O=<=O
1   2   3   4   5
B5~*
sage: CartanType(["A", 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
0   1   2   3   4   5
BC5~
sage: CartanType(["D", 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
C4~*
sage: CartanType(["D", 4, 3]).dynkin_diagram()
  3
O=>=O---O
2   1   0
G2~* relabelled by {0: 0, 1: 2, 2: 1}
sage: CartanType(["E", 6, 2]).dynkin_diagram()
O---O---O=<=O---O
0   1   2   3   4
F4~*
```

Additionally one can set the notation global option to use Kac's notation:

```
sage: CartanType.global_options['notation'] = 'Kac'
sage: CartanType(["A", 9, 2])
['A', 9, 2]
sage: CartanType(["A", 9, 2]).dynkin_diagram()
    O 0
    |
    |
O---O---O---O=<=O
1   2   3   4   5
A9^2
sage: CartanType(["A", 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
0   1   2   3   4   5
A10^2
sage: CartanType(["D", 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
D5^2
sage: CartanType(["D", 4, 3]).dynkin_diagram()
  3
O=>=O---O
2   1   0
D4^3
sage: CartanType(["E", 6, 2]).dynkin_diagram()
O---O---O=<=O---O
0   1   2   3   4
E6^2
sage: CartanType.global_options['notation'] = 'BC'
```

Todo

Why does sphinx complain if I use sections here?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. *Cartan types* are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type A_4:

```
sage: T = CartanType(['A', 4])
sage: T
['A', 4]
```

It is the name of the following Dynkin diagram:

```
sage: DynkinDiagram(T)
O---O---O---O
1   2   3   4
A4
```

Note: For convenience, the following shortcuts are available:

```
sage: DynkinDiagram(['A',4])
O---O---O---O
1   2   3   4
A4
sage: DynkinDiagram('A4')
O---O---O---O
1   2   3   4
A4
sage: T.dynkin_diagram()
O---O---O---O
1   2   3   4
A4
```

See `DynkinDiagram` for how to further manipulate Dynkin diagrams.

From this data (the *Cartan datum*), one can construct the associated root system:

```
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of A_n is the symmetric group S_{n+1}:

```
sage: W = WeylGroup(T)
sage: W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120
```

while the Lie algebra is sl_{n+1}, and the Lie group SL_{n+1} (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

```
sage: C = crystals.Letters(T)
sage: C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]

sage: C = crystals.Tableaux(T, shape=[2])
```

```
sage: C
The crystal of tableaux of type ['A', 4] and shape(s) [[2]]
sage: C.cardinality()
15
```

Here is a sample of all the finite irreducible crystallographic Cartan types:

```
sage: CartanType.samples(finite = True, crystallographic = True)
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
 ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2]]
```

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:

```
sage: [latex(ct) for ct in CartanType.samples(crystallographic=True)]
[A_{1}, A_{5}, B_{1}, B_{5}, C_{1}, C_{5}, D_{2}, D_{3}, D_{5},
 E_6, E_7, E_8, F_4, G_2,
 A_{1}^{(1)}, A_{5}^{(1)}, B_{1}^{(1)}, B_{5}^{(1)}, C_{1}^{(1)}, C_{5}^{(1)}, D_{3}^{(1)}, D_{5
 E_6^{(1)}, E_7^{(1)}, E_8^{(1)}, F_4^{(1)}, G_2^{(1)},
 BC_{1}^{(2)}, BC_{5}^{(2)},
 B_{5}^{(1)\vee}, C_{4}^{(1)\vee}, F_4^{(1)\vee}, G_2^{(1)\vee}, BC_{1}^{(2)\vee}, BC_{5}^{(2)\v
sage: view([DynkinDiagram(ct) for ct in CartanType.samples(crystallographic=True)]) # not tested
```

Non-crystallographic Cartan types are also partially supported:

```
sage: CartanType.samples(finite = True, crystallographic = False)
[['I', 5], ['H', 3], ['H', 4]]
```

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. `sage.combinat.root_system.type_A`). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root_system), and further mathematical properties:

```
sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)
```

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3540426509. For example:

```
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)
    O 4
    |
    |
O---O---O
1   2   3
D4

sage: E6 = CartanType(['E',6])
sage: DynkinDiagram(E6)
        O 2
        |
        |
O---O---O---O---O
1   3   4   5   6
E6
```

Note: The direction of the arrows is the **opposite** (i.e. the transpose) of Bourbaki's convention, but agrees with Kac's.

For example, in type C_2, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2
O=<=O
1   2
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]
```

However Bourbaki would have the Cartan matrix as:

$$\begin{bmatrix} 2 & -1 \\ -2 & 2 \end{bmatrix}.$$

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type E_6 can be obtained via:

```
sage: E6.relabel({1:1,2:6,3:2,4:3,5:4,6:5}).dynkin_diagram()
        O 6
        |
        |
O---O---O---O---O
1   2   3   4   5
E6 relabelled by {1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5}
```

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()
sage: g.add_vertices([1,2,3])
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Then we add a couple edges:

```
sage: g.add_edge(1,2,2)
sage: g.add_edge(1,3)
sage: g.add_edge(2,3)
```

and we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[2 0 0]
[0 2 0]
[0 0 2]
```

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see `cached_method`). In general, a Dynkin diagram should not be modified after having been used.

Warning: this is not checked currently

Todo

add a method `set_mutable()` as, say, for matrices

Here, we can work around this by clearing the cache:

```
sage: delattr(g, 'cartan_matrix')
```

Now we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2  2 -1]
[-1 -1  2]
```

Note that backward edges have been automatically added:

```
sage: g.edges()
[(1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1)]
```

Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```

or using the following short hand notation:

```
sage: CartanType("A2xB2")
A2xB2
sage: CartanType("A2","B2") == CartanType("A2xB2")
True
```

Degenerate cases

When possible, type I_n is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```
sage: CartanType(["I",1])
A1xA1
sage: CartanType(["I",3])
['A', 2]
sage: CartanType(["I",4])
['C', 2]
sage: CartanType(["I",6])
['G', 2]
```

The Dynkin diagrams for types B_1, C_1, D_2, and D_3 are isomorphic to that for A_1, A_1, $A_1 \times A_1$, and A_3, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families

of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

```
sage: CartanType(['B',1])
['B', 1]
sage: CartanType(['C',1])
['C', 1]
sage: CartanType(['D',2])
['D', 2]
sage: CartanType(['D',3])
['D', 3]
```

Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):

```
sage: CartanType(["A", 4, 1]).dynkin_diagram()
0
O------------+
|            |
|            |
O---O---O---O
1   2   3   4
A4~
sage: CartanType(["B", 4, 1]).dynkin_diagram()
    O 0
    |
    |
O---O---O=>=O
1   2   3   4
B4~
```

or dual thereof:

```
sage: CartanType(["B", 4, 1]).dual().dynkin_diagram()
    O 0
    |
    |
O---O---O=<=O
1   2   3   4
B4~*
```

or is of type $\widetilde{BC}_n$ (which yields an irreducible, but nonreduced root system):

```
sage: CartanType(["BC", 4, 2]).dynkin_diagram()
O=<=O---O---O=<=O
0   1   2   3   4
BC4~
```

This includes the two degenerate cases:

```
sage: CartanType(["A", 1, 1]).dynkin_diagram()
O<=>O
0   1
A1~
sage: CartanType(["BC", 1, 2]).dynkin_diagram()
  4
O=<=O
0   1
```

```
BC1~
```

For the user convenience, Kac's notations for twisted affine types are automatically translated into the previous ones:

```
sage: CartanType(["A", 9, 2])
['B', 5, 1]^*
sage: CartanType(["A", 9, 2]).dynkin_diagram()
    O 0
    |
    |
O---O---O---O=<=O
1   2   3   4   5
B5~*
sage: CartanType(["A", 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
0   1   2   3   4   5
BC5~
sage: CartanType(["D", 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
C4~*
sage: CartanType(["D", 4, 3]).dynkin_diagram()
  3
O=>=O---O
2   1   0
G2~* relabelled by {0: 0, 1: 2, 2: 1}
sage: CartanType(["E", 6, 2]).dynkin_diagram()
O---O---O=<=O---O
0   1   2   3   4
F4~*
```

Additionally one can set the notation global option to use Kac's notation:

```
sage: CartanType.global_options['notation'] = 'Kac'
sage: CartanType(["A", 9, 2])
['A', 9, 2]
sage: CartanType(["A", 9, 2]).dynkin_diagram()
    O 0
    |
    |
O---O---O---O=<=O
1   2   3   4   5
A9^2
sage: CartanType(["A", 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
0   1   2   3   4   5
A10^2
sage: CartanType(["D", 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
D5^2
sage: CartanType(["D", 4, 3]).dynkin_diagram()
  3
O=>=O---O
2   1   0
D4^3
sage: CartanType(["E", 6, 2]).dynkin_diagram()
O---O---O=<=O---O
```

```
0   1   2   3   4
E6^2
sage: CartanType.global_options['notation'] = 'BC'
```

Todo

Should those indexes come before the introduction?

class sage.combinat.root_system.cartan_type.**CartanTypeFactory**
Bases: sage.structure.sage_object.SageObject

classmethod color(*i*)
Default color scheme for the vertices of a Dynkin diagram (and associated objects)

EXAMPLES:

```
sage: CartanType.color(1)
'blue'
sage: CartanType.color(2)
'red'
sage: CartanType.color(3)
'green'
```

The default color is black:

```
sage: CartanType.color(0)
'black'
```

Negative indices get the same color as their positive counterparts:

```
sage: CartanType.color(-1)
'blue'
sage: CartanType.color(-2)
'red'
sage: CartanType.color(-3)
'green'
```

global_options(**get_value*, ***set_value*)
Sets and displays the global options for Cartan types. If no parameters are set, then the function returns a copy of the options dictionary.

The `options` to partitions can be accessed as the method `CartanType.global_options` of `CartanType`.

OPTIONS:

- `dual_latex` – (default: `\vee`) The latex used for dual CartanTypes when latexing
- `dual_str` – (default: `*`) The string used for dual Cartan types when printing
- `latex_marked` – (default: `True`) Indicate in the latex output if a Cartan type has been marked
- `latex_relabel` – (default: `True`) Indicate in the latex output if a Cartan type has been relabelled
- `mark_special_node` – (default: `none`) Make the special nodes
  - `both` – both in latex and printing
  - `latex` – only in latex
  - `none` – no markup
  - `printing` – only in printing
- `marked_node_str` – (default: `X`) The string used to indicate a marked node when printing
- `notation` – (default: `Stembridge`) Specifies which notation Cartan types should use when printed

– `BC` – alias for `Stembridge`

– `Kac` – use Kac's notation

– `Stembridge` – use Stembridge's notation

– `tilde` – alias for `Stembridge`

– `twisted` – alias for `Kac`

• `special_node_str` – (default: `@`) The string used to indicate which node is special when printing

EXAMPLES:

```
sage: ct = CartanType(['D',5,2]); ct
['C', 4, 1]^*
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
C4~*
sage: latex(ct)
C_{4}^{(1)\vee}
sage: CartanType.global_options(dual_str='#', dual_latex='\\ast',)
sage: ct
['C', 4, 1]^#
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
C4~#
sage: latex(ct)
C_{4}^{(1)\ast}
sage: CartanType.global_options(notation='kac', mark_special_node='both')
sage: ct
['D', 5, 2]
sage: ct.dynkin_diagram()
@=<=O---O---O=>=O
0   1   2   3   4
D5^2
sage: latex(ct)
D_{5}^{(2)}
```

For type $A_{2n}^{(2)\dagger}$, the dual string/latex options are automatically overriden:

```
sage: dct = CartanType(['A',8,2]).dual(); dct
['A', 8, 2]^+
sage: latex(dct)
A_{8}^{(2)\dagger}
sage: dct.dynkin_diagram()
@=>=O---O---O=>=O
0   1   2   3   4
A8^2+
sage: CartanType.global_options.reset()
```

See `GlobalOptions` for more features of these options.

samples (*finite=None*, *affine=None*, *crystallographic=None*)

Return a sample of the available Cartan types.

INPUT:

• `finite` – a boolean or `None` (default: `None`)

• `affine` – a boolean or `None` (default: `None`)

- `crystallographic` – a boolean or `None` (default: `None`)

The sample contains all the exceptional finite and affine Cartan types, as well as typical representatives of the infinite families.

EXAMPLES:

```
sage: CartanType.samples()
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
 ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2], ['I', 5], ['H', 3], ['H', 4],
 ['A', 1, 1], ['A', 5, 1], ['B', 1, 1], ['B', 5, 1],
 ['C', 1, 1], ['C', 5, 1], ['D', 3, 1], ['D', 5, 1],
 ['E', 6, 1], ['E', 7, 1], ['E', 8, 1], ['F', 4, 1], ['G', 2, 1], ['BC', 1, 2], ['BC', 5, 2]
 ['B', 5, 1]^*, ['C', 4, 1]^*, ['F', 4, 1]^*, ['G', 2, 1]^*, ['BC', 1, 2]^*, ['BC', 5, 2]^*]
```

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

```
sage: CartanType.samples(finite=True)
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
 ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2], ['I', 5], ['H', 3], ['H', 4]]

sage: CartanType.samples(affine=True)
[['A', 1, 1], ['A', 5, 1], ['B', 1, 1], ['B', 5, 1],
 ['C', 1, 1], ['C', 5, 1], ['D', 3, 1], ['D', 5, 1],
 ['E', 6, 1], ['E', 7, 1], ['E', 8, 1], ['F', 4, 1], ['G', 2, 1], ['BC', 1, 2], ['BC', 5, 2]
 ['B', 5, 1]^*, ['C', 4, 1]^*, ['F', 4, 1]^*, ['G', 2, 1]^*, ['BC', 1, 2]^*, ['BC', 5, 2]^*]

sage: CartanType.samples(crystallographic=True)
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
 ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2],
 ['A', 1, 1], ['A', 5, 1], ['B', 1, 1], ['B', 5, 1],
 ['C', 1, 1], ['C', 5, 1], ['D', 3, 1], ['D', 5, 1],
 ['E', 6, 1], ['E', 7, 1], ['E', 8, 1], ['F', 4, 1], ['G', 2, 1], ['BC', 1, 2], ['BC', 5, 2]
 ['B', 5, 1]^*, ['C', 4, 1]^*, ['F', 4, 1]^*, ['G', 2, 1]^*, ['BC', 1, 2]^*, ['BC', 5, 2]^*]

sage: CartanType.samples(crystallographic=False)
[['I', 5], ['H', 3], ['H', 4]]
```

Todo

add some reducible Cartan types (suggestions?)

TESTS:

```
sage: for ct in CartanType.samples(): TestSuite(ct).run()
```

class sage.combinat.root_system.cartan_type.**CartanType_abstract**

Bases: `object`

Abstract class for Cartan types

Subclasses should implement:

- `dynkin_diagram()`
- `cartan_matrix()`
- `is_finite()`
- `is_affine()`

- is_irreducible()

as_folding(*folding_of=None*, *sigma=None*)

Return self realized as a folded Cartan type.

For finite and affine types, this is realized by the Dynkin diagram foldings:

$$\begin{aligned} C_n^{(1)}, A_{2n}^{(2)}, A_{2n}^{(2)\dagger}, D_{n+1}^{(2)} &\hookrightarrow A_{2n-1}^{(1)}, \\ A_{2n-1}^{(2)}, B_n^{(1)} &\hookrightarrow D_{n+1}^{(1)}, \\ E_6^{(2)}, F_4^{(1)} &\hookrightarrow E_6^{(1)}, \\ D_4^{(3)}, G_2^{(1)} &\hookrightarrow D_4^{(1)}, \\ C_n &\hookrightarrow A_{2n-1}, \\ B_n &\hookrightarrow D_{n+1}, \\ F_4 &\hookrightarrow E_6, \\ G_2 &\hookrightarrow D_4. \end{aligned}$$

For general types, this returns self as a folded type of self with σ as the identity map.

For more information on these foldings and folded Cartan types, see sage.combinat.root_system.type_folded.CartanTypeFolded.

If the optional inputs folding_of and sigma are specified, then this returns the folded Cartan type of self in folding_of given by the automorphism sigma.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).as_folding()
['B', 3, 1] as a folding of  ['D', 4, 1]
sage: CartanType(['F', 4]).as_folding()
['F', 4] as a folding of  ['E', 6]
sage: CartanType(['BC', 3, 2]).as_folding()
['BC', 3, 2] as a folding of  ['A', 5, 1]
sage: CartanType(['D', 4, 3]).as_folding()
['G', 2, 1]^* relabelled by {0: 0, 1: 2, 2: 1} as a folding of ['D', 4, 1]
```

coxeter_diagram()

Return the Coxeter diagram for self.

EXAMPLES:

```
sage: CartanType(['B',3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A',3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 3)]
sage: CartanType(['B',3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4)]
sage: CartanType(['G',2]).coxeter_diagram().edges()
[(1, 2, 6)]
sage: CartanType(['F',4]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
```

coxeter_matrix()

Return the Coxeter matrix for self.

EXAMPLES:

```
sage: CartanType(['A', 4]).coxeter_matrix()
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

coxeter_type()
Return the Coxeter type for `self`.

EXAMPLES:

```
sage: CartanType(['A', 4]).coxeter_type()
Coxeter type of ['A', 4]
```

dual()
Return the dual Cartan type, possibly just as a formal dual.

EXAMPLES:

```
sage: CartanType(['A',3]).dual()
['A', 3]
sage: CartanType(["B", 3]).dual()
['C', 3]
sage: CartanType(['C',2]).dual()
['B', 2]
sage: CartanType(['D',4]).dual()
['D', 4]
sage: CartanType(['E',8]).dual()
['E', 8]
sage: CartanType(['F',4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

global_options(**get_value*, ***set_value*)
Sets and displays the global options for Cartan types. If no parameters are set, then the function returns a copy of the options dictionary.

The `options` to partitions can be accessed as the method `CartanType.global_options` of `CartanType`.

OPTIONS:

- `dual_latex` – (default: `\vee`) The latex used for dual CartanTypes when latexing
- `dual_str` – (default: `*`) The string used for dual Cartan types when printing
- `latex_marked` – (default: `True`) Indicate in the latex output if a Cartan type has been marked
- `latex_relabel` – (default: `True`) Indicate in the latex output if a Cartan type has been relabelled
- `mark_special_node` – (default: `none`) Make the special nodes
  - `both` – both in latex and printing
  - `latex` – only in latex
  - `none` – no markup
  - `printing` – only in printing
- `marked_node_str` – (default: `X`) The string used to indicate a marked node when printing
- `notation` – (default: `Stembridge`) Specifies which notation Cartan types should use when printed
  - `BC` – alias for `Stembridge`
  - `Kac` – use Kac's notation
  - `Stembridge` – use Stembridge's notation
  - `tilde` – alias for `Stembridge`

– `twisted` – alias for `Kac`

• `special_node_str` – (default: `@`) The string used to indicate which node is special when printing

EXAMPLES:

```
sage: ct = CartanType(['D',5,2]); ct
['C', 4, 1]^*
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
C4~*
sage: latex(ct)
C_{4}^{(1)\vee}
sage: CartanType.global_options(dual_str='#', dual_latex='\\ast',)
sage: ct
['C', 4, 1]^#
sage: ct.dynkin_diagram()
O=<=O---O---O=>=O
0   1   2   3   4
C4~#
sage: latex(ct)
C_{4}^{(1)\ast}
sage: CartanType.global_options(notation='kac', mark_special_node='both')
sage: ct
['D', 5, 2]
sage: ct.dynkin_diagram()
@=<=O---O---O=>=O
0   1   2   3   4
D5^2
sage: latex(ct)
D_{5}^{(2)}
```

For type $A_{2n}^{(2)\dagger}$, the dual string/latex options are automatically overriden:

```
sage: dct = CartanType(['A',8,2]).dual(); dct
['A', 8, 2]^+
sage: latex(dct)
A_{8}^{(2)\dagger}
sage: dct.dynkin_diagram()
@=>=O---O---O=>=O
0   1   2   3   4
A8^2+
sage: CartanType.global_options.reset()
```

See `GlobalOptions` for more features of these options.

index_set()

Return the index set for `self`.

This is the list of the nodes of the associated Coxeter or Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
```

```
sage: CartanType(['A', 6, 2]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 6, 2]).index_set()
(0, 1, 2, 3, 4, 5)
sage: CartanType(['E', 6, 1]).index_set()
(0, 1, 2, 3, 4, 5, 6)
sage: CartanType(['E', 6, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CartanType(['A', 2, 2]).index_set()
(0, 1)
sage: CartanType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CartanType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)
```

is_affine()

Return whether `self` is affine.

EXAMPLES:

```
sage: CartanType(['A', 3]).is_affine()
False
sage: CartanType(['A', 3, 1]).is_affine()
True
```

is_atomic()

This method is usually equivalent to `is_reducible()`, except for the Cartan type D_2.

D_2 is not a standard Cartan type. It is equivalent to type $A_1 \times A_1$ which is reducible; however the isomorphism from its ambient space (for the orthogonal group of degree 4) to that of $A_1 \times A_1$ is non trivial, and it is useful to have it.

From a programming point of view its implementation is more similar to the irreducible types, and so the method `is_atomic()` is supplied.

EXAMPLES:

```
sage: CartanType("D2").is_atomic()
True
sage: CartanType("D2").is_irreducible()
False
```

TESTS:

```
sage: all( T.is_irreducible() == T.is_atomic() for T in CartanType.samples() if T != CartanT
True
```

is_compound()

A short hand for not `is_atomic()`.

TESTS:

```
sage: all( T.is_compound() == (not T.is_atomic()) for T in CartanType.samples())
True
```

is_crystallographic()

Return whether this Cartan type is crystallographic.

This returns `False` by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: [ [t, t.is_crystallographic() ] for t in CartanType.samples(finite=True) ]
[[['A', 1], True], [['A', 5], True],
 [['B', 1], True], [['B', 5], True],
 [['C', 1], True], [['C', 5], True],
 [['D', 2], True], [['D', 3], True], [['D', 5], True],
 [['E', 6], True], [['E', 7], True], [['E', 8], True],
 [['F', 4], True], [['G', 2], True],
 [['I', 5], False], [['H', 3], False], [['H', 4], False]]
```

is_finite()

Return whether this Cartan type is finite.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_finite()
Traceback (most recent call last):
...
NotImplementedError: <abstract method is_finite at ...>

sage: CartanType(['A',4]).is_finite()
True
sage: CartanType(['A',4, 1]).is_finite()
False
```

is_implemented()

Check whether the Cartan datum for `self` is actually implemented.

EXAMPLES:

```
sage: CartanType(["A",4,1]).is_implemented()
True
sage: CartanType(['H',3]).is_implemented()
True
```

is_irreducible()

Report whether this Cartan type is irreducible (i.e. simple). This should be overridden in any subclass.

This returns `False` by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_irreducible()
False
```

is_reducible()

Report whether the root system is reducible (i.e. not simple), that is whether it can be factored as a product of root systems.

EXAMPLES:

```
sage: CartanType("A2xB3").is_reducible()
True
sage: CartanType(['A',2]).is_reducible()
False
```

is_simply_laced()

Return whether this Cartan type is simply laced.

This returns `False` by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: [ [t, t.is_simply_laced() ] for t in CartanType.samples() ]
[[['A', 1], True], [['A', 5], True],
 [['B', 1], True], [['B', 5], False],
 [['C', 1], True], [['C', 5], False],
 [['D', 2], True], [['D', 3], True], [['D', 5], True],
 [['E', 6], True], [['E', 7], True], [['E', 8], True],
 [['F', 4], False], [['G', 2], False], [['I', 5], False], [['H', 3], False], [['H', 4], Fals
 [['A', 1, 1], False], [['A', 5, 1], True],
 [['B', 1, 1], False], [['B', 5, 1], False],
 [['C', 1, 1], False], [['C', 5, 1], False],
 [['D', 3, 1], True], [['D', 5, 1], True],
 [['E', 6, 1], True], [['E', 7, 1], True], [['E', 8, 1], True],
 [['F', 4, 1], False], [['G', 2, 1], False],
 [['BC', 1, 2], False], [['BC', 5, 2], False],
 [['B', 5, 1]^*, False], [['C', 4, 1]^*, False], [['F', 4, 1]^*, False], [['G', 2, 1]^*, Fal
 [['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False]]
```

marked_nodes (*marked_nodes*)

Return a Cartan type with the nodes `marked_nodes` marked.

INPUT:

- `marked_nodes` – a list of nodes to mark

EXAMPLES:

```
sage: CartanType(['F',4]).marked_nodes([1, 3]).dynkin_diagram()
X---O=>=X---O
1   2   3   4
F4 with nodes (1, 3) marked
```

rank()

Return the rank of `self`.

This is the number of nodes of the associated Coxeter or Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['A', 4]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['I', 8]).rank()
2
```

relabel (*relabelling*)

Return a relabelled copy of this Cartan type.

INPUT:

- `relabelling` – a function (or a list or dictionary)

OUTPUT:

an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label `i` is relabelled `f(i)` (or, by `f[i]` if `f` is a list or dictionary).

EXAMPLES:

```
sage: CartanType(['F',4]).relabel({ 1:4, 2:3, 3:2, 4:1 }).dynkin_diagram()
O---O=>=O---O
4   3   2   1
F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

root_system()
Return the root system associated to `self`.

EXAMPLES:

```
sage: CartanType(['A',4]).root_system()
Root system of type ['A', 4]
```

subtype(*index_set*)
Return a subtype of `self` given by `index_set`.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of `self` by `index_set`.

EXAMPLES:

```
sage: ct = CartanType(['A',6,2])
sage: ct.dynkin_diagram()
O=<=O---O=<=O
0   1   2   3
BC3~
sage: ct.subtype([1,2,3])
['C', 3]
```

type()
Return the type of `self`, or `None` if unknown.

This method should be overridden in any subclass.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.type() is None
True
```

class sage.combinat.root_system.cartan_type.**CartanType_affine**
Bases: sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

An abstract class for simple affine Cartan types

AmbientSpace
alias of AmbientSpace

a()
Return the unique minimal non trivial annihilating linear combination of $\alpha_0^\vee, \alpha^\vee, \ldots, \alpha^\vee$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

a is a shortcut for col_annihilator:

```
sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

acheck(*m=None*)

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument m is for internal use only.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

acheck is a shortcut for row_annihilator:

```
sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

FIXME:

- The current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.
- This really should be a method of CartanMatrix.

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```
sage: CartanType(['A', 1, 1]).basic_untwisted()
['A', 1]
sage: CartanType(['A', 3, 1]).basic_untwisted()
['A', 3]
sage: CartanType(['B', 3, 1]).basic_untwisted()
['B', 3]
sage: CartanType(['E', 6, 1]).basic_untwisted()
['E', 6]
```

```
sage: CartanType(['G', 2, 1]).basic_untwisted()
['G', 2]

sage: CartanType(['A', 2, 2]).basic_untwisted()
['A', 2]
sage: CartanType(['A', 4, 2]).basic_untwisted()
['A', 4]
sage: CartanType(['A', 11, 2]).basic_untwisted()
['A', 11]
sage: CartanType(['D', 5, 2]).basic_untwisted()
['D', 5]
sage: CartanType(['E', 6, 2]).basic_untwisted()
['E', 6]
sage: CartanType(['D', 4, 3]).basic_untwisted()
['D', 4]
```

c()

Returns the family (c_i)_i of integer coefficients defined by $c_i = max(1, a_i/a^vee_i)$ (see e.g. [FSS07] p. 3)

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().c()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().c()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().c()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().c()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
```

TESTS:

```
sage: CartanType(["B", 3, 1]).c().map(parent)
Finite family {0: Integer Ring, 1: Integer Ring, 2: Integer Ring, 3: Integer Ring}
```

REFERENCES:

classical()

Return the classical Cartan type associated with this affine Cartan type.

EXAMPLES:

```
sage: CartanType(['A', 1, 1]).classical()
['A', 1]
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]

sage: CartanType(['A', 2, 2]).classical()
['C', 1]
sage: CartanType(['BC', 1, 2]).classical()
['C', 1]
sage: CartanType(['A', 4, 2]).classical()
['C', 2]
sage: CartanType(['BC', 2, 2]).classical()
```

```
['C', 2]
sage: CartanType(['A', 10, 2]).classical()
['C', 5]
sage: CartanType(['BC', 5, 2]).classical()
['C', 5]

sage: CartanType(['D', 5, 2]).classical()
['B', 4]
sage: CartanType(['E', 6, 1]).classical()
['E', 6]
sage: CartanType(['G', 2, 1]).classical()
['G', 2]
sage: CartanType(['E', 6, 2]).classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: CartanType(['D', 4, 3]).classical()
['G', 2]
```

We check that `classical()`, `sage.combinat.root_system.cartan_type.CartanType_crystallograp` and `special_node()` are consistent:

```
sage: for ct in CartanType.samples(affine = True):
...       g1 = ct.classical().dynkin_diagram()
...       g2 = ct.dynkin_diagram()
...       g2.delete_vertex(ct.special_node())
...       assert sorted(g1.vertices()) == sorted(g2.vertices())
...       assert sorted(g1.edges()) == sorted(g2.edges())
```

col_annihilator()

Return the unique minimal non trivial annihilating linear combination of $\alpha_0^\vee, \alpha^\vee, \ldots, \alpha^\vee$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

`a` is a shortcut for col_annihilator:

```
sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

is_affine()

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_affine()
True
```

is_finite()

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_finite()
False
```

is_untwisted_affine()

Return whether `self` is untwisted affine

A Cartan type is untwisted affine if it is the canonical affine extension of some finite type. Every affine type is either untwisted affine, dual thereof, or of type `BC`.

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_untwisted_affine()
True
sage: CartanType(['A', 3, 1]).dual().is_untwisted_affine() # this one is self dual!
True
sage: CartanType(['B', 3, 1]).dual().is_untwisted_affine()
False
sage: CartanType(['BC', 3, 2]).is_untwisted_affine()
False
```

other_affinization()

Return the other affinization of the same classical type.

EXAMPLES:

```
sage: CartanType(["A", 3, 1]).other_affinization()
['A', 3, 1]
sage: CartanType(["B", 3, 1]).other_affinization()
['C', 3, 1]^*
sage: CartanType(["C", 3, 1]).dual().other_affinization()
['B', 3, 1]
```

Is this what we want?:

```
sage: CartanType(["BC", 3, 2]).dual().other_affinization()
['B', 3, 1]
```

row_annihilator(*m=None*)

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument `m` is for internal use only.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

`acheck` is a shortcut for row_annihilator:

```
sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

FIXME:

- The current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.
- This really should be a method of `CartanMatrix`.

special_node()

Return a special node of the Dynkin diagram.

A *special* node is a node of the Dynkin diagram such that pruning it yields a Dynkin diagram for the associated classical type (see `classical()`).

This method returns the label of some special node. This is usually 0 in the standard conventions.

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).special_node()
0
```

The choice is guaranteed to be consistent with the indexing of the nodes of the classical Dynkin diagram:

```
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['A', 3, 1]).classical().index_set()
(1, 2, 3)
```

special_nodes()

Return the set of special nodes of the affine Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['A',3,1]).special_nodes()
(0, 1, 2, 3)
sage: CartanType(['C',2,1]).special_nodes()
(0, 2)
sage: CartanType(['D',4,1]).special_nodes()
(0, 1, 3, 4)
sage: CartanType(['E',6,1]).special_nodes()
(0, 1, 6)
sage: CartanType(['D',3,2]).special_nodes()
(0, 2)
sage: CartanType(['A',4,2]).special_nodes()
(0,)
```

translation_factors()

Returns the translation factors for `self`. Those are the smallest factors t_i such that the translation by $t_i \alpha_i$ maps the fundamental polygon to another polygon in the alcove picture.

OUTPUT: a dictionary from `self.index_set()` to $\mathbf{Z}$ (or $\mathbf{Q}$ for affine type BC)

Those coefficients are all 1 for dual untwisted, and in particular for simply laced. They coincide with the usual c_i coefficients (see `c()`) for untwisted and dual thereof. See the discussion below for affine type BC.

Note: one usually realizes the alcove picture in the coweight lattice, with translations by coroots; in that case, one will use the translation factors for the dual Cartan type.

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.

EXAMPLES:

```
sage: CartanType(['C',2,1]).translation_factors()
Finite family {0: 1, 1: 2, 2: 1}
sage: CartanType(['C',2,1]).dual().translation_factors()
Finite family {0: 1, 1: 1, 2: 1}
sage: CartanType(['D',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['F',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
sage: CartanType(['BC',4,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1/2}
```

We proceed with systematic tests taken from MuPAD-Combinat's testsuite:

```
sage: list(CartanType(["A", 1, 1]).translation_factors())
[1, 1]
sage: list(CartanType(["A", 5, 1]).translation_factors())
[1, 1, 1, 1, 1, 1]
sage: list(CartanType(["B", 5, 1]).translation_factors())
[1, 1, 1, 1, 1, 2]
sage: list(CartanType(["C", 5, 1]).translation_factors())
[1, 2, 2, 2, 2, 1]
sage: list(CartanType(["D", 5, 1]).translation_factors())
[1, 1, 1, 1, 1, 1]
sage: list(CartanType(["E", 6, 1]).translation_factors())
[1, 1, 1, 1, 1, 1, 1]
sage: list(CartanType(["E", 7, 1]).translation_factors())
[1, 1, 1, 1, 1, 1, 1, 1]
sage: list(CartanType(["E", 8, 1]).translation_factors())
[1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: list(CartanType(["F", 4, 1]).translation_factors())
[1, 1, 1, 2, 2]
sage: list(CartanType(["G", 2, 1]).translation_factors())
[1, 3, 1]
sage: list(CartanType(["A", 2, 2]).translation_factors())
[1, 1/2]
sage: list(CartanType(["A", 2, 2]).dual().translation_factors())
[1/2, 1]
sage: list(CartanType(["A", 10, 2]).translation_factors())
[1, 1, 1, 1, 1, 1/2]
sage: list(CartanType(["A", 10, 2]).dual().translation_factors())
[1/2, 1, 1, 1, 1, 1]
sage: list(CartanType(["A", 9, 2]).translation_factors())
[1, 1, 1, 1, 1, 1]
sage: list(CartanType(["D", 5, 2]).translation_factors())
[1, 1, 1, 1, 1]
sage: list(CartanType(["D", 4, 3]).translation_factors())
[1, 1, 1]
sage: list(CartanType(["E", 6, 2]).translation_factors())
[1, 1, 1, 1, 1]
```

We conclude with a discussion of the appropriate value for affine type BC. Let us consider the alcove picture realized in the weight lattice. It is obtained by taking the level-1 affine hyperplane in the weight lattice, and projecting it along Λ_0:

```
sage: R = RootSystem(["BC",2,2])
sage: alpha = R.weight_space().simple_roots()
sage: alphacheck = R.coroot_space().simple_roots()
sage: Lambda = R.weight_space().fundamental_weights()
```

Here are the levels of the fundamental weights:

```
sage: Lambda[0].level(), Lambda[1].level(), Lambda[2].level()
(1, 2, 2)
```

So the "center" of the fundamental polygon at level 1 is:

```
sage: O = Lambda[0]
sage: O.level()
1
```

We take the projection ω_1 at level 0 of Λ_1 as unit vector on the x-axis, and the projection ω_2 at level 0 of Λ_2 as unit vector of the y-axis:

```
sage: omega1 = Lambda[1]-2*Lambda[0]
sage: omega2 = Lambda[2]-2*Lambda[0]
sage: omega1.level(), omega2.level()
(0, 0)
```

The projections of the simple roots can be read off:

```
sage: alpha[0]
2*Lambda[0] - Lambda[1]
sage: alpha[1]
-2*Lambda[0] + 2*Lambda[1] - Lambda[2]
sage: alpha[2]
-2*Lambda[1] + 2*Lambda[2]
```

Namely $\alpha_0 = -\omega_1$, $\alpha_1 = 2\omega_1 - \omega_2$ and $\alpha_2 = -2\omega_1 + 2\omega_2$.

The reflection hyperplane defined by $\alpha_0^\vee$ goes through the points $O + 1/2\omega_1$ and $O + 1/2\omega_2$:

```
sage: (O+(1/2)*omega1).scalar(alphacheck[0])
0
sage: (O+(1/2)*omega2).scalar(alphacheck[0])
0
```

Hence, the fundamental alcove is the triangle $(O, O + 1/2\omega_1, O + 1/2\omega_2)$. By successive reflections, one can tile the full plane. This induces a tiling of the full plane by translates of the fundamental polygon.

Todo

Add the picture here, once root system plots in the weight lattice will be implemented. In the mean time, the reader may look up the dual picture on Figure 2 of [HST09] which was produced by MuPAD-Combinat.

From this picture, one can read that translations by α_0, α_1, and $1/2\alpha_2$ map the fundamental polygon to translates of it in the alcove picture, and are smallest with this property. Hence, the translation factors for affine type BC are $t_0 = 1, t_1 = 1, t_2 = 1/2$:

```
sage: CartanType(['BC',2,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1/2}
```

TESTS:

```
sage: CartanType(["B", 3, 1]).translation_factors().map(parent)
Finite family {0: Integer Ring, 1: Integer Ring, 2: Integer Ring, 3: Integer Ring}
sage: CartanType(["BC", 3, 2]).translation_factors().map(parent)
Finite family {0: Integer Ring, 1: Integer Ring, 2: Integer Ring, 3: Rational Field}
```

REFERENCES:

class sage.combinat.root_system.cartan_type.**CartanType_crystallographic**
Bases: sage.combinat.root_system.cartan_type.CartanType_abstract

An abstract class for crystallographic Cartan types.

ascii_art(*label='lambda x: x'*, *node=None*)
Return an ascii art representation of the Dynkin diagram.

INPUT:

- label – (default: the identity) a relabeling function for the nodes
- node – (optional) a function which returns the character for a node

EXAMPLES:

```
sage: cartan_type = CartanType(['B',5,1])
sage: print cartan_type.ascii_art()
    O 0
    |
    |
O---O---O---O=>=O
1   2   3   4   5
```

The label option is useful to visualize various statistics on the nodes of the Dynkin diagram:

```
sage: a = cartan_type.col_annihilator(); a
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 2, 5: 2}
sage: print CartanType(['B',5,1]).ascii_art(label=a.__getitem__)
    O 1
    |
    |
O---O---O---O=>=O
1   2   2   2   2
```

cartan_matrix()
Return the Cartan matrix associated with self.

EXAMPLES:

```
sage: CartanType(['A',4]).cartan_matrix()
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
```

coxeter_diagram()
Return the Coxeter diagram for self.

This implementation constructs it from the Dynkin diagram.

See also:

CartanType_abstract.coxeter_diagram()

EXAMPLES:

```
sage: CartanType(['A',3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A',3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 3)]
sage: CartanType(['B',3]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4)]
```

```
sage: CartanType(['G',2]).coxeter_diagram().edges()
[(1, 2, 6)]
sage: CartanType(['F',4]).coxeter_diagram().edges()
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
sage: CartanType(['A',2,2]).coxeter_diagram().edges()
[(0, 1, +Infinity)]
```

dynkin_diagram()

Return the Dynkin diagram associated with `self`.

EXAMPLES:

```
sage: CartanType(['A',4]).dynkin_diagram()
O---O---O---O
1   2   3   4
A4
```

Note: Derived subclasses should typically implement this as a cached method.

---

index_set_bipartition()

Return a bipartition $\{L, R\}$ of the vertices of the Dynkin diagram.

For i and j both in L (or both in R), the simple reflections s_i and s_j commute.

Of course, the Dynkin diagram should be bipartite. This is always the case for all finite types.

EXAMPLES:

```
sage: CartanType(['A',5]).index_set_bipartition()
({1, 3, 5}, {2, 4})

sage: CartanType(['A',2,1]).index_set_bipartition()
Traceback (most recent call last):
...
ValueError: the Dynkin diagram must be bipartite
```

is_crystallographic()

Implements `CartanType_abstract.is_crystallographic()` by returning `True`.

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_crystallographic()
True
```

symmetrizer()

Return the symmetrizer of the Cartan matrix of `self`.

A Cartan matrix M is symmetrizable if there exists a non trivial diagonal matrix D such that DM is a symmetric matrix, that is $DM = M^t D$. In that case, D is unique, up to a scalar factor for each connected component of the Dynkin diagram.

This method computes the unique minimal such D with positive integral coefficients. If D exists, it is returned as a family. Otherwise `None` is returned.

The coefficients are coerced to `base_ring`.

EXAMPLES:

```
sage: CartanType(["B",5]).symmetrizer()
Finite family {1: 2, 2: 2, 3: 2, 4: 2, 5: 1}
```

Here is a neat trick to visualize it better:

```
sage: T = CartanType(["B",5])
sage: print T.ascii_art(T.symmetrizer().__getitem__)
O---O---O---O=>=O
2   2   2   2   1

sage: T = CartanType(["BC",5, 2])
sage: print T.ascii_art(T.symmetrizer().__getitem__)
O=<=O---O---O---O=<=O
1   2   2   2   2   4
```

Here is the symmetrizer of some reducible Cartan types:

```
sage: T = CartanType(["D", 2])
sage: print T.ascii_art(T.symmetrizer().__getitem__)
O   O
1   1

sage: T = CartanType(["B",5],["BC",5, 2])
sage: print T.ascii_art(T.symmetrizer().__getitem__)
O---O---O---O=>=O
2   2   2   2   1
O=<=O---O---O---O=<=O
1   2   2   2   2   4
```

Property: up to an overall scalar factor, this gives the norm of the simple roots in the ambient space::

```
sage: T = CartanType(["C",5])
sage: print T.ascii_art(T.symmetrizer().__getitem__)
O---O---O---O=<=O
1   1   1   1   2

sage: alpha = RootSystem(T).ambient_space().simple_roots()
sage: print T.ascii_art(lambda i: alpha[i].scalar(alpha[i]))
O---O---O---O=<=O
2   2   2   2   4
```

class sage.combinat.root_system.cartan_type.**CartanType_decorator**(*ct*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject, sage.combinat.root_system.cartan_type.CartanType_

Concrete base class for Cartan types that decorate another Cartan type.

index_set()

EXAMPLES:

```
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.index_set()
(0, 1, 2, 3, 4)
```

is_affine()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_affine()
False
```

is_crystallographic()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_crystallographic()
True
```

is_finite()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_finite()
True
```

is_irreducible()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_irreducible()
True
```

rank()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.rank()
2
```

class sage.combinat.root_system.cartan_type.**CartanType_finite**

Bases: sage.combinat.root_system.cartan_type.CartanType_abstract

An abstract class for simple affine Cartan types.

is_affine()

EXAMPLES:

```
sage: CartanType(["A", 3]).is_affine()
False
```

is_finite()

EXAMPLES:

```
sage: CartanType(["A", 3]).is_finite()
True
```

class sage.combinat.root_system.cartan_type.**CartanType_simple**

Bases: sage.combinat.root_system.cartan_type.CartanType_abstract

An abstract class for simple Cartan types.

is_irreducible()

Return whether `self` is irreducible, which is `True`.

EXAMPLES:

```
sage: CartanType(['A', 3]).is_irreducible()
True
```

class sage.combinat.root_system.cartan_type.**CartanType_simple_finite**
Bases: object

class sage.combinat.root_system.cartan_type.**CartanType_simply_laced**
Bases: sage.combinat.root_system.cartan_type.CartanType_crystallographic

An abstract class for simply laced Cartan types.

dual()
Simply laced Cartan types are self-dual, so return self.

EXAMPLES:

```
sage: CartanType(["A", 3]).dual()
['A', 3]
sage: CartanType(["A", 3, 1]).dual()
['A', 3, 1]
sage: CartanType(["D", 3]).dual()
['D', 3]
sage: CartanType(["D", 4, 1]).dual()
['D', 4, 1]
sage: CartanType(["E", 6]).dual()
['E', 6]
sage: CartanType(["E", 6, 1]).dual()
['E', 6, 1]
```

is_simply_laced()
Return whether self is simply laced, which is True.

EXAMPLES:

```
sage: CartanType(['A',3,1]).is_simply_laced()
True
sage: CartanType(['A',2]).is_simply_laced()
True
```

class sage.combinat.root_system.cartan_type.**CartanType_standard_affine**(*letter*, *n*, *affine=1*)
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject, sage.combinat.root_system.cartan_type.CartanType_

A concrete class for affine simple Cartan types.

index_set()
Implements CartanType_abstract.index_set().

The index set for all standard affine Cartan types is of the form $\{0, \ldots, n\}$.

EXAMPLES:

```
sage: CartanType(['A', 5, 1]).index_set()
(0, 1, 2, 3, 4, 5)
```

rank()
Return the rank of self which for type $X_n^{(1)}$ is $n + 1$.

EXAMPLES:

```
sage: CartanType(['A', 4, 1]).rank()
5
sage: CartanType(['B', 4, 1]).rank()
5
```

```
sage: CartanType(['C', 3, 1]).rank()
4
sage: CartanType(['D', 4, 1]).rank()
5
sage: CartanType(['E', 6, 1]).rank()
7
sage: CartanType(['E', 7, 1]).rank()
8
sage: CartanType(['F', 4, 1]).rank()
5
sage: CartanType(['G', 2, 1]).rank()
3
sage: CartanType(['A', 2, 2]).rank()
2
sage: CartanType(['A', 6, 2]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['D', 5, 2]).rank()
5
sage: CartanType(['E', 6, 2]).rank()
5
sage: CartanType(['D', 4, 3]).rank()
3
```

special_node()

Implement `CartanType_abstract.special_node()`.

With the standard labelling conventions, 0 is always a special node.

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).special_node()
0
```

type()

Return the type of `self`.

EXAMPLES:

```
sage: CartanType(['A', 4, 1]).type()
'A'
```

class sage.combinat.root_system.cartan_type.**CartanType_standard_finite**(*letter*, *n*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject, sage.combinat.root_system.cartan_type.CartanType_

A concrete base class for the finite standard Cartan types.

This includes for example A_3, D_4, or E_8.

affine()

Return the corresponding untwisted affine Cartan type.

EXAMPLES:

```
sage: CartanType(['A',3]).affine()
['A', 3, 1]
```

coxeter_number()

Return the Coxeter number associated with `self`.

The Coxeter number is the order of a Coxeter element of the corresponding Weyl group.

See Bourbaki, Lie Groups and Lie Algebras V.6.1 or Wikipedia article Coxeter_element for more information.

EXAMPLES:

```
sage: CartanType(['A',4]).coxeter_number()
5
sage: CartanType(['B',4]).coxeter_number()
8
sage: CartanType(['C',4]).coxeter_number()
8
```

dual_coxeter_number()

Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['A',4]).dual_coxeter_number()
5
sage: CartanType(['B',4]).dual_coxeter_number()
7
sage: CartanType(['C',4]).dual_coxeter_number()
5
```

index_set()

Implements `CartanType_abstract.index_set()`.

The index set for all standard finite Cartan types is of the form $\{1, \ldots, n\}$. (See `type_I` for a slight abuse of this).

EXAMPLES:

```
sage: CartanType(['A', 5]).index_set()
(1, 2, 3, 4, 5)
```

opposition_automorphism()

Returns the opposition automorphism

The *opposition automorphism* is the automorphism $i \mapsto i^*$ of the vertices Dynkin diagram such that, for w_0 the longest element of the Weyl group, and any simple root α_i, one has $\alpha_{i^*} = -w_0(\alpha_i)$.

The automorphism is returned as a `Family`.

EXAMPLES:

```
sage: ct = CartanType(['A', 5])
sage: ct.opposition_automorphism()
Finite family {1: 5, 2: 4, 3: 3, 4: 2, 5: 1}

sage: ct = CartanType(['D', 4])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 4}

sage: ct = CartanType(['D', 5])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 5, 5: 4}

sage: ct = CartanType(['C', 4])
sage: ct.opposition_automorphism()
Finite family {1: 1, 2: 2, 3: 3, 4: 4}
```

rank()
Return the rank of `self` which for type X_n is n.

EXAMPLES:

```
sage: CartanType(['A', 3]).rank()
3
sage: CartanType(['B', 3]).rank()
3
sage: CartanType(['C', 3]).rank()
3
sage: CartanType(['D', 4]).rank()
4
sage: CartanType(['E', 6]).rank()
6
```

type()
Returns the type of `self`.

EXAMPLES:

```
sage: CartanType(['A', 4]).type()
'A'
sage: CartanType(['A', 4, 1]).type()
'A'
```

class sage.combinat.root_system.cartan_type.**CartanType_standard_untwisted_affine**(*letter*, *n*, *affine=1*)
Bases: sage.combinat.root_system.cartan_type.CartanType_standard_affine

A concrete class for the standard untwisted affine Cartan types.

basic_untwisted()
Return the basic_untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic_untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: CartanType(['A', 1, 1]).basic_untwisted()
['A', 1]
sage: CartanType(['A', 3, 1]).basic_untwisted()
['A', 3]
sage: CartanType(['B', 3, 1]).basic_untwisted()
['B', 3]
sage: CartanType(['E', 6, 1]).basic_untwisted()
['E', 6]
sage: CartanType(['G', 2, 1]).basic_untwisted()
['G', 2]
```

classical()
Return the classical Cartan type associated with `self`.

EXAMPLES:

```
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
sage: CartanType(['C', 3, 1]).classical()
```

```
['C', 3]
sage: CartanType(['D', 4, 1]).classical()
['D', 4]
sage: CartanType(['E', 6, 1]).classical()
['E', 6]
sage: CartanType(['F', 4, 1]).classical()
['F', 4]
sage: CartanType(['G', 2, 1]).classical()
['G', 2]
```

is_untwisted_affine()

Implement CartanType_affine.is_untwisted_affine() by returning True.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).is_untwisted_affine()
True
```

5.1.198 Coxeter Groups

sage.combinat.root_system.coxeter_group.**CoxeterGroup**(*data*, *implementation='reflection'*, *base_ring=None*, *index_set=None*)

Return an implementation of the Coxeter group given by data.

INPUT:

- data – a Cartan type (or coercible into; see CartanType) or a Coxeter matrix or graph
- implementation – (default: 'reflection') can be one of the following:
  - 'permutation' - as a permutation representation
  - 'matrix' - as a Weyl group (as a matrix group acting on the root space); if this is not implemented, this uses the "reflection" implementation
  - 'coxeter3' - using the coxeter3 package
  - 'reflection' - as elements in the reflection representation; see CoxeterMatrixGroup
- base_ring – (optional) the base ring for the 'reflection' implementation
- index_set – (optional) the index set for the 'reflection' implementation

EXAMPLES:

Now assume that data represents a Cartan type. If implementation is not specified, the reflection representation is returned:

```
sage: W = CoxeterGroup(["A",2])
sage: W
Finite Coxeter group over Universal Cyclotomic Field with Coxeter matrix:
[1 3]
[3 1]

sage: W = CoxeterGroup(["A",3,1]); W
Coxeter group over Universal Cyclotomic Field with Coxeter matrix:
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
```

```
[3 2 3 1]

sage: W = CoxeterGroup(['H',3]); W
Finite Coxeter group over Universal Cyclotomic Field with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]
```

We now use the `implementation` option:

```
sage: W = CoxeterGroup(["A",2], implementation = "permutation") # optional - chevie
sage: W                                                         # optional - chevie
Permutation Group with generators [(1,3)(2,5)(4,6), (1,4)(2,3)(5,6)]
sage: W.category()                          # optional - chevie
Join of Category of finite permutation groups and Category of finite coxeter groups

sage: W = CoxeterGroup(["A",2], implementation="matrix")
sage: W
Weyl Group of type ['A', 2] (as a matrix group acting on the ambient space)

sage: W = CoxeterGroup(["H",3], implementation="matrix")
sage: W
Finite Coxeter group over Universal Cyclotomic Field with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]

sage: W = CoxeterGroup(["H",3], implementation="reflection")
sage: W
Finite Coxeter group over Universal Cyclotomic Field with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]

sage: W = CoxeterGroup(["A",4,1], implementation="permutation")
Traceback (most recent call last):
...
NotImplementedError: Coxeter group of type ['A', 4, 1] as permutation group not implemented
```

We use the different options for the "reflection" implementation:

```
sage: W = CoxeterGroup(["H",3], implementation="reflection", base_ring=RR)
sage: W
Finite Coxeter group over Real Field with 53 bits of precision with Coxeter matrix:
[1 3 2]
[3 1 5]
[2 5 1]
sage: W = CoxeterGroup([[1,10],[10,1]], implementation="reflection", index_set=['a','b'], base_r
sage: W
Finite Coxeter group over Symbolic Ring with Coxeter matrix:
[ 1 10]
[10  1]
```

TESTS:

```
sage: W = groups.misc.CoxeterGroup(["H",3])
```

class sage.combinat.root_system.coxeter_group.**CoxeterGroupAsPermutationGroup**(*cartan_type*)

Bases: sage.structure.unique_representation.UniqueRepresentation,

sage.groups.perm_gps.permgroup.PermutationGroup_generic

Construct this Coxeter group as a Sage permutation group, by fetching the permutation representation of the generators from Chevie's database.

TESTS:

```
sage: from sage.combinat.root_system.coxeter_group import CoxeterGroupAsPermutationGroup
sage: W = CoxeterGroupAsPermutationGroup(CartanType(["H",3])) # optional - chevie
sage: TestSuite(W).run()              # optional - chevie
```

class Element

Bases: sage.groups.perm_gps.permgroup_element.PermutationGroupElement

has_descent(*i*, *side='right'*, *positive=False*)

Returns whether i is a (left/right) descent of self.

See sage.categories.coxeter_groups.CoxeterGroups.ElementMethods.descents() for a description of the options.

EXAMPLES:

```
sage: W = CoxeterGroup(["A",3])
sage: s = W.simple_reflections()
sage: w = s[1] * s[2] * s[3]
sage: w.has_descent(3)
True
sage: [ w.has_descent(i)                    for i in [1,2,3] ]
[False, False, True]
sage: [ w.has_descent(i, side = 'left')     for i in [1,2,3] ]
[True, False, False]
sage: [ w.has_descent(i, positive = True) for i in [1,2,3] ]
[True, True, False]
```

This implementation is a plain copy of that of CoxeterGroups. It is there as a workaround since *PermutationGroupElement* currently redefines abusively has_descent() as if the group was the full symmetric group.

has_left_descent(*i*)

Returns whether i is a descent of self by testing whether i is mapped to a negative root.

EXAMPLES:

```
sage: W = CoxeterGroup(["A",3], implementation = "permutation") # optional - chevie
sage: s = W.simple_reflections() # optional - chevie
sage: (s[1]*s[2]).has_left_descent(1) # optional - chevie
True
sage: (s[1]*s[2]).has_left_descent(2) # optional - chevie
False
```

CoxeterGroupAsPermutationGroup.**index_set**()

Returns the index set of this Coxeter group

EXAMPLES:

```
sage: W = CoxeterGroup(["H",3], implementation = "permutation")  # optional - chevie
sage: W.index_set() # optional - chevie
[1, 2, 3]
```

CoxeterGroupAsPermutationGroup.**reflection**(*i*)

Returns the i-th reflection of self.

For i in $1, \ldots, n$, this gives the i-th simple reflection of self.

EXAMPLES:

```
sage: W = CoxeterGroup(["H",3], implementation = "permutation") # optional - chevie
sage: W.simple_reflection(1) # optional - chevie
(1,16)(2,5)(4,7)(6,9)(8,10)(11,13)(12,14)(17,20)(19,22)(21,24)(23,25)(26,28)(27,29)
sage: W.simple_reflection(2) # optional - chevie
(1,4)(2,17)(3,6)(5,7)(9,11)(10,12)(14,15)(16,19)(18,21)(20,22)(24,26)(25,27)(29,30)
sage: W.simple_reflection(3) # optional - chevie
(2,6)(3,18)(4,8)(5,9)(7,10)(11,12)(13,14)(17,21)(19,23)(20,24)(22,25)(26,27)(28,29)
sage: W.reflection(4)        # optional - chevie
(1,5)(2,22)(3,11)(4,19)(7,17)(8,12)(9,13)(10,15)(16,20)(18,26)(23,27)(24,28)(25,30)
sage: W.reflection(5)        # optional - chevie
(1,22)(2,4)(3,9)(5,20)(6,13)(7,16)(8,14)(12,15)(17,19)(18,24)(21,28)(23,29)(27,30)
sage: W.reflection(6)        # optional - chevie
(1,8)(2,18)(3,17)(5,12)(6,21)(7,11)(9,10)(13,15)(16,23)(20,27)(22,26)(24,25)(28,30)
```

CoxeterGroupAsPermutationGroup.**simple_reflection**(i)

Returns the i-th reflection of `self`.

For i in $1, \ldots, n$, this gives the i-th simple reflection of `self`.

EXAMPLES:

```
sage: W = CoxeterGroup(["H",3], implementation = "permutation") # optional - chevie
sage: W.simple_reflection(1) # optional - chevie
(1,16)(2,5)(4,7)(6,9)(8,10)(11,13)(12,14)(17,20)(19,22)(21,24)(23,25)(26,28)(27,29)
sage: W.simple_reflection(2) # optional - chevie
(1,4)(2,17)(3,6)(5,7)(9,11)(10,12)(14,15)(16,19)(18,21)(20,22)(24,26)(25,27)(29,30)
sage: W.simple_reflection(3) # optional - chevie
(2,6)(3,18)(4,8)(5,9)(7,10)(11,12)(13,14)(17,21)(19,23)(20,24)(22,25)(26,27)(28,29)
sage: W.reflection(4)        # optional - chevie
(1,5)(2,22)(3,11)(4,19)(7,17)(8,12)(9,13)(10,15)(16,20)(18,26)(23,27)(24,28)(25,30)
sage: W.reflection(5)        # optional - chevie
(1,22)(2,4)(3,9)(5,20)(6,13)(7,16)(8,14)(12,15)(17,19)(18,24)(21,28)(23,29)(27,30)
sage: W.reflection(6)        # optional - chevie
(1,8)(2,18)(3,17)(5,12)(6,21)(7,11)(9,10)(13,15)(16,23)(20,27)(22,26)(24,25)(28,30)
```

sage.combinat.root_system.coxeter_group.**is_chevie_available**()

Tests whether the GAP3 Chevie package is available

EXAMPLES:

```
sage: from sage.combinat.root_system.coxeter_group import is_chevie_available
sage: is_chevie_available() # random
False
sage: is_chevie_available() in [True, False]
True
```

5.1.199 Coxeter Matrices

class sage.combinat.root_system.coxeter_matrix.**CoxeterMatrix**(*parent*, *data*, *coxeter_type*, *index_set*)

Bases: sage.combinat.root_system.coxeter_type.CoxeterType

A Coxeter matrix.

A Coxeter matrix $M = (m_{ij})_{i,j \in I}$ is a matrix encoding a Coxeter system (W, S), where the relations are given by $(s_i s_j)^{m_{ij}}$. Thus M is symmetric and has entries in $\{1, 2, 3, \ldots, \infty\}$ with $m_{ij} = 1$ if and only if $i = j$.

We represent $m_{ij} = \infty$ by any number $m_{ij} \leq -1$. In particular, we can construct a bilinear form $B = (b_{ij})_{i,j \in I}$ from M by

$$b_{ij} = \begin{cases} m_{ij} & m_{ij} < 0 \text{ (i.e., } m_{ij} = \infty), \\ -\cos\left(\frac{\pi}{m_{ij}}\right) & \text{otherwise.} \end{cases}$$

EXAMPLES:

```
sage: CoxeterMatrix(['A', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
sage: CoxeterMatrix(['B', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: CoxeterMatrix(['C', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: CoxeterMatrix(['D', 4])
[1 3 2 2]
[3 1 3 3]
[2 3 1 2]
[2 3 2 1]

sage: CoxeterMatrix(['E', 6])
[1 2 3 2 2 2]
[2 1 2 3 2 2]
[3 2 1 3 2 2]
[2 3 3 1 3 2]
[2 2 2 3 1 3]
[2 2 2 2 3 1]

sage: CoxeterMatrix(['F', 4])
[1 3 2 2]
[3 1 4 2]
[2 4 1 3]
[2 2 3 1]

sage: CoxeterMatrix(['G', 2])
[1 6]
[6 1]
```

By default, entries representing ∞ are given by -1 in the Coxeter matrix:

```
sage: G = Graph([(0,1,None), (1,2,4), (0,2,oo)])
sage: CoxeterMatrix(G)
[ 1  3 -1]
[ 3  1  4]
[-1  4  1]
```

It is possible to give a number ≤ -1 to represent an infinite label:

```
sage: CoxeterMatrix([[1,-1],[-1,1]])
[ 1 -1]
[-1  1]
```

```
sage: CoxeterMatrix([[1,-3/2],[-3/2,1]])
[   1 -3/2]
[-3/2    1]
```

bilinear_form(*R=None*)

Return the bilinear form of `self`.

EXAMPLES:

```
sage: CoxeterType(['A', 2, 1]).bilinear_form()
[   1 -1/2 -1/2]
[-1/2    1 -1/2]
[-1/2 -1/2    1]
sage: CoxeterType(['H', 3]).bilinear_form()
[                     1                     -1/2                                0]
[                  -1/2                        1 1/2*E(5)^2 + 1/2*E(5)^3]
[                     0 1/2*E(5)^2 + 1/2*E(5)^3                                1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1 -1 -1]
[-1  1 -1]
[-1 -1  1]
```

coxeter_graph()

Return the Coxeter graph of `self`.

EXAMPLES:

```
sage: C = CoxeterMatrix(['A',3])
sage: C.coxeter_graph()
Graph on 3 vertices

sage: C = CoxeterMatrix([['A',3],['A',1]])
sage: C.coxeter_graph()
Graph on 4 vertices
```

coxeter_matrix()

Return the Coxeter matrix of `self`.

EXAMPLES:

```
sage: CoxeterMatrix(['C',3]).coxeter_matrix()
[1 3 2]
[3 1 4]
[2 4 1]
```

coxeter_type()

Return the Coxeter type of `self` or `self` if unknown.

EXAMPLES:

```
sage: C = CoxeterMatrix(['A',4,1])
sage: C.coxeter_type()
Coxeter type of ['A', 4, 1]
```

If the Coxeter type is unknown:

```
sage: C = CoxeterMatrix([[1,3,4], [3,1,-1], [4,-1,1]])
sage: C.coxeter_type()
[ 1  3  4]
```

```
[ 3  1 -1]
[ 4 -1  1]
```

index_set()
Return the index set of `self`.

EXAMPLES:

```
sage: C = CoxeterMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CoxeterMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```

is_affine()
Return if `self` is an affine type or `False` if unknown.

EXAMPLES:

```
sage: M = CoxeterMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CoxeterMatrix([[1, 3],[3,1]])
sage: M.is_affine()
False
sage: M = CoxeterMatrix([[1, -1, 7], [-1, 1, 3], [7, 3, 1]])
sage: M.is_affine()
False
```

is_crystallographic()
Return if `self` is crystallographic.

A Coxeter matrix is crystallographic if all non-diagonal entries are either 2, 4, or 6.

EXAMPLES:

```
sage: CoxeterMatrix(['F',4]).is_crystallographic()
True
sage: CoxeterMatrix(['H',3]).is_crystallographic()
False
```

is_finite()
Return if `self` is a finite type or `False` if unknown.

EXAMPLES:

```
sage: M = CoxeterMatrix(['C',4])
sage: M.is_finite()
True
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_finite()
False
sage: M = CoxeterMatrix([[1, -1], [-1, 1]])
sage: M.is_finite()
False
```

is_simply_laced()
Return if `self` is simply-laced.

A Coxeter matrix is simply-laced if all non-diagonal entries are either 2 or 3.

EXAMPLES:
```
sage: cm = CoxeterMatrix([[1,3,3,3], [3,1,3,3], [3,3,1,3], [3,3,3,1]])
sage: cm.is_simply_laced()
True
```

rank()
Return the rank of `self`.

EXAMPLES:
```
sage: CoxeterMatrix(['C',3]).rank()
3
sage: CoxeterMatrix(["A2","B2","F4"]).rank()
8
```

relabel(*relabelling*)
Return a relabelled copy of this Coxeter matrix.

INPUT:

- `relabelling` – a function (or dictionary)

OUTPUT:

an isomorphic Coxeter type obtained by relabelling the nodes of the Coxeter graph. Namely, the node with label `i` is relabelled `f(i)` (or, by `f[i]` if `f` is a dictionary).

EXAMPLES:
```
sage: CoxeterMatrix(['F',4]).relabel({ 1:2, 2:3, 3:4, 4:1})
[1 4 2 3]
[4 1 3 2]
[2 3 1 2]
[3 2 2 1]
sage: CoxeterMatrix(['F',4]).relabel(lambda x: x+1 if x<4 else 1)
[1 4 2 3]
[4 1 3 2]
[2 3 1 2]
[3 2 2 1]
```

classmethod samples(*finite=None*, *affine=None*, *crystallographic=None*, *higher_rank=None*)
Return a sample of the available Coxeter types.

INPUT:

- `finite` – (default: `None`) a boolean or `None`
- `affine` – (default: `None`) a boolean or `None`
- `crystallographic` – (default: `None`) a boolean or `None`
- `higher_rank` – (default: `None`) a boolean or `None`

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families.

Here the `higher_rank` term denotes non-finite, non-affine, Coxeter groups (including hyperbolic types).

Todo

Implement the hyperbolic and compact hyperbolic in the samples.

EXAMPLES:

```
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples()]
[
Coxeter type of ['A', 1], Coxeter type of ['A', 5],

Coxeter type of ['B', 5], Coxeter type of ['D', 4],

Coxeter type of ['D', 5], Coxeter type of ['E', 6],

Coxeter type of ['E', 7], Coxeter type of ['E', 8],

Coxeter type of ['F', 4], Coxeter type of ['H', 3],

Coxeter type of ['H', 4], Coxeter type of ['I', 10],

Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],

Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],

Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],

Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],

                                                          [ 1 -1 -1]
                                                          [-1  1 -1]
Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1], [-1 -1  1],

          [ 1 -2  3  2]
[1 2 3]   [-2  1  2  3]
[2 1 7]   [ 3  2  1 -8]
[3 7 1], [ 2  3 -8  1]
]
```

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

```
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(finite=True)]
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 5], Coxeter type of ['D', 4],
 Coxeter type of ['D', 5], Coxeter type of ['E', 6],
 Coxeter type of ['E', 7], Coxeter type of ['E', 8],
 Coxeter type of ['F', 4], Coxeter type of ['H', 3],
 Coxeter type of ['H', 4], Coxeter type of ['I', 10]]

sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(affine=True)]
[Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]

sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(crystallographic=True)]
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 5], Coxeter type of ['D', 4],
 Coxeter type of ['D', 5], Coxeter type of ['E', 6],
 Coxeter type of ['E', 7], Coxeter type of ['E', 8],
```

```

```

Todo

add some reducible Coxeter types (suggestions?)

TESTS:

```
sage: for ct in CoxeterMatrix.samples(): TestSuite(ct).run()
```

sage.combinat.root_system.coxeter_matrix.**check_coxeter_matrix**(*m*)

Check if m represents a generalized Coxeter matrix and raise and error if not.

EXAMPLES:

```
sage: from sage.combinat.root_system.coxeter_matrix import check_coxeter_matrix
sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)

sage: m = matrix([[1,3],[3,1],[2,-1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: not a square matrix

sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,2]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: the matrix diagonal is not all 1

sage: m = matrix([[1,3,3],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: the matrix is not symmetric

sage: m = matrix([[1,3,1/2],[3,1,-1],[1/2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: invalid Coxeter label 1/2
```

```
sage: m = matrix([[1,3,1],[3,1,-1],[1,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: invalid Coxeter label 1
```

sage.combinat.root_system.coxeter_matrix.**coxeter_matrix**(*t*)

This was deprecated in trac ticket #17798 for CartanMatrix.

EXAMPLES:

```
sage: coxeter_matrix(['A', 4])
doctest:...: DeprecationWarning: coxeter_matrix() is deprecated. Use CoxeterMatrix() instead
See http://trac.sagemath.org/17798 for details.
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

sage.combinat.root_system.coxeter_matrix.**coxeter_matrix_as_function**(*t*)

Return the Coxeter matrix, as a function.

INPUT:

- t – a Cartan type

EXAMPLES:

```
sage: from sage.combinat.root_system.coxeter_matrix import coxeter_matrix_as_function
sage: f = coxeter_matrix_as_function(['A',4])
sage: matrix([[f(i,j) for j in range(1,5)] for i in range(1,5)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

sage.combinat.root_system.coxeter_matrix.**recognize_coxeter_type_from_matrix**(*coxeter_matrix*, *index_set*)

Return the Coxeter type of coxeter_matrix if known, otherwise return None.

EXAMPLES:

Some infinite ones:

```
sage: C = CoxeterMatrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: C.is_finite()  # indirect doctest
False
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.is_finite()  # indirect doctest
False
```

Some finite ones:

```
sage: m = matrix(CoxeterMatrix(['D', 4]))
sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True
sage: m = matrix(CoxeterMatrix(['H', 4]))
sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True
```

```
sage: CoxeterMatrix(CoxeterType(['A',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10]
sage: CoxeterMatrix(CoxeterType(['B',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10]
sage: CoxeterMatrix(CoxeterType(['C',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10]
sage: CoxeterMatrix(CoxeterType(['D',10]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10]
sage: CoxeterMatrix(CoxeterType(['E',6]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6]
sage: CoxeterMatrix(CoxeterType(['E',7]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 7]
sage: CoxeterMatrix(CoxeterType(['E',8]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8]
sage: CoxeterMatrix(CoxeterType(['F',4]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4]
sage: CoxeterMatrix(CoxeterType(['G',2]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2]
sage: CoxeterMatrix(CoxeterType(['H',3]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 3]
sage: CoxeterMatrix(CoxeterType(['H',4]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 4]
sage: CoxeterMatrix(CoxeterType(['I',100]).coxeter_graph()).coxeter_type()
Coxeter type of ['I', 100]
```

Some affine graphs:

```
sage: CoxeterMatrix(CoxeterType(['A',1,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 1, 1]
sage: CoxeterMatrix(CoxeterType(['A',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10, 1]
sage: CoxeterMatrix(CoxeterType(['B',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10, 1]
sage: CoxeterMatrix(CoxeterType(['C',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['C', 10, 1]
sage: CoxeterMatrix(CoxeterType(['D',10,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10, 1]
sage: CoxeterMatrix(CoxeterType(['E',6,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6, 1]
sage: CoxeterMatrix(CoxeterType(['E',7,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 7, 1]
sage: CoxeterMatrix(CoxeterType(['E',8,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8, 1]
sage: CoxeterMatrix(CoxeterType(['F',4,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4, 1]
sage: CoxeterMatrix(CoxeterType(['G',2,1]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2, 1]
```

TESTS:

Check that we detect relabellings:

```
sage: M = CoxeterMatrix([[1,2,3],[2,1,6],[3,6,1]], index_set=['a', 'b', 'c'])
sage: M.coxeter_type()
Coxeter type of ['G', 2, 1] relabelled by {0: 'a', 1: 'b', 2: 'c'}

sage: from sage.combinat.root_system.coxeter_matrix import recognize_coxeter_type_from_matrix
sage: for C in CoxeterMatrix.samples():
....:     relabelling_perm = Permutations(C.index_set()).random_element()
```

```
....:     relabelling_dict = {C.index_set()[i]: relabelling_perm[i] for i in range(C.rank())}
....:     relabeled_matrix = C.relabel(relabelling_dict)._matrix
....:     recognized_type = recognize_coxeter_type_from_matrix(relabeled_matrix, relabelling_per
....:     if C.is_finite() or C.is_affine():
....:         assert recognized_type == C.coxeter_type()
```

5.1.200 Coxeter Types

class sage.combinat.root_system.coxeter_type.**CoxeterType**

Bases: sage.structure.sage_object.SageObject

Abstract class for Coxeter types.

bilinear_form(*R=None*)

Return the bilinear form over R associated to self.

INPUT:

- R – (default: universal cyclotomic field) a ring used to compute the bilinear form

EXAMPLES:

```
sage: CoxeterType(['A', 2, 1]).bilinear_form()
[   1 -1/2 -1/2]
[-1/2    1 -1/2]
[-1/2 -1/2    1]
sage: CoxeterType(['H', 3]).bilinear_form()
[                      1                      -1/2                                0]
[                   -1/2                         1 1/2*E(5)^2 + 1/2*E(5)^3]
[                      0 1/2*E(5)^2 + 1/2*E(5)^3                                1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1 -1 -1]
[-1  1 -1]
[-1 -1  1]
```

coxeter_graph()

Return the Coxeter graph associated to self.

EXAMPLES:

```
sage: CoxeterType(['A', 3]).coxeter_graph()
Graph on 3 vertices
sage: CoxeterType(['A', 3, 1]).coxeter_graph()
Graph on 4 vertices
```

coxeter_matrix()

Return the Coxeter matrix associated to self.

EXAMPLES:

```
sage: CoxeterType(['A', 3]).coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
sage: CoxeterType(['A', 3, 1]).coxeter_matrix()
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]
```

index_set()

Return the index set for `self`.

This is the list of the nodes of the associated Coxeter graph.

EXAMPLES:

```
sage: CoxeterType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 6, 2]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 6, 2]).index_set()
(0, 1, 2, 3, 4, 5)
sage: CoxeterType(['E', 6, 1]).index_set()
(0, 1, 2, 3, 4, 5, 6)
sage: CoxeterType(['E', 6, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 2, 2]).index_set()
(0, 1)
sage: CoxeterType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CoxeterType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)
```

is_affine()

Return whether `self` is affine.

EXAMPLES:

```
sage: CoxeterType(['A', 3]).is_affine()
False
sage: CoxeterType(['A', 3, 1]).is_affine()
True
```

is_crystallographic()

Return whether `self` is crystallographic.

This returns `False` by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: [ [t, t.is_crystallographic() ] for t in CartanType.samples(finite=True) ]
[[['A', 1], True], [['A', 5], True],
 [['B', 1], True], [['B', 5], True],
 [['C', 1], True], [['C', 5], True],
 [['D', 2], True], [['D', 3], True], [['D', 5], True],
 [['E', 6], True], [['E', 7], True], [['E', 8], True],
 [['F', 4], True], [['G', 2], True],
 [['I', 5], False], [['H', 3], False], [['H', 4], False]]
```

is_finite()

Return whether `self` is finite.

EXAMPLES:

```
sage: CoxeterType(['A',4]).is_finite()
True
sage: CoxeterType(['A',4, 1]).is_finite()
False
```

is_simply_laced()

Return whether `self` is simply laced.

This returns `False` by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: [ [t, t.is_simply_laced() ] for t in CartanType.samples() ]
[[['A', 1], True], [['A', 5], True],
 [['B', 1], True], [['B', 5], False],
 [['C', 1], True], [['C', 5], False],
 [['D', 2], True], [['D', 3], True], [['D', 5], True],
 [['E', 6], True], [['E', 7], True], [['E', 8], True],
 [['F', 4], False], [['G', 2], False],
 [['I', 5], False], [['H', 3], False], [['H', 4], False],
 [['A', 1, 1], False], [['A', 5, 1], True],
 [['B', 1, 1], False], [['B', 5, 1], False],
 [['C', 1, 1], False], [['C', 5, 1], False],
 [['D', 3, 1], True], [['D', 5, 1], True],
 [['E', 6, 1], True], [['E', 7, 1], True], [['E', 8, 1], True],
 [['F', 4, 1], False], [['G', 2, 1], False],
 [['BC', 1, 2], False], [['BC', 5, 2], False],
 [['B', 5, 1]^*, False], [['C', 4, 1]^*, False],
 [['F', 4, 1]^*, False], [['G', 2, 1]^*, False],
 [['BC', 1, 2]^*, False], [['BC', 5, 2]^*, False]]
```

rank()

Return the rank of `self`.

This is the number of nodes of the associated Coxeter graph.

EXAMPLES:

```
sage: CoxeterType(['A', 4]).rank()
4
sage: CoxeterType(['A', 7, 2]).rank()
5
sage: CoxeterType(['I', 8]).rank()
2
```

classmethod samples(*finite=None*, *affine=None*, *crystallographic=None*)

Return a sample of the available Coxeter types.

INPUT:

- `finite` – a boolean or `None` (default: `None`)
- `affine` – a boolean or `None` (default: `None`)
- `crystallographic` – a boolean or `None` (default: `None`)

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families.

EXAMPLES:

```
sage: CoxeterType.samples()
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8], Coxeter type of ['F', 4],
 Coxeter type of ['H', 3], Coxeter type of ['H', 4],
 Coxeter type of ['I', 10], Coxeter type of ['A', 2, 1],
 Coxeter type of ['B', 5, 1], Coxeter type of ['C', 5, 1],
 Coxeter type of ['D', 5, 1], Coxeter type of ['E', 6, 1],
 Coxeter type of ['E', 7, 1], Coxeter type of ['E', 8, 1],
 Coxeter type of ['F', 4, 1], Coxeter type of ['G', 2, 1],
 Coxeter type of ['A', 1, 1]]
```

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

```
sage: CoxeterType.samples(finite=True)
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8], Coxeter type of ['F', 4],
 Coxeter type of ['H', 3], Coxeter type of ['H', 4],
 Coxeter type of ['I', 10]]

sage: CoxeterType.samples(affine=True)
[Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]

sage: CoxeterType.samples(crystallographic=True)
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8], Coxeter type of ['F', 4],
 Coxeter type of ['A', 2, 1], Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 5, 1], Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1], Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1], Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1], Coxeter type of ['A', 1, 1]]

sage: CoxeterType.samples(crystallographic=False)
[Coxeter type of ['H', 3],
 Coxeter type of ['H', 4],
 Coxeter type of ['I', 10]]
```

Todo

add some reducible Coxeter types (suggestions?)

TESTS:

```
sage: for ct in CoxeterType.samples(): TestSuite(ct).run()
```

class sage.combinat.root_system.coxeter_type.**CoxeterTypeFromCartanType**(*cartan_type*)

Bases: sage.combinat.root_system.coxeter_type.CoxeterType, sage.structure.unique_representation.UniqueRepresentation

A Coxeter type associated to a Cartan type.

cartan_type()

Return the Cartan type used to construct `self`.

EXAMPLES:

```
sage: C = CoxeterType(['C',3])
sage: C.cartan_type()
['C', 3]
```

coxeter_graph()

Return the Coxeter graph of `self`.

EXAMPLES:

```
sage: C = CoxeterType(['H',3])
sage: C.coxeter_graph().edges()
[(1, 2, 3), (2, 3, 5)]
```

coxeter_matrix()

Return the Coxeter matrix associated to `self`.

EXAMPLES:

```
sage: C = CoxeterType(['H',3])
sage: C.coxeter_matrix()
[1 3 2]
[3 1 5]
[2 5 1]
```

index_set()

Return the index set of `self`.

EXAMPLES:

```
sage: C = CoxeterType(['A', 4])
sage: C.index_set()
(1, 2, 3, 4)
```

is_affine()

Return if `self` is an affine type.

EXAMPLES:

```
sage: C = CoxeterType(['F', 4, 1])
sage: C.is_affine()
True
```

is_crystallographic()

Return if `self` is crystallographic.

EXAMPLES:

```
sage: C = CoxeterType(['C', 3])
sage: C.is_crystallographic()
```

```
True

sage: C = CoxeterType(['H', 3])
sage: C.is_crystallographic()
False
```

is_finite()
Return if `self` is a finite type.

EXAMPLES:

```
sage: C = CoxeterType(['E', 6])
sage: C.is_finite()
True
```

is_simply_laced()
Return if `self` is simply-laced.

EXAMPLES:

```
sage: C = CoxeterType(['A', 5])
sage: C.is_simply_laced()
True

sage: C = CoxeterType(['B', 3])
sage: C.is_simply_laced()
False
```

rank()
Return the rank of `self`.

EXAMPLES:

```
sage: C = CoxeterType(['I', 16])
sage: C.rank()
2
```

relabel(*relabelling*)
Return a relabelled copy of `self`.

EXAMPLES:

```
sage: ct = CoxeterType(['A',2])
sage: ct.relabel({1:-1, 2:-2})
Coxeter type of ['A', 2] relabelled by {1: -1, 2: -2}
```

5.1.201 Dynkin diagrams

AUTHORS:

- Travis Scrimshaw (2012-04-22): Nicolas M. Thiery moved Cartan matrix creation to here and I cached results for speed.
- Travis Scrimshaw (2013-06-11): Changed inputs of Dynkin diagrams to handle other Dynkin diagrams and graphs. Implemented remaining Cartan type methods.
- Christian Stump, Travis Scrimshaw (2013-04-11): Added Cartan matrix as possible input for Dynkin diagrams.

sage.combinat.root_system.dynkin_diagram.**DynkinDiagram**(**args*, ***kwds*)
Return the Dynkin diagram corresponding to the input.

INPUT:

The input can be one of the following:

- empty to obtain an empty Dynkin diagram
- a Cartan type
- a Cartan matrix
- a Cartan matrix and an indexing set

One can also input an indexing set by passing a tuple using the optional argument `index_set`.

The edge multiplicities are encoded as edge labels. For the corresponding Cartan matrices, this uses the convention in Hong and Kang, Kac, Fulton and Harris, and crystals. This is the **opposite** convention in Bourbaki and Wikipedia's Dynkin diagram (Wikipedia article Dynkin_diagram). That is for $i \neq j$:

```
i <--k-- j <==> a_ij = -k
           <==> -scalar(coroot[i], root[j]) = k
           <==> multiple arrows point from the longer root
                to the shorter one
```

For example, in type C_2, we have:

```
sage: C2 = DynkinDiagram(['C',2]); C2
O=<=O
1   2
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]
```

However Bourbaki would have the Cartan matrix as:

$$\begin{bmatrix} 2 & -1 \\ -2 & 2 \end{bmatrix}.$$

EXAMPLES:

```
sage: DynkinDiagram(['A', 4])
O---O---O---O
1   2   3   4
A4

sage: DynkinDiagram(['A',1],['A',1])
O
1
O
2
A1xA1

sage: R = RootSystem("A2xB2xF4")
sage: DynkinDiagram(R)
O---O
1   2
O=>=O
3   4
O---O=>=O---O
5   6   7   8
A2xB2xF4

sage: R = RootSystem("A2xB2xF4")
```

```
sage: CM = R.cartan_matrix(); CM
[ 2 -1| 0  0| 0  0  0  0]
[-1  2| 0  0| 0  0  0  0]
[-----+-----+-----------]
[ 0  0| 2 -1| 0  0  0  0]
[ 0  0|-2  2| 0  0  0  0]
[-----+-----+-----------]
[ 0  0| 0  0| 2 -1  0  0]
[ 0  0| 0  0|-1  2 -1  0]
[ 0  0| 0  0| 0 -2  2 -1]
[ 0  0| 0  0| 0  0 -1  2]
sage: DD = DynkinDiagram(CM); DD
O---O
1   2
O=>=O
3   4
O---O=>=O---O
5   6   7   8
A2xB2xF4
sage: DD.cartan_matrix()
[ 2 -1  0  0  0  0  0  0]
[-1  2  0  0  0  0  0  0]
[ 0  0  2 -1  0  0  0  0]
[ 0  0 -2  2  0  0  0  0]
[ 0  0  0  0  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0 -2  2 -1]
[ 0  0  0  0  0  0 -1  2]
```

We can also create Dynkin diagrams from arbitrary Cartan matrices:

```
sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: C.index_set()
(0, 1)
sage: CI = CartanMatrix([[2, -3], [-4, 2]], [3, 5])
sage: DI = DynkinDiagram(CI)
sage: DI.index_set()
(3, 5)
sage: CII = CartanMatrix([[2, -3], [-4, 2]])
sage: DII = DynkinDiagram(CII, ('y', 'x'))
sage: DII.index_set()
('x', 'y')
```

See also:

`CartanType()` for a general discussion on Cartan types and in particular node labeling conventions.

TESTS:

Check that trac ticket #15277 is fixed by not having edges from 0's:

```
sage: CM = CartanMatrix([[2,-1,0,0],[-3,2,-2,-2],[0,-1,2,-1],[0,-1,-1,2]])
sage: CM
[ 2 -1  0  0]
[-3  2 -2 -2]
[ 0 -1  2 -1]
[ 0 -1 -1  2]
sage: CM.dynkin_diagram().edges()
```

```
[(0, 1, 3),
 (1, 0, 1),
 (1, 2, 1),
 (1, 3, 1),
 (2, 1, 2),
 (2, 3, 1),
 (3, 1, 2),
 (3, 2, 1)]
```

class sage.combinat.root_system.dynkin_diagram.**DynkinDiagram_class**(*t=None*, *index_set=None*, ***options*)

Bases: sage.graphs.digraph.DiGraph, sage.combinat.root_system.cartan_type.CartanType_abstr

A Dynkin diagram.

See also:

DynkinDiagram()

INPUT:

- t – a Cartan type, Cartan matrix, or None

EXAMPLES:

```
sage: DynkinDiagram(['A', 3])
O---O---O
1   2   3
A3
sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: C.dynkin_diagram().cartan_matrix() == C
True
```

TESTS:

Check that the correct type is returned when copied:

```
sage: d = DynkinDiagram(['A', 3])
sage: type(copy(d))
<class 'sage.combinat.root_system.dynkin_diagram.DynkinDiagram_class'>
```

We check that trac ticket #14655 is fixed:

```
sage: cd = copy(d)
sage: cd.add_vertex(4)
sage: d.vertices() != cd.vertices()
True
```

Implementation note: if a Cartan type is given, then the nodes are initialized from the index set of this Cartan type.

add_edge(*i*, *j*, *label=1*)

EXAMPLES:

```
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
sage: d = DynkinDiagram_class(CartanType(['A',3]))
sage: list(sorted(d.edges()))
[]
sage: d.add_edge(2, 3)
```

```
sage: list(sorted(d.edges()))
[(2, 3, 1), (3, 2, 1)]
```

static an_instance()
Returns an example of Dynkin diagram

EXAMPLES:

```
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
sage: g = DynkinDiagram_class.an_instance()
sage: g
Dynkin diagram of rank 3
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2  2 -1]
[-1 -1  2]
```

cartan_matrix()
Returns the Cartan matrix for this Dynkin diagram

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

cartan_type()
EXAMPLES:

```
sage: DynkinDiagram("A2","B2","F4").cartan_type()
A2xB2xF4
```

column(j)
Returns the j^{th} column $(a_{i,j})_i$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples $(i, a_{i,j})$

EXAMPLES:

```
sage: g = DynkinDiagram(["B",4])
sage: [ (i,a) for (i,a) in g.column(3) ]
[(3, 2), (2, -1), (4, -2)]
```

dual()
Returns the dual Dynkin diagram, obtained by reversing all edges.

EXAMPLES:

```
sage: D = DynkinDiagram(['C',3])
sage: D.edges()
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: D.dual()
O---O=>=O
1   2   3
B3
sage: D.dual().edges()
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
sage: D.dual() == DynkinDiagram(['B',3])
True
```

TESTS:

```
sage: D = DynkinDiagram(['A',0]); D
A0
sage: D.edges()
[]
sage: D.dual()
A0
sage: D.dual().edges()
[]
sage: D = DynkinDiagram(['A',1])
sage: D.edges()
[]
sage: D.dual()
O
1
A1
sage: D.dual().edges()
[]
```

dynkin_diagram()

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).dynkin_diagram()
O---O=<=O
1   2   3
C3
```

index_set()

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).index_set()
(1, 2, 3)
sage: DynkinDiagram("A2","B2","F4").index_set()
(1, 2, 3, 4, 5, 6, 7, 8)
```

is_affine()

Check if `self` corresponds to an affine root system.

EXAMPLES:

```
sage: CartanType(['F',4]).dynkin_diagram().is_affine()
False
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_affine()
False
```

is_crystallographic()

Implements `CartanType_abstract.is_crystallographic()`

A Dynkin diagram always corresponds to a crystallographic root system.

EXAMPLES:

```
sage: CartanType(['F',4]).dynkin_diagram().is_crystallographic()
True
```

TESTS:

```
sage: CartanType(['G',2]).dynkin_diagram().is_crystallographic()
True
```

is_finite()

Check if `self` corresponds to a finite root system.

EXAMPLES:

```
sage: CartanType(['F',4]).dynkin_diagram().is_finite()
True
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_finite()
False
```

is_irreducible()

Check if `self` corresponds to an irreducible root system.

EXAMPLES:

```
sage: CartanType(['F',4]).dynkin_diagram().is_irreducible()
True
```

rank()

Returns the index set for this Dynkin diagram

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).rank()
3
sage: DynkinDiagram("A2","B2","F4").rank()
8
```

relabel(*relabelling*, *inplace=False*, ***kwds*)

Return the relabelling Dynkin diagram of `self`.

EXAMPLES:

```
sage: D = DynkinDiagram(['C',3])
sage: D.relabel({1:0, 2:4, 3:1})
O---O=<=O
0   4   1
C3 relabelled by {1: 0, 2: 4, 3: 1}
sage: D
O---O=<=O
1   2   3
C3
```

row(i)

Returns the i^{th} row $(a_{i,j})_j$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples $(j, a_{i,j})$

EXAMPLES:

```
sage: g = DynkinDiagram(["C",4])
sage: [ (i,a) for (i,a) in g.row(3) ]
[(3, 2), (2, -1), (4, -2)]
```

subtype(*index_set*)

Return a subtype of `self` given by `index_set`.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of `self` by `index_set`.

EXAMPLES:

```
sage: D = DynkinDiagram(['A',6,2]); D
O=<=O---O=<=O
```

```
0   1   2   3
BC3~
sage: D.subtype([1,2,3])
Dynkin diagram of rank 3
```

symmetrizer()

Return the symmetrizer of the corresponding Cartan matrix.

EXAMPLES:

```
sage: d = DynkinDiagram()
sage: d.add_edge(1,2,3)
sage: d.add_edge(2,3)
sage: d.add_edge(3,4,3)
sage: d.symmetrizer()
Finite family {1: 9, 2: 3, 3: 3, 4: 1}
```

TESTS:

We check that trac ticket #15740 is fixed:

```
sage: d = DynkinDiagram()
sage: d.add_edge(1,2,3)
sage: d.add_edge(2,3)
sage: d.add_edge(3,4,3)
sage: L = d.root_system().root_lattice()
sage: al = L.simple_roots()
sage: al[1].associated_coroot()
alphacheck[1]
sage: al[1].reflection(al[2])
alpha[1] + 3*alpha[2]
```

sage.combinat.root_system.dynkin_diagram.**precheck**(*t*, *letter=None*, *length=None*, *affine=None*, *n_ge=None*, *n=None*)

EXAMPLES:

```
sage: from sage.combinat.root_system.dynkin_diagram import precheck
sage: ct = CartanType(['A',4])
sage: precheck(ct, letter='C')
Traceback (most recent call last):
...
ValueError: t[0] must be = 'C'
sage: precheck(ct, affine=1)
Traceback (most recent call last):
...
ValueError: t[2] must be = 1
sage: precheck(ct, length=3)
Traceback (most recent call last):
...
ValueError: len(t) must be = 3
sage: precheck(ct, n=3)
Traceback (most recent call last):
...
ValueError: t[1] must be = 3
sage: precheck(ct, n_ge=5)
Traceback (most recent call last):
...
ValueError: t[1] must be >= 5
```

5.1.202 Hecke algebra representations

class sage.combinat.root_system.hecke_algebra_representation.**CherednikOperatorsEigenvectors**(*T*, *T*, *n*, *n*, *i*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A class for the family of eigenvectors of the Y Cherednik operators for a module over a (Double) Affine Hecke algebra

INPUT:

- `T` – a family $(T_i)_{i\in I}$ implementing the action of the generators of an affine Hecke algebra on `self`. The intertwiner operators are built from these.
- `T_Y` – a family $(T_i^Y)_{i\in I}$ implementing the action of the generators of an affine Hecke algebra on `self`. By default, this is `T`. But this can be used to get the action of the full Double Affine Hecke Algebra. The Y operators are built from the `T_Y`.

This returns a function $\mu \mapsto E_\mu$ which uses intertwining operators to calculate recursively eigenvectors E_μ for the action of the torus of the affine Hecke algebra with eigenvalue given by f. Namely:

$$E_\mu.Y^{\lambda^\vee} = f(\lambda^\vee, \mu)E_\mu$$

Assumptions:

- `seed(mu)` initializes the recurrence by returning an appropriate eigenvector E_μ for μ trivial enough. For example, for nonsymmetric Macdonald polynomials `seed(mu)` returns the monomial X^μ for a minuscule weight μ.
- f is almost equivariant. Namely, $f(\lambda^\vee, \mu) = f(\lambda^\vee s_i, twist(\mu, i))$ whenever i is a descent of μ.
- $twist(\mu, i)$ maps μ closer to the dominant chamber whenever i is a descent of μ.

Todo

Add tests for the above assumptions, and also that the classical operators $T_1, \ldots, T_n$ from T and T_Y coincide.

Y()

Return the Cherednik operators.

EXAMPLES:

```
sage: W = WeylGroup(["B",2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['B', 2, 1]}
```

affine_lift(*mu*)

Lift the index `\mu` to a space admitting an action of the affine Weyl group.

INPUT:

- `mu` – an element μ of the indexing set

In this space, one should have `first_descent` and `apply_simple_reflection` act properly.

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_lift(w)
121
```

affine_retract(*mu*)

Retract μ from a space admitting an action of the affine Weyl group.

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_retract(E.affine_lift(w)) == w
True
```

cartan_type()

Return Cartan type of `self`.

EXAMPLES:

```
sage: W = WeylGroup(["B",3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.cartan_type()
['B', 3, 1]

sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).cartan_type()
['B', 2, 1]
```

domain()

The module on which the affine Hecke algebra acts.

EXAMPLES:

```
sage: W = WeylGroup(["B",3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.domain()
Group algebra of Weyl Group of type ['B', 3] (as a matrix group acting on the ambient space)
```

eigenvalue(*mu*, *l*)

Return the eigenvalue of $Y_{\lambda^\vee}$ on E_μ computed by applying $Y_{\lambda^\vee}$ on E_μ.

INPUT:

- mu – the index μ of an eigenvector, or a tentative eigenvector
- l – the index $\lambda^\vee$ of a Cherednik operator in self.Y_index_set()

This default implementation applies explicitly Y_μ to E_λ.

EXAMPLES:

```
sage: W = WeylGroup(["B",2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: Y = E.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: E.eigenvalue(w0, alphacheck[1])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[2])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[0])
q2^2/q1^2
```

The following checks that all E_w are eigenvectors, with eigenvalue given by Lemma 7.5 of [HST2008] (checked for A_2, A_3):

```
sage: Pcheck = Y.keys()
sage: Wcheck = Pcheck.weyl_group()
sage: P0check = Pcheck.classical()
sage: def height(root):
....:     return sum(P0check(root).coefficients())
sage: def eigenvalue(w, mu):
....:     return (-q2/q1)^height(Wcheck.from_reduced_word(w.reduced_word()).action(mu))
sage: all(E.eigenvalue(w, a) == eigenvalue(w, a) for w in E.keys() for a in Y.keys().simple_
True
```

eigenvalues(*mu*)

Return the eigenvalues of $Y_{\alpha_0}, \ldots, Y_{\alpha_n}$ on E_μ.

INPUT:

- mu – the index μ of an eigenvector or a tentative eigenvector

EXAMPLES:

```
sage: W = WeylGroup(["B",2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: E.eigenvalues(w0)
[q2^2/q1^2, q1/(-q2), q1/(-q2)]
sage: w = W.an_element()
sage: E.eigenvalues(w)
[(-q2)/q1, (-q2^2)/(-q1^2), q1^3/(-q2^3)]
```

hecke_parameters(*i*)

Return the Hecke parameters for index i.

EXAMPLES:

```
sage: W = WeylGroup(["B",3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: E.hecke_parameters(1)
(q1, q2)
sage: E.hecke_parameters(2)
(q1, q2)
sage: E.hecke_parameters(0)
(q1, q2)
```

keys()

The index set for the eigenvectors.

By default, this assumes that the eigenvectors span the full affine Hecke algebra module and that the eigenvectors have the same indexing as the basis of this module.

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.keys()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
```

recursion(*mu*)

Return the indices used in the recursion.

INPUT:

- mu – the index μ of an eigenvector

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: E.recursion(w0)
[]
sage: w = W.an_element(); w
123
sage: E.recursion(w)
[1, 2, 1]
```

seed(*mu*)

Return the eigenvector for μ minuscule.

INPUT:

- mu – an element μ of the indexing set

OUTPUT: an element of `T.domain()`

This default implementation returns the monomial indexed by μ.

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.seed(W.long_element())
B[123121]
```

twist (*mu*, *i*)

Act by s_i on μ.

By default, this calls the method `apply_simple_reflection`.

EXAMPLES:

```
sage: W = WeylGroup(["B",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231
```

class sage.combinat.root_system.hecke_algebra_representation.**HeckeAlgebraRepresentation**(*domain*, *on_basis*, *cartan_type*, *q1*, *q2*, *q=1*, *side='r*

Bases: `sage.misc.fast_methods.WithEqualityById`, `sage.structure.sage_object.SageObject`

A representation of an (affine) Hecke algebra given by the action of the T generators

Let F_i be a family of operators implementing an action of the operators $(T_i)_{i\in I}$ of the Hecke algebra on some vector space `domain`, given by their action on the basis of `domain`. This constructs the family of operators $(F_w)_{w\in W}$ describing the action of all elements of the basis $(T_w)_{w\in W}$ of the Hecke algebra. This is achieved by linearity on the first argument, and applying recursively the F_i along a reduced word for $w = s_{i_1}\cdots s_{i_k}$:

$$F_w(x) = F_{i_k} \circ \cdots \circ F_{i_1}(x).$$

INPUT:

- `domain` – a vector space
- `f` – a function `f(l,i)` taking a basis element l of `domain` and an index i, and returning F_i
- `cartan_type` – The Cartan type of the Hecke algebra
- `q1,q2` – The eigenvalues of the generators T of the Hecke algebra
- `side` – "left" or "right" (default: "right") whether this is a left or right representation

EXAMPLES:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(["A",3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2); H
A representation of the (q1, q2)-Hecke algebra of type ['A', 3, 1]
on Group algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
```

Among other things, it implements the T_w operators, their inverses and compositions thereof:

```
sage: H.Tw((1,2))
Generic endomorphism of Group algebra of Weyl Group of type ['A', 3] (as a matrix group acting c
```

and the Cherednik operators $Y^{\lambda^\vee}$:

```
sage: H.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['A', 3, 1]}
```

TESTS:

```
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentat
sage: W = SymmetricGroup(3)
sage: domain = W.algebra(QQ)
sage: action = lambda x,i: domain.monomial(x.apply_simple_reflection(i, side="right"))
sage: r = HeckeAlgebraRepresentation(domain, action, CartanType(["A",2]), 1, -1)
sage: hash(r) # random
3
```

REFERENCES:

Ti_inverse_on_basis(x, i)

The T_i^{-1} operators, on basis elements

INPUT:

- `x` – the index of a basis element
- `i` – the index of a generator

EXAMPLES:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_inverse_on_basis(w, 1)
-1/q2*B[1231] + ((q1+q2)/(q1*q2))*B[123]
```

Ti_on_basis(x, i)

The T_i operators, on basis elements.

INPUT:

- `x` – the index of a basis element
- `i` – the index of a generator

EXAMPLES:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element()
sage: rho.Ti_on_basis(w,1)
q1*B[1231]
```

Tw(*word*, *signs=None*, *scalar=None*)

Return T_w.

INPUT:

- `word` – a word $i_1, \ldots, i_k$ for some element w of the Weyl group. See `straighten_word()` for how this word can be specified.
- `signs` – a list $\epsilon_1, \ldots, \epsilon_k$ of the same length as `word` with $\epsilon_i = \pm 1$ or `None` for $1, \ldots, 1$ (default: `None`)
- `scalar` – an element c of the base ring or `None` for 1 (default: `None`)

OUTPUT:

a module morphism implementing

$$T_w = T_{i_k} \circ \cdots \circ T_{i_1}$$

in left action notation; that is T_{i_1} is applied first, then T_{i_2}, etc.

More generally, if `scalar` or `signs` is specified, the morphism implements

$$cT_{i_k}^{\epsilon_k} \circ \cdots \circ T_{i_1}^{\epsilon_k}$$

EXAMPLES:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: x = KW.an_element(); x
2*B[12321] + 3*B[1231] + B[123] + B[]

sage: T = KW.demazure_lusztig_operators(q1,q2)
sage: T12 = T.Tw( (1,2) )
sage: T12(KW.one())
q1^2*B[12]
```

This is $T_2 \circ T_1$:

```
sage: T[2](T[1](KW.one()))
q1^2*B[12]
sage: T[1](T[2](KW.one()))
q1^2*B[21]
sage: T12(x) == T[2](T[1](x))
True
```

Now with signs and scalar coefficient we construct $3T_2 \circ T_1^{-1}$:

```
sage: phi = T.Tw((1,2), (-1,1), 3)
sage: phi(KW.one())
((-3*q1)/q2)*B[12] + ((3*q1+3*q2)/q2)*B[2]
sage: phi(T[1](x)) == 3*T[2](x)
True
```

For debugging purposes, one can recover the input data:

```
sage: phi.word
(1, 2)
sage: phi.signs
(-1, 1)
sage: phi.scalar
3
```

Tw_inverse(*word*)

Return T_w^{-1}.

This is essentially a shorthand for `Tw()` with all minus signs.

Todo

Add an example where $T_i \neq T_i^{-1}$

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_ = lambda x: "".join(str(i) for i in x.reduced_word())
sage: KW = W.algebra(QQ)
sage: rho = KW.demazure_lusztig_operators(1, -1)
sage: x = KW.monomial(W.an_element()); x
B[123]
sage: word = [1,2]
sage: rho.Tw(word)(x)
B[12312]
sage: rho.Tw_inverse(word)(x)
B[12321]

sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2)
sage: x = KW.monomial(W.an_element()); x
B[123]
sage: rho.Tw_inverse(word)(x)
1/q2^2*B[12321] + ((-q1-q2)/(q1*q2^2))*B[1231] + ((-q1-q2)/(q1*q2^2))*B[1232] + ((q1^2+2*q1*
sage: rho.Tw(word)(_)
B[123]
```

Y(*base_ring=Integer Ring*)

Return the Cherednik operators Y for this representation of an affine Hecke algebra.

INPUT:

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

This is a family of operators indexed by the coroot lattice for this Cartan type. In practice this is currently indexed instead by the affine coroot lattice, even if this indexing is not one to one, in order to allow for

$Y[\alpha_0^\vee]$.

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: Y = rho.Y(); Y
Lazy family (...(i))_{i in Coroot lattice of the Root system of type ['A', 3, 1]}
```

Y_eigenvectors()

Return the family of eigenvectors for the Cherednik operators Y of this representation of an affine Hecke algebra.

INPUT:

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

EXAMPLES:

```
sage: W = WeylGroup(["B",2])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = rho.Y_eigenvectors()
sage: E.keys()
Weyl Group of type ['B', 2] (as a matrix group acting on the ambient space)
sage: w0 = W.long_element()
```

To set the recurrence up properly, one often needs to customize the `CherednikOperatorsEigenvectors.affine_lift()` and `CherednikOperatorsEigenvectors.affine_retract()` methods. This would usually be done by subclassing `CherednikOperatorsEigenvectors`; here we just override the methods directly.

In this particular case, we multiply by w_0 to take into account that w_0 is the seed for the recursion:

```
sage: E.affine_lift = w0._mul_
sage: E.affine_retract = w0._mul_

sage: E[w0]
B[2121]
sage: E.eigenvalues(E[w0])
[q2^2/q1^2, q1/(-q2), q1/(-q2)]
```

This step is taken care of automatically if one instead calls the specialization `sage.coxeter_groups.CoxeterGroups.Algebras.demazure_lusztig_eigenvectors()`.

Now we can compute all eigenvectors:

```
sage: [E[w] for w in W]
[B[2121] - B[121] - B[212] + B[12] + B[21] - B[1] - B[2] + B[],
-B[2121] + B[212],
(q2/(q1-q2))*B[2121] + (q2/(-q1+q2))*B[121] + (q2/(-q1+q2))*B[212] - B[12] + ((-q2)/(-q1+q2)
((-q2^2)/(-q1^2+q1*q2-q2^2))*B[2121] - B[121] + (q2^2/(-q1^2+q1*q2-q2^2))*B[212] + B[21],
((q1^2+q2^2)/(-q1^2+q1*q2-q2^2))*B[2121] + ((-q1^2-q2^2)/(-q1^2+q1*q2-q2^2))*B[121] + ((-q2^
```

```
B[2121],
(q2/(-q1+q2))*B[2121] + ((-q2)/(-q1+q2))*B[121] - B[212] + B[12],
-B[2121] + B[121]]
```

Y_lambdacheck(*lambdacheck*)

Return the Cherednik operators $Y^{\lambda^\vee}$ for this representation of an affine Hecke algebra.

INPUT:

- `lambdacheck` – an element of the coroot lattice for this cartan type

EXAMPLES:

```
sage: W = WeylGroup(["B",2])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
```

We take q_2 and q_1 as eigenvalues to match with the notations of [HST2008]

```
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: L = rho.Y().keys()
sage: alpha = L.simple_roots()
sage: Y0 = rho.Y_lambdacheck(alpha[0])
sage: Y1 = rho.Y_lambdacheck(alpha[1])
sage: Y2 = rho.Y_lambdacheck(alpha[2])

sage: x = KW.monomial(W.an_element()); x
B[12]
sage: Y1(x)
((-q1^2-2*q1*q2-q2^2)/(-q2^2))*B[2121] + ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1*q2^2))*B[121] + (
sage: Y2(x)
((-q1^4-q1^3*q2-q1*q2^3-q2^4)/(-q1^3*q2))*B[2121] + ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1^2*q2))
sage: Y1(Y2(x))
((q1*q2+q2^2)/q1^2)*B[212] + ((-q2)/q1)*B[12]
sage: Y2(Y1(x))
((q1*q2+q2^2)/q1^2)*B[212] + ((-q2)/q1)*B[12]
```

The Y operators commute:

```
sage: Y0(Y1(x)) - Y1(Y0(x))
0
sage: Y2(Y1(x)) - Y1(Y2(x))
0
```

In the classical root lattice, $\alpha_0 + \alpha_1 + \alpha_2 = 0$:

```
sage: Y0(Y1(Y2(x)))
B[12]
```

Lemma 7.2 of [HST2008]:

```
sage: w0 = KW.monomial(W.long_element())
sage: rho.Tw(0)(w0)
q2*B[1]
sage: rho.Tw_inverse(1)(w0)
1/q2*B[212]
sage: rho.Tw_inverse(2)(w0)
1/q2*B[121]
```

Lemma 7.5 of [HST2008]:

```
sage: Y0(w0)
q1^2/q2^2*B[2121]
sage: Y1(w0)
(q2/(-q1))*B[2121]
sage: Y2(w0)
(q2/(-q1))*B[2121]
```

Todo

Add more tests

Add tests in type BC affine where the null coroot $\delta^\vee$ can have non trivial coefficient in term of α_0

See also:

- [HST2008] for the formula in terms of q_1, q_2

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation
sage: KW = SymmetricGroup(3).algebra(QQ)
sage: action = lambda x,i: KW.monomial(x.apply_simple_reflection(i, side="right"))
sage: H = HeckeAlgebraRepresentation(KW, action, CartanType(["A",2]), 1, -1)
sage: H.cartan_type()
['A', 2]

sage: H = WeylGroup(["A",3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.cartan_type()
['A', 3, 1]
```

domain()

Return the domain of `self`.

EXAMPLES:

```
sage: H = WeylGroup(["A",3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.domain()
Group algebra of Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
```

on_basis(*x*, *word*, *signs=None*, *scalar=None*)

Action of product of T_i and T_i^{-1} on `x`.

INPUT:

- `x` – the index of a basis element
- `word` – word of indices of generators
- `signs` – (default: None) sequence of signs of same length as `word`; determines which operators are supposed to be taken as inverses.
- `scalar` – (default: None) scalar to multiply the answer by

EXAMPLES:

```
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation
sage: W = SymmetricGroup(3)
```

```
sage: domain = W.algebra(QQ)
sage: action = lambda x,i: domain.monomial(x.apply_simple_reflection(i, side="right"))
sage: rho = HeckeAlgebraRepresentation(domain, action, CartanType(["A",2]), 1, -1)

sage: rho.on_basis(W.one(), (1,2,1))
(1,3)

sage: word = (1,2)
sage: u = W.from_reduced_word(word)
sage: for w in W:  assert rho.on_basis(w, word) == domain.monomial(w*u)
```

The next example tests the signs:

```
sage: W = WeylGroup("A3")
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element(); w
123
sage: rho.on_basis(w, (1,),  signs=(-1,))
-1/q2*B[1231] + ((q1+q2)/(q1*q2))*B[123]
sage: rho.on_basis(w, (1,),  signs=( 1,))
q1*B[1231]
sage: rho.on_basis(w, (1,1), signs=(1,-1))
B[123]
sage: rho.on_basis(w, (1,1), signs=(-1,1))
B[123]
```

parameters(*i*)

Return q_1, q_2 such that $(T_i - q_1)(T_i - q_2) = 0$.

EXAMPLES:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(["A",3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2)
sage: H.parameters(1)
(q1, q2)

sage: H = KW.demazure_lusztig_operators(1,-1)
sage: H.parameters(1)
(1, -1)
```

Todo

At this point, this method is constant. It's meant as a starting point for implementing parameters depending on the node i of the Dynkin diagram.

---

straighten_word(*word*)

Return a tuple of indices of generators after some straightening.

INPUT:

- `word` – a list/tuple of indices of generators, the index of a generator, or an object with a reduced word method

OUTPUT: a tuple of indices of generators

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: H = W.algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.straighten_word(1)
(1,)
sage: H.straighten_word((2,1))
(2, 1)
sage: H.straighten_word([2,1])
(2, 1)
sage: H.straighten_word(W.an_element())
(1, 2, 3)
```

5.1.203 Integrable Representations of Affine Lie Algebras

class sage.combinat.root_system.integrable_representations.**IntegrableRepresentation**(*Lam*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.category_object.CategoryObject

An irreducible integrable highest weight representation of an affine Lie algebra.

INPUT:

- Lam – a dominant weight in an extended weight lattice of affine type

REFERENCES:

If Λ is a dominant integral weight for an affine root system, there exists a unique integrable representation $V = V_\Lambda$ of highest weight Λ. If μ is another weight, let $m(\mu)$ denote the multiplicity of the weight μ in this representation. The set $\mathrm{supp}(V)$ of μ such that $m(\mu) > 0$ is contained in the paraboloid

$$(\Lambda + \rho|\Lambda + \rho) - (\mu + \rho|\mu + \rho) \geq 0$$

where $(\,|\,)$ is the invariant inner product on the weight lattice and ρ is the Weyl vector. Moreover if $m(\mu) > 0$ then $\mu \in \mathrm{supp}(V)$ differs from Λ by an element of the root lattice ([Kac], Propositions 11.3 and 11.4).

Let δ be the nullroot, which is the lowest positive imaginary root. Then by [Kac], Proposition 11.3 or Corollary 11.9, for fixed μ the function $m(\mu - k\delta)$ is a monotone increasing function of k. It is useful to take μ to be such that this function is nonzero if and only if $k \geq 0$. Therefore we make the following definition. If μ is such that $m(\mu) \neq 0$ but $m(\mu + \delta) = 0$ then μ is called *maximal*.

Since δ is fixed under the action of the affine Weyl group, and since the weight multiplicities are Weyl group invariant, the function $k \mapsto m(\mu - k\delta)$ is unchanged if μ is replaced by an equivalent weight. Therefore in tabulating these functions, we may assume that μ is dominant. There are only a finite number of dominant maximal weights.

Since every nonzero weight multiplicity appears in the string $\mu - k\delta$ for one of the finite number of dominant maximal weights μ, it is important to be able to compute these. We may do this as follows.

EXAMPLES:

```
sage: Lambda = RootSystem(['A',3,1]).weight_lattice(extended=true).fundamental_weights()
sage: IntegrableRepresentation(Lambda[1]+Lambda[2]+Lambda[3]).print_strings()
2*Lambda[0] + Lambda[2]: 4 31 161 665 2380 7658 22721 63120 166085 417295 1007601 2349655
Lambda[0] + 2*Lambda[1]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884 1779570
Lambda[0] + 2*Lambda[3]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884 1779570
Lambda[1] + Lambda[2] + Lambda[3]: 1 10 60 274 1056 3601 11199 32354 88009 227555 563390 1343178
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 310056 757056 1783324
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).fundamental_weights()
```

```
sage: IntegrableRepresentation(Lambda[0]+Lambda[1]).print_strings()                    # lon
Lambda[0] + Lambda[1]: 1 10 62 293 1165 4097 13120 38997 109036 289575 735870 1799620
Lambda[3] + Lambda[4] - delta: 3 25 136 590 2205 7391 22780 65613 178660 463842 1155717 2777795
```

In this example, we construct the extended weight lattice of Cartan type $A_3^{(1)}$, then define `Lambda` to be the fundamental weights $(\Lambda_i)_{i\in I}$. We find there are 5 maximal dominant weights in irreducible representation of highest weight $\Lambda_1 + \Lambda_2 + \Lambda_3$, and we determine their strings.

It was shown in [KacPeterson] that each string is the set of Fourier coefficients of a modular form.

Every weight μ such that the weight multiplicity $m(\mu)$ is nonzero has the form

$$\Lambda - n_0\alpha_0 - n_1\alpha_1 - \cdots,$$

where the n_i are nonnegative integers. This is represented internally as a tuple $(n_0, n_1, n_2, \ldots)$. If you want an individual multiplicity you use the method `m()` and supply it with this tuple:

```
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0]); V
Integrable representation of ['C', 2, 1] with highest weight 2*Lambda[0]
sage: V.m((3,5,3))
18
```

The `IntegrableRepresentation` class has methods `to_weight()` and `from_weight()` to convert between this internal representation and the weight lattice:

```
sage: delta = V.weight_lattice().null_root()
sage: V.to_weight((4,3,2))
-3*Lambda[0] + 6*Lambda[1] - Lambda[2] - 4*delta
sage: V.from_weight(-3*Lambda[0] + 6*Lambda[1] - Lambda[2] - 4*delta)
(4, 3, 2)
```

To get more values, use the depth parameter:

```
sage: L0 = RootSystem(["A",1,1]).weight_lattice(extended=true).fundamental_weight(0); L0
Lambda[0]
sage: IntegrableRepresentation(4*L0).print_strings(depth=20)
4*Lambda[0]: 1 1 3 6 13 23 44 75 131 215 354 561 889 1368 2097 3153 4712 6936 10151 14677
2*Lambda[0] + 2*Lambda[1] - delta: 1 2 5 10 20 36 66 112 190 310 501 788 1230 1880 2850 4256 630
4*Lambda[1] - 2*delta: 1 2 6 11 23 41 75 126 215 347 561 878 1368 2082 3153 4690 6936 10121 1467
```

An example in type $C_2^{(1)}$:

```
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings()     # long time
2*Lambda[0]: 1 2 9 26 77 194 477 1084 2387 5010 10227 20198
Lambda[0] + Lambda[2] - delta: 1 5 18 55 149 372 872 1941 4141 8523 17005 33019
2*Lambda[1] - delta: 1 4 15 44 122 304 721 1612 3469 7176 14414 28124
2*Lambda[2] - 2*delta: 2 7 26 72 194 467 1084 2367 5010 10191 20198 38907
```

Examples for twisted affine types:

```
sage: Lambda = RootSystem(["A",2,2]).weight_lattice(extended=True).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]).strings()
{Lambda[0]: [1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56]}
sage: Lambda = RootSystem(['G',2,1]).dual.weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0]+Lambda[1]+Lambda[2])
```

```
sage: V.print_strings() # long time
6*Lambdacheck[0]: 4 28 100 320 944 2460 6064 14300 31968 69020 144676 293916
4*Lambdacheck[0] + Lambdacheck[2]: 4 22 84 276 800 2124 5288 12470 28116 61056 128304 261972
3*Lambdacheck[0] + Lambdacheck[1]: 2 16 58 192 588 1568 3952 9520 21644 47456 100906 207536
Lambdacheck[0] + Lambdacheck[1] + Lambdacheck[2]: 1 6 26 94 294 832 2184 5388 12634 28390 61488
2*Lambdacheck[1] - deltacheck: 2 8 32 120 354 980 2576 6244 14498 32480 69776 145528

```

branch (*i=None*, *weyl_character_ring=None*, *sequence=None*, *depth=5*)

Return the branching rule on `self`.

Removing any node from the extended Dynkin diagram of the affine Lie algebra results in the Dynkin diagram of a classical Lie algebra, which is therefore a Lie subalgebra. For example removing the 0 node from the Dynkin diagram of type `[X, r, 1]` produces the classical Dynkin diagram of `[X, r]`.

Thus for each i in the index set, we may restrict `self` to the corresponding classical subalgebra. Of course `self` is an infinite dimensional representation, but each weight μ is assigned a grading by the number of times the simple root α_i appears in $\Lambda - \mu$. Thus the branched representation is graded and we get sequence of finite-dimensional representations which this method is able to compute.

OPTIONAL:

- `i` – (default: 0) an element of the index set
- `weyl_character_ring` – a WeylCharacterRing
- `sequence` – a dictionary
- `depth` – (default: 5) an upper bound for k determining how many terms to give

In the default case where $i = 0$, you do not need to specify anything else, though you may want to increase the depth if you need more terms.

EXAMPLES:

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: b = V.branch(); b
[A2(0,0),
 A2(1,1),
 A2(0,0) + 2*A2(1,1) + A2(2,2),
 2*A2(0,0) + 2*A2(0,3) + 4*A2(1,1) + 2*A2(3,0) + 2*A2(2,2),
 4*A2(0,0) + 3*A2(0,3) + 10*A2(1,1) + 3*A2(3,0) + A2(1,4) + 6*A2(2,2) + A2(4,1),
 6*A2(0,0) + 9*A2(0,3) + 20*A2(1,1) + 9*A2(3,0) + 3*A2(1,4) + 12*A2(2,2) + 3*A2(4,1) + A2(3,
```

If the parameter `weyl_character_ring` is omitted, the ring may be recovered as the parent of one of the branched coefficients:

```
sage: A2 = b[0].parent(); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

If i is not zero then you should specify the `WeylCharacterRing` that you are branching to. This is determined by the Dynkin diagram:

```
sage: Lambda = RootSystem(['B',3,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type().dynkin_diagram()
    O 0
    |
    |
O---O=>=O
1   2   3
B3~
```

In this example, we observe that removing the $i = 2$ node from the Dynkin diagram produces a reducible diagram of type `A1xA1xA1`. Thus we have a branching to $\mathfrak{sl}(2) \times \mathfrak{sl}(2) \times \mathfrak{sl}(2)$:

```
sage: A1xA1xA1 = WeylCharacterRing("A1xA1xA1",style="coroots")
sage: V.branch(i=2,weyl_character_ring=A1xA1xA1)
[A1xA1xA1(1,0,0),
 A1xA1xA1(0,1,2),
 A1xA1xA1(1,0,0) + A1xA1xA1(1,2,0) + A1xA1xA1(1,0,2),
 A1xA1xA1(2,1,2) + A1xA1xA1(0,1,0) + 2*A1xA1xA1(0,1,2),
 3*A1xA1xA1(1,0,0) + 2*A1xA1xA1(1,2,0) + A1xA1xA1(1,2,2) + 2*A1xA1xA1(1,0,2) + A1xA1xA1(1,0,
 A1xA1xA1(2,1,0) + 3*A1xA1xA1(2,1,2) + 2*A1xA1xA1(0,1,0) + 5*A1xA1xA1(0,1,2) + A1xA1xA1(0,1,
```

If the nodes of the two Dynkin diagrams are not in the same order, you must specify an additional parameter, `sequence` which gives a dictionary to the affine Dynkin diagram to the classical one.

EXAMPLES:

```
sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type().dynkin_diagram()
O---O---O=>=O---O
0   1   2   3   4
F4~
sage: A1xC3=WeylCharacterRing("A1xC3",style="coroots")
sage: A1xC3.dynkin_diagram()
O
1
O---O=<=O
2   3   4
A1xC3
```

Observe that removing the $i = 1$ node from the `F4~` Dynkin diagram gives the `A1xC3` diagram, but the roots are in a different order. The nodes $0, 2, 3, 4$ of `F4~` correspond to `1, 4, 3, 2` of `A1xC3` and so we encode this in a dictionary:

```
sage: V.branch(i=1,weyl_character_ring=A1xC3,sequence={0:1,2:4,3:3,4:2}) # long time
[A1xC3(1,0,0,0),
 A1xC3(0,0,0,1),
 A1xC3(1,0,0,0) + A1xC3(1,2,0,0),
 A1xC3(2,0,0,1) + A1xC3(0,0,0,1) + A1xC3(0,1,1,0),
 2*A1xC3(1,0,0,0) + A1xC3(1,0,1,0) + 2*A1xC3(1,2,0,0) + A1xC3(1,0,2,0) + A1xC3(3,0,0,0),
 2*A1xC3(2,0,0,1) + A1xC3(2,1,1,0) + A1xC3(0,1,0,0) + 3*A1xC3(0,0,0,1) + 2*A1xC3(0,1,1,0) +
```

The branch method gives a way of computing the graded dimension of the integrable representation:

```
sage: Lambda = RootSystem("A1~").weight_lattice(extended=true).fundamental_weights()
sage: V=IntegrableRepresentation(Lambda[0])
sage: r = [x.degree() for x in V.branch(depth=15)]; r
```

```
[1, 3, 4, 7, 13, 19, 29, 43, 62, 90, 126, 174, 239, 325, 435, 580]
sage: oeis(r)                                                    # optional -- internet
0: A029552: Expansion of phi(x) / f(-x) in powers of x where phi(), f() are Ramanujan theta
```

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type()
['F', 4, 1]
```

coxeter_number()

Return the Coxeter number of the Cartan type of `self`.

The Coxeter number is defined in [Kac] Chapter 6, and commonly denoted h.

EXAMPLES:

```
sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.coxeter_number()
12
```

dominant_maximal_weights()

Return the dominant maximal weights of `self`.

A weight μ is *maximal* if it has nonzero multiplicity but $\mu + \delta$‘ has multiplicity zero. There are a finite number of dominant maximal weights. Indeed, [Kac] Proposition 12.6 shows that the dominant maximal weights are in bijection with the classical weights in $k \cdot F$ where F is the fundamental alcove and k is the level. The construction used in this method is based on that Proposition.

EXAMPLES:

```
sage: Lambda = RootSystem(['C',3,1]).weight_lattice(extended=true).fundamental_weights()
sage: IntegrableRepresentation(2*Lambda[0]).dominant_maximal_weights()
(2*Lambda[0],
 Lambda[0] + Lambda[2] - delta,
 2*Lambda[1] - delta,
 Lambda[1] + Lambda[3] - 2*delta,
 2*Lambda[2] - 2*delta,
 2*Lambda[3] - 3*delta)
```

dual_coxeter_number()

Return the dual Coxeter number of the Cartan type of `self`.

The dual Coxeter number is defined in [Kac] Chapter 6, and commonly denoted $h^\vee$.

EXAMPLES:

```
sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.dual_coxeter_number()
9
```

from_weight(*mu*)

Return the tuple $(n_0, n_1, ...)$‘ such that `mu` equals $\Lambda - \sum_{i \in I} n_i \alpha_i$ in `self`, where Λ is the highest weight of `self`.

EXAMPLES:

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
-2*Lambda[0] + Lambda[1] + 3*Lambda[2] - delta
sage: delta = V.weight_lattice().null_root()
sage: V.from_weight(-2*Lambda[0] + Lambda[1] + 3*Lambda[2] - delta)
(1, 0, 0)
```

highest_weight()

Returns the highest weight of `self`.

EXAMPLES:

```
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+2*Lambda[2]).highest_weight()
Lambda[0] + 2*Lambda[2]
```

level()

Return the level of `self`.

The level of a highest weight representation V_Λ is defined as $(\Lambda|\delta)$ See [Kac] section 12.4.

EXAMPLES:

```
sage: Lambda = RootSystem(['G',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: [IntegrableRepresentation(Lambda[i]).level() for i in [0,1,2]]
[1, 1, 2]
```

m(n)

Return the multiplicity of the weight μ in `self`, where $\mu = \Lambda - \sum_i n_i \alpha_i$.

INPUT:

- `n` – a tuple representing a weight μ.

EXAMPLES:

```
sage: Lambda = RootSystem(['E',6,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: u = V.highest_weight() - V.weight_lattice().null_root()
sage: V.from_weight(u)
(1, 1, 2, 2, 3, 2, 1)
sage: V.m(V.from_weight(u))
6
```

modular_characteristic(*mu=None*)

Return the modular characteristic of `self`.

The modular characteristic is a rational number introduced by Kac and Peterson [KacPeterson], required to interpret the string functions as Fourier coefficients of modular forms. See [Kac] Section 12.7. Let k be the level, and let $h^\vee$ be the dual Coxeter number. Then

$$m_\Lambda = \frac{|\Lambda+\rho|^2}{2(k+h^\vee)} - \frac{|\rho|^2}{2h^\vee}$$

If μ is a weight, then

$$m_{\Lambda,\mu} = m_\Lambda - \frac{|\mu|^2}{2k}.$$

OPTIONAL:

- mu – a weight; or alternatively:
- n – a tuple representing a weight μ.

If no optional parameter is specified, this returns m_Λ. If mu is specified, it returns $m_{\Lambda,\mu}$. You may use the tuple n to specify μ. If you do this, μ is $\Lambda - \sum_i n_i \alpha_i$.

EXAMPLES:

```
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0]+2*Lambda[1])
sage: [V.modular_characteristic(x) for x in V.dominant_maximal_weights()]
[11/56, -1/280, 111/280]
```

print_strings(*depth=12*)

Print the strings of self.

See also:

strings()

EXAMPLES:

```
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings(depth=25)
2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741 3740 5096 68
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687 2331 3206 4368
```

root_lattice()

Return the root lattice associated to self.

EXAMPLES:

```
sage: V=IntegrableRepresentation(RootSystem(['F',4,1]).weight_lattice(extended=true).fundame
sage: V.root_lattice()
Root lattice of the Root system of type ['F', 4, 1]
```

s(*n*, *i*)

Return the action of the i-th simple reflection on the internal representation of weights by tuples n in self.

EXAMPLES:

```
sage: V = IntegrableRepresentation(RootSystem(['A',2,1]).weight_lattice(extended=true).funda
sage: [V.s((0,0,0),i) for i in V._index_set]
[(1, 0, 0), (0, 0, 0), (0, 0, 0)]
```

string(*max_weight*, *depth=12*)

Return the list of multiplicities $m(\Lambda - k\delta)$ in self, where Λ is max_weight and k runs from 0 to depth.

INPUT:

- max_weight – a dominant maximal weight
- depth – (default: 12) the maximum value of k

EXAMPLES:

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.string(2*Lambda[0])
[1, 2, 8, 20, 52, 116, 256, 522, 1045, 1996, 3736, 6780]
```

```
sage: V.string(Lambda[1] + Lambda[2])
[0, 1, 4, 12, 32, 77, 172, 365, 740, 1445, 2736, 5041]
```

strings(*depth=12*)

Return the set of dominant maximal weights of `self`, together with the string coefficients for each.

OPTIONAL:

- `depth` – (default: 12) a parameter indicating how far to push computations

EXAMPLES:

```
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: S = V.strings(depth=25)
sage: for k in S:
....:     print "{}: {}".format(k, ' '.join(str(x) for x in S[k]))
2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741 3740 5096 68
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687 2331 3206 4368
```

to_dominant(*n*)

Return the dominant weight in `self` equivalent to `n` under the affine Weyl group.

EXAMPLES:

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0])
sage: n = V.to_dominant((13,11,7)); n
(4, 3, 3)
sage: V.to_weight(n)
Lambda[0] + Lambda[1] + Lambda[2] - 4*delta
```

to_weight(*n*)

Return the weight associated to the tuple `n` in `self`.

If `n` is the tuple $(n_1, n_2, \ldots)$, then the associated weight is $\Lambda - \sum_i n_i \alpha_i$, where Λ is the weight of the representation.

INPUT:

- `n` – a tuple representing a weight

EXAMPLES:

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
-2*Lambda[0] + Lambda[1] + 3*Lambda[2] - delta
```

weight_lattice()

Return the weight lattice associated to `self`.

EXAMPLES:

```
sage: V=IntegrableRepresentation(RootSystem(['E',6,1]).weight_lattice(extended=true).fundame
sage: V.weight_lattice()
Extended weight lattice of the Root system of type ['E', 6, 1]
```

5.1.204 Nonsymmetric Macdonald polynomials

AUTHORS:

- Anne Schilling and Nicolas M. Thiery (2013): initial version

ACKNOWLEDGEMENTS:

The initial version of this code (together with root_lattice_realization_algebras.Algebras and hecke_algebra_representation.HeckeAlgebraRepresentation) was written by Anne Schilling and Nicolas M. Thiery during the ICERM Semester Program on "Automorphic Forms, Combinatorial Representation Theory and Multiple Dirichlet Series" (January 28, 2013 - May 3, 2013) with the help of Dan Bump, Ben Brubaker, Bogdan Ion, Dan Orr, Arun Ram, Siddhartha Sahi, and Mark Shimozono. Special thanks go to Bogdan Ion and Mark Shimozono for their patient explanations and hand computations to check the code.

class sage.combinat.root_system.non_symmetric_macdonald_polynomials.**NonSymmetricMacdonaldPoly**

Bases: sage.combinat.root_system.hecke_algebra_representation.CherednikOperatorsEigenvect

Nonsymmetric Macdonald polynomials

INPUT:

- KL – an affine Cartan type or the group algebra of a realization of the affine weight lattice
- q, q1, q2 – parameters in the base ring of the group algebra (default: q, q1, q2)
- normalized – a boolean (default: True) whether to normalize the result to have leading coefficient 1

This implementation covers all reduced affine root systems. The polynomials are constructed recursively by the application of intertwining operators.

Todo

- Non-reduced case (Koornwinder polynomials).
- Non-equal parameters for the affine Hecke algebra.
- Choice of convention (dominant/anti-dominant, ...).
- More uniform implementation of the $T_0^\vee$ operator.
- Optimizations, in particular in the calculation of the eigenvalues for the recursion.

EXAMPLES:

We construct the family of nonsymmetric Macdonald polynomials in three variables in type A:

```
sage: E = NonSymmetricMacdonaldPolynomials(["A",2,1])
```

They are constructed as elements of the group algebra of the classical weight lattice L_0 (or one of its realizations, such as the ambient space, which is used here) and indexed by elements of L_0:

```
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['A', 2]
```

Here is the nonsymmetric Macdonald polynomial with leading term $[2,0,1]$:

```
sage: E[L0([2,0,1])]
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 1, 1)] + ((-q1-q2)/(-q*q1-q2))*B[(2, 1, 0)] + B[(2, 0, 1)]
```

It can be seen as a polynomial (or in general a Laurent polynomial) by interpreting each term as an exponent vector. The parameter q is the exponential of the null (co)root, whereas q_1 and q_2 are the two eigenvalues of each generator T_i of the affine Hecke algebra (see the background section for details).

By setting $q_1 = t, q_2 = -1$ and using the root_lattice_realization_algebras.Algebras.ElementMethods.e method, we recover the nonsymmetric Macdonald polynomial as computed by [HHL06]'s combinatorial formula:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(["A",2,1], q=q, q1=t, q2=-1)
sage: vars = K['x0,x1,x2'].gens()
sage: E[L0([2,0,1])].expand(vars)
((-t + 1)/(-q*t + 1))*x0^2*x1 + x0^2*x2 + ((-q*t + q)/(-q*t + 1))*x0*x1*x2

sage: from sage.combinat.sf.ns_macdonald import E
sage: E([2,0,1])
((-t + 1)/(-q*t + 1))*x0^2*x1 + x0^2*x2 + ((-q*t + q)/(-q*t + 1))*x0*x1*x2
```

Here is a type $G_2^{(1)}$ nonsymmetric Macdonald polynomial:

```
sage: E = NonSymmetricMacdonaldPolynomials(["G",2,1])
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[ omega[2]-omega[1] ]
((-q*q1^3*q2-q*q1^2*q2^2)/(q*q1^4-q2^4))*B[(0, 0, 0)] + B[(1, -1, 0)] + ((-q1*q2^3-q2^4)/(q*q1^4
```

Many more examples are given after the background section.

- sage.combinat.sf.ns_macdonald.E()
- SymmetricFunctions.macdonald()

Background

The polynomial module

The nonsymmetric Macdonald polynomials are a distinguished basis of the "polynomial" module of the affine Hecke algebra. Given:

```
- a ground ring `K`, which contains the input parameters `q, q_1, q_2`
- an affine root system, specified by a Cartan type `C`
- a realization `L` of the weight lattice of type `C`
```

the polynomial module is the group algebra $K[L_0]$ of the classical weight lattice L_0 with coefficients in K. It is isomorphic to the Laurent polynomial ring over K generated by the formal exponentials of any basis of L_0.

In our running example L is the ambient space of type $C_2^{(1)}$:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: C = CartanType(["C",2,1])
sage: L = RootSystem(C).ambient_space(); L
Ambient space of the Root system of type ['C', 2, 1]

sage: L.simple_roots()
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
```

```
sage: omega = L.fundamental_weights(); omega
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'], 2: e[0] + e[1] + e['deltacheck']}

sage: L0 = L.classical(); L0
Ambient space of the Root system of type ['C', 2]
sage: KL0 = L0.algebra(K); KL0
Group algebra of the Ambient space of the Root system of type ['C', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

Affine Hecke algebra

The affine Hecke algebra is generated by elements T_i for `i` in the set of affine Dynkin nodes. They satisfy the same braid relations as the simple reflections s_i of the affine Weyl group. The T_i satisfy the quadratic relation

$$(T_i - q_1) \circ (T_i - q_2) = 0$$

where q_1 and q_2 are the input parameters. Some of the representation theory requires that q_1 and q_2 satisfy additional relations; typically one uses the specializations $q_1 = u$ and $q_2 = -1/u$ or $q_1 = t$ and $q_2 = -1$). This can be achieved by constructing an appropriate field and passing q_1 and q_2 appropriately; see the examples. In principle, the parameter(s) could further depend on `i`; this is not yet implemented but the code has been designed in such a way that this feature is easy to add.

Demazure-Lusztig operators

The `i`-th Demazure-Lusztig operator is an operator on $K[L]$ which interpolates between the reflection s_i and the Demazure operator π_i (see `root_lattice_realization.RootLatticeRealization.Algebras.ParentMethods.demazure_lusztig`

```
sage: KL = L.algebra(K); KL
Group algebra of the Ambient space of the Root system of type ['C', 2, 1]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: x = KL.monomial(omega[1]); x
B[e[0] + e['deltacheck']]
sage: T[2](x)
q1*B[e[0] + e['deltacheck']]
sage: T[1](x)
(q1+q2)*B[e[0] + e['deltacheck']] + q1*B[e[1] + e['deltacheck']]
sage: T[0](x)
q1*B[e[0] + e['deltacheck']]
```

The affine Hecke algebra acts on $K[L]$ by letting the generators T_i act by the Demazure-Lusztig operators. The class `sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation` implements some simple generic features for representations of affine Hecke algebras defined by the action of their T-generators.:

```
sage: T
A representation of the (q1, q2)-Hecke algebra of type ['C', 2, 1] on Group algebra of the Ambie
sage: type(T)
<class 'sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation'>
sage: T._test_relations()                    # long time (1.3s)
```

Here we construct the operator $q_1 T_2^{-1} \circ T_1^{-1} T_0$ from a signed reduced word:

```
sage: T.Tw([0,1,2],[1,-1,-1], q1^2)
Generic endomorphism of Group algebra of the Ambient space of the Root system of type ['C', 2, 1
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

(note the reversal of the word). Inverses are computed using the quadratic relation.

Cherednik operators

The affine Hecke algebra contains elements Y_λ indexed by the coroot lattice. Their action on $K[L]$ is implemented in Sage:

```
sage: Y = T.Y(); Y
Lazy family (...)_{i in Coroot lattice of the Root system of type ['C', 2, 1]}
sage: alphacheck = Y.keys().simple_roots()
sage: Y1 = Y[alphacheck[1]]
sage: Y1(x)
((q1^3+q1^2*q2)/(-q2^3))*B[-e[0] - 2*e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[-e[0] - e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[e[0] - 2*e[1] - 2*e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[e[0] - 2*e[1] - e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[e[0] - 2*e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[e[0] - e['delta'] + e['deltacheck']] + ((q1^2+2*q1*q2+q2^2)/(-q1*q2
+ ((q1^3+q1^2*q2)/(-q2^3))*B[2*e[0] - e[1] - 2*e['delta'] + e['deltacheck']]
+ ((-q1^2-q1*q2)/(-q2^2))*B[2*e[0] - e[1] - e['delta'] + e['deltacheck']] + (q1^3/(-q2^3))*B[3*e
+ ((q1^3+q1^2*q2)/(-q2^3))*B[3*e[0] - 3*e['delta'] + e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(-q2^3))*B[-e[1] - e['delta'] + e['deltacheck']]

```

The Cherednik operators span a Laurent polynomial ring inside the affine Hecke algebra; namely $\lambda \mapsto Y_\lambda$ is a group isomorphism from the classical root lattice (viewed additively) to the affine Hecke algebra (viewed multiplicatively). In practice, Y_λ is constructed by computing combinatorially its signed reduced word (and an overall scalar factor) using the periodic orientation of the alcove model in the coweight lattice (see `hecke_algebra_representation.HeckeAlgebraRepresentation.Y_lambdacheck()`):

```
sage: Lcheck = L.root_system.coweight_lattice()
sage: w = Lcheck.reduced_word_of_translation(Lcheck(alphacheck[1])); w
[0, 2, 1, 0, 2, 1]
sage: Lcheck.signs_of_alcovewalk(w)
[1, -1, 1, -1, 1, 1]
```

Level zero representation of the affine Hecke algebra

The action of the affine Hecke algebra on $K[L]$ induces an action on $K[L_0]$: the action of T_i on X^λ for λ a classical weight in L_0 is obtained by embedding the weight at level zero in the affine weight lattice (see `weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.embed_at_level()`) applying the Demazure-Lusztig operator there, and projecting from $K[L] \to K[L_0]$ mapping the exponential of δ to q (see `root_lattice_realization_algebras.Algebras.ParentMethods.q_project()`). This is implemented in `root_lattice_realization_algebras.Algebras.ParentMethods.demazure_lusztig`

```
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1,q2)
sage: omega = L0.fundamental_weights()
sage: x = KL0.monomial(omega[1])
sage: T[0](x)
(-q*q2)*B[(-1, 0)]
```

For classical nodes these are the usual Demazure-Lusztig operators:

```
sage: T[1](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]
```

Nonsymmetric Macdonald polynomials

We can now finally define the nonsymmetric Macdonald polynomials. Because the Cherednik operators commute (and there is no radical), they can be simultaneously diagonalized; namely, $K[L_0]$ admits a K-basis of joint eigenvectors for the Y_λ. For $\mu \in L_0$, the nonsymmetric Macdonald polynomial E_μ is the unique eigenvector of the family of Cherednik operators Y_λ having μ as leading term:

```
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2); E
The family of the Macdonald polynomials of type ['C', 2, 1] with parameters q, q1, q2
```

Or for short:

```
sage: E = NonSymmetricMacdonaldPolynomials(C)
```

Recursive construction of the nonsymmetric Macdonald polynomials

The generators T_i of the affine Hecke algebra almost skew commute with the Cherednik operators. More precisely, one can deform them into the so-called intertwining operators:

$$\tau_i = T_i - (q_1 + q_2)\frac{Y_i^{a-1}}{1 - Y_i^a}\,.$$

(where $a = 1$ except for $i = 0$ in type BC where $a = a_0 = 2$) which satisfy the following skew commutation relations:

$$\tau_i Y_\lambda = \tau_i Y_{s_i\lambda}\,.$$

If $s_i\mu \neq \mu$, applying τ_i on an eigenvector E_μ produces a new eigenvector (essentially $E_{s_i\mu}$) with a distinct eigenvalue. It follows that the eigenvectors indexed by an affine Weyl orbit of weights, may be recursively computed from a single weight in the orbit.

In the case at hand, there is a little complication: namely, the simple reflections s_i acting at level 0 do not act transitively on classical weights; in fact the orbits for the classical Weyl group and for the affine Weyl group are the same. Thus, one can construct the nonsymmetric Macdonald polynomials for all weights from those for the classical dominant weights, but one is lacking a creation operator to construct the nonsymmetric Macdonald polynomials for dominant weights.

Twisted Demazure-Lusztig operators

To compensate for this, one needs to consider another affinization of the action of the classical Demazure-Lusztig operators $T_1, \ldots, T_n$, which gives rise to the double affine Hecke algebra. Following Cherednik, one adds another operator $T_0^\vee$ implemented in: root_lattice_realization_algebras.Algebras.ParentMethods.T0_check_on_basis().
See also: root_lattice_realization_algebras.Algebras.ParentMethods.twisted_demazure_luszti

Depending on the type (untwisted or not), this is a representation of the affine Hecke algebra for another affinization of the classical Cartan type. The corresponding action of the affine Weyl group – which is used to compute the recursion on μ – occurs in the corresponding weight lattice realization:

```
sage: E.L()
Ambient space of the Root system of type ['C', 2, 1]
sage: E.L_prime()
Coambient space of the Root system of type ['B', 2, 1]
sage: E.L_prime().classical()
Ambient space of the Root system of type ['C', 2]
```

See `L_prime()` and `cartan_type.CartanType_affine.other_affinization()`.

More examples

We show how to create the nonsymmetric Macdonald polynomials in two different ways and check that they are the same:

```
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['D',3,1], q, u, -1/u)
sage: omega = E.keys().fundamental_weights()
sage: E[omega[1]+omega[3]]
((-q*u^2+q)/(-q*u^4+1))*B[(1/2, -1/2, 1/2)] + ((-q*u^2+q)/(-q*u^4+1))*B[(1/2, 1/2, -1/2)] + B[(3

sage: KL = RootSystem(["D",3,1]).ambient_space().algebra(K)
sage: P = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
sage: E[omega[1]+omega[3]] == P[omega[1]+omega[3]]
True
sage: E[E.keys()((0,1,-1))]
((-q*u^2+q)/(-q*u^2+1))*B[(0, 0, 0)] + ((-u^2+1)/(-q*u^2+1))*B[(1, 1, 0)]
+ ((-u^2+1)/(-q*u^2+1))*B[(1, 0, -1)] + B[(0, 1, -1)]
```

In type A, there is also a combinatorial implementation of the nonsymmetric Macdonald polynomials in terms of augmented diagram fillings as in [HHL06]. See `sage.combinat.sf.ns_macdonald.E()`. First we check that these polynomials are indeed eigenvectors of the Cherednik operators:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t; q2 = -1
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: KL0 = KL.classical()
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: omega = E.keys().fundamental_weights()
sage: w = omega[1]
sage: import sage.combinat.sf.ns_macdonald as NS
sage: p = NS.E([1,0,0]); p
x0
sage: pp = KL0.from_polynomial(p)
sage: E.eigenvalues(KL0.from_polynomial(p))
[t, (-1)/(-q*t^2), t]

sage: def eig(l): return E.eigenvalues(KL0.from_polynomial(NS.E(l)))

sage: eig([1,0,0])
[t, (-1)/(-q*t^2), t]
sage: eig([2,0,0])
[q*t, (-1)/(-q^2*t^2), t]
sage: eig([3,0,0])
[q^2*t, (-1)/(-q^3*t^2), t]
```

```
sage: eig([2,0,4])
[(-1)/(-q^3*t), 1/(q^2*t), q^4*t^2]
```

Next we check explicitly that they agree with the current implementation:

```
sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(["A",1,1]).ambient_lattice().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: L0 = E.keys()
sage: KL0 = KL.classical()
sage: P = K['x0,x1']
sage: def EE(weight): return E[L0(weight)].expand(P.gens())
sage: import sage.combinat.sf.ns_macdonald as NS
sage: EE([0,0])
1
sage: NS.E([0,0])
1
sage: EE([1,0])
x0
sage: NS.E([1,0])
x0
sage: EE([0,1])
((-t + 1)/(-q*t + 1))*x0 + x1
sage: NS.E([0,1])
((-t + 1)/(-q*t + 1))*x0 + x1

sage: NS.E([2,0])
x0^2 + ((-q*t + q)/(-q*t + 1))*x0*x1
sage: EE([2,0])
x0^2 + ((-q*t + q)/(-q*t + 1))*x0*x1
```

The same, directly in the ambient lattice with several shifts:

```
sage: E[L0([2,0])]
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]
sage: E[L0([1,-1])]
((-q*t+q)/(-q*t+1))*B[(0, 0)] + B[(1, -1)]
sage: E[L0([0,-2])]
((-q*t+q)/(-q*t+1))*B[(-1, -1)] + B[(0, -2)]
```

Systematic checks with Sage's implementation of [HHL06]:

```
sage: assert all(EE([x,y]) == NS.E([x,y]) for d in range(5) for x,y in IntegerVectors(d,2))
```

With the current implementation, we can compute nonsymmetric Macdonald polynomials for any type, for example for type $E_6^{(1)}$:

```
sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(["E",6,1]).weight_space(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q,u,-1/u)
sage: L0 = E.keys()

sage: E[L0.fundamental_weight(1).weyl_action([2,4,3,2,1])]
((-u^2+1)/(-q*u^16+1))*B[-Lambda[1] + Lambda[3]] + ((-u^2+1)/(-q*u^16+1))*B[Lambda[1]]
+ B[-Lambda[2] + Lambda[5]] + ((-u^2+1)/(-q*u^16+1))*B[Lambda[2] - Lambda[4] + Lambda[5]]
+ ((-u^2+1)/(-q*u^16+1))*B[-Lambda[3] + Lambda[4]]
```

```
sage: E[L0.fundamental_weight(2).weyl_action([2,5,3,4,2])]  # long time (6s)
((-q^2*u^20+q^2*u^18+q*u^2-q)/(-q^2*u^32+2*q*u^16-1))*B[0]
+ B[Lambda[1] - Lambda[3] + Lambda[4] - Lambda[5] + Lambda[6]]
+ ((-u^2+1)/(-q*u^16+1))*B[Lambda[1] - Lambda[3] + Lambda[5]]
+ ((-q*u^20+q*u^18+u^2-1)/(-q^2*u^32+2*q*u^16-1))*B[-Lambda[2] + Lambda[4]]
+ ((-q*u^20+q*u^18+u^2-1)/(-q^2*u^32+2*q*u^16-1))*B[Lambda[2]]
+ ((u^4-2*u^2+1)/(q^2*u^32-2*q*u^16+1))*B[Lambda[3] - Lambda[4] + Lambda[5]]
+ ((-u^2+1)/(-q*u^16+1))*B[Lambda[3] - Lambda[5] + Lambda[6]]

sage: E[L0.fundamental_weight(1)+L0.fundamental_weight(6)]  # long time (13s)
((q^2*u^10-q^2*u^8-q^2*u^2+q^2)/(q^2*u^26-q*u^16-q*u^10+1))*B[0]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] - Lambda[2] + Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] + Lambda[2] - Lambda[4] + Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] - Lambda[3] + Lambda[4] - Lambda[5] + Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[1] - Lambda[3] + Lambda[5]] + B[Lambda[1] + Lambda[6]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[-Lambda[2] + Lambda[4]] + ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[2]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[3] - Lambda[4] + Lambda[5]]
+ ((-q*u^2+q)/(-q*u^10+1))*B[Lambda[3] - Lambda[5] + Lambda[6]]
```

We test various other types:

```
sage: K=QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = RootSystem(["A",5,2]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
sage: L0 = E.keys()
sage: E[L0.fundamental_weight(2)]

Some tests that the T s are implemented properly by hand defining the Y s in terms of them:

```
sage: T = E._T_Y
sage: Ye1     = T.Tw((1,2,1,0), scalar = (-1/(q1*q2))^2)
sage: Ye2     = T.Tw((2,1,0,1), signs = (1,1,1,-1), scalar = (-1/(q1*q2)))
sage: Yalpha0 = T.Tw((0,1,2,1), signs = (-1,-1,-1,-1), scalar = q^-1*(-q1*q2)^2)
sage: Yalpha1 = T.Tw((1,2,0,1,2,0), signs=(1,1,-1,1,-1,1), scalar = -1/(q1*q2))
sage: Yalpha2 = T.Tw((2,1,0,1,2,1,0,1), signs = (1,1,1,-1,1,1,1,-1), scalar = (1/(q1*q2))^2)

sage: Ye1(KL0.one())
q1^2/q2^2*B[(0, 0)]
sage: Ye2(KL0.one())
((-q1)/q2)*B[(0, 0)]

sage: Yalpha0(KL0.one())
q2^2/(q*q1^2)*B[(0, 0)]
sage: Yalpha1(KL0.one())
((-q1)/q2)*B[(0, 0)]
sage: Yalpha2(KL0.one())
q1^2/q2^2*B[(0, 0)]
```

Testing the Y s directly:

```
sage: Y = E.Y()
sage: Y.keys()
Coroot lattice of the Root system of type ['BC', 2, 2]
sage: alpha = Y.keys().simple_roots()
sage: L(alpha[0])
-2*e[0] + e['deltacheck']
sage: L(alpha[1])
e[0] - e[1]
```

```
sage: L(alpha[2])
e[1]

sage: Y[alpha[0]].word
(0, 1, 2, 1)
sage: Y[alpha[0]].signs
(-1, -1, -1, -1)
sage: Y[alpha[0]].scalar # mind that Sage's q is the usual q^{1/2}
q1^2*q2^2/q
sage: Y[alpha[0]](KL0.one())
q2^2/(q*q1^2)*B[(0, 0)]

sage: Y[alpha[1]].word
(1, 2, 0, 1, 2, 0)
sage: Y[alpha[1]].signs
(1, 1, -1, 1, -1, 1)
sage: Y[alpha[1]].scalar
1/(-q1*q2)

sage: Y[alpha[2]].word    # Bogdan says it should be the square of that; do we need to take tran
(2, 1, 0, 1)
sage: Y[alpha[2]].signs
(1, 1, 1, -1)
sage: Y[alpha[2]].scalar
1/(-q1*q2)
```

Checking the provided nonsymmetric Macdonald polynomial:

```
sage: E10 = KL0.monomial(L0((1,0))) + KL0( q*(1-(-q1/q2)) / (1-q^2*(-q1/q2)^4) )
sage: E10 == E[omega[1]]
True
sage: E.eigenvalues(E10)  # not checked
[q*q1^2/q2^2, q2^3/(-q^2*q1^3), q1/(-q2)]
```

Checking T0check:

```
sage: T0check_on_basis = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: T0check_on_basis.phi # note: this is in fact a0 phi
(2, 0)
sage: T0check_on_basis.v   # what to match it with?
(1,)
sage: T0check_on_basis.j   # what to match it with?
2
sage: T0check_on_basis(KL0.basis().keys().zero())
((-q1^2)/q2)*B[(1, 0)]

sage: T0check = E._T[0]
sage: T0check(KL0.one())
((-q1^2)/q2)*B[(1, 0)]
```

Systematic tests of nonsymmetric Macdonald polynomials in type $A_1^{(1)}$, in the weight lattice. Each time, we specify the eigenvalues for the action of Y_{α_0}, and Y_{α_1}:

```
sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(["A",1,1]).weight_lattice(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: omega = E.keys().fundamental_weights()
```

```
sage: x = E[0*omega[1]]; x
B[0]
sage: E.eigenvalues(x)
[1/(q*t), t]
sage: x.is_one()
True
sage: x.parent()
Group algebra of the Weight lattice of the Root system of type ['A', 1]

[(-1)/(-q^2*t), q*t]
```

As expected, $e^{-\omega}$ is not an eigenvector:

```
sage: E.eigenvalues(KL.classical().monomial(-omega[1]))
Traceback (most recent call last):
...
AssertionError
```

We proceed by comparing against the examples from the appendix of [HHL06] in type $A_2^{(1)}$:

```
sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: P = K['x1,x2,x3']
sage: def EE(weight): return E[L0(weight)].expand(P.gens())

sage: EE([0,0,0])
1
sage: EE([1,0,0])
x1
sage: EE([0,1,0])
((-t + 1)/(-q*t^2 + 1))*x1 + x2
```

```
sage: EE([0,0,1])
((-t + 1)/(-q*t + 1))*x1 + ((-t + 1)/(-q*t + 1))*x2 + x3
sage: EE([1,1,0])
x1*x2
sage: EE([1,0,1])
((-t + 1)/(-q*t^2 + 1))*x1*x2 + x1*x3
sage: EE([0,1,1])
((-t + 1)/(-q*t + 1))*x1*x2 + ((-t + 1)/(-q*t + 1))*x1*x3 + x2*x3
sage: EE([2,0,0])
x1^2 + ((-q*t + q)/(-q*t + 1))*x1*x2 + ((-q*t + q)/(-q*t + 1))*x1*x3

sage: EE([0,2,0])
((-t + 1)/(-q^2*t^2 + 1))*x1^2 + ((-q^2*t^3 + q^2*t^2 - q*t^2 + 2*q*t - q + t - 1)/(-q^3*t^3 + q
```

Systematic checks with Sage's implementation of [HHL06]:

```
sage: import sage.combinat.sf.ns_macdonald as NS
sage: assert all(EE([x,y,z]) == NS.E([x,y,z]) for d in range(5) for x,y,z in IntegerVectors(d,3)
```

We check that we get eigenvectors for generic q_1, q_2:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2 = K.gens()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
sage: E[2*omega[2]]
((q*q1+q*q2)/(q*q1+q2))*B[(1, 2, 1)] + ((q*q1+q*q2)/(q*q1+q2))*B[(2, 1, 1)] + B[(2, 2, 0)]
sage: for d in range(4):                                    # long time (9s)
...       for weight in IntegerVectors(d,3).map(list).map(L0):
...           eigenvalues = E.eigenvalues(E[L0(weight)])
```

Some type C calculations:

```

((-q^2*t^4+q^2*t^3-q*t^3+2*q*t^2-q*t+t-1)/(-q^3*t^4+q^2*t^3+q*t-1))*B[(0, 0)] + B[(-1, -1)] + ((
sage: E.eigenvalues(_)  # not checked                    # long time (1s)
[1/(q^3*t^3), t, q*t]
sage: E[-omega[2]].map_coefficients(lambda c: c.subs(t=0))     # checking againsts crystals
B[(0, 0)] + B[(-1, -1)] + B[(-1, 1)] + B[(1, -1)] + B[(1, 1)]

sage: E[2*omega[2]]
((-q^6*t^7+q^6*t^6-q^5*t^6+2*q^5*t^5-q^4*t^5-q^5*t^3+3*q^4*t^4-3*q^4*t^3+q^3*t^4+q^4*t^2-2*q^3*t
sage: E.eigenvalues(_)  # not checked
[q^3*t^3, t, (-1)/(-q^2*t^2)]
```

The following computations were calculated by hand:

```
sage: KL0 = KL.classical()
sage: E11 = KL0.sum_of_terms([[L0([1,1]), 1], [L0([0,0]), (-q*t^2 + q*t)/(1-q*t^3)]])
sage: E11 == E[omega[2]]
True
sage: E.eigenvalues(E11)
[q*t^3, t, (-1)/(-q*t^2)]

sage: E1m1 = KL0.sum_of_terms([[L0([1,-1]), 1], [L0([1,1]), (1-t)/(1-q*t^2)], [L0([0,0]), q*t*(1
sage: E1m1 == E[2*omega[1]-omega[2]]
True
sage: E.eigenvalues(E1m1)
[1/(q*t), 1/(q^2*t^3), q*t^2]
```

Now we present an example for a twisted affine root system. The results are eigenvectors:

```
sage: K = QQ['q','t'].fraction_field()
sage: q, t = K.gens()
sage: KL = RootSystem("C2~*").ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: omega = E.keys().fundamental_weights()
sage: E[0*omega[1]]
B[(0, 0)]
sage: E.eigenvalues(_)
[1/(q*t^2), t, t]
sage: E[omega[1]]
((-q*t+q)/(-q*t^2+1))*B[(0, 0)] + B[(1, 0)]
sage: E.eigenvalues(_)
[q*t^2, 1/(q^2*t^3), t]

sage: E[-omega[1]]
((-q*t+q-t+1)/(-q^2*t+1))*B[(0, 0)] + B[(-1, 0)] + ((-t+1)/(-q^2*t+1))*B[(1, 0)] + ((-t+1)/(-q^2
sage: E.eigenvalues(_)
[(-1)/(-q^3*t^2), q^2*t, t]
sage: E[-omega[1]+omega[2]]
B[(-1/2, 1/2)] + ((-t+1)/(-q^2*t^3+1))*B[(1/2, -1/2)] + ((-q*t^3+q*t^2-t+1)/(-q^2*t^3+1))*B[(1/2
sage: E.eigenvalues(_)
[(-1)/(-q^2*t^2), q^2*t^3, (-1)/(-q*t)]
sage: E[omega[1]-omega[2]]
B[(1/2, -1/2)] + ((-t+1)/(-q*t^2+1))*B[(1/2, 1/2)]
sage: E.eigenvalues(_)
[t, 1/(q^2*t^3), q*t^2]
```

Type BC, comparison with calculations with Maple by Bogdan Ion:

```
sage: K = QQ['q','t'].fraction_field()
sage: q,t = K.gens()
sage: def to_SR(x): return x.expand([SR.var('x%s'%i) for i in range(1,x.parent().basis().keys().
sage: var('x1,x2,x3')
(x1, x2, x3)

sage: E = NonSymmetricMacdonaldPolynomials(["BC",2,2], q=q, q1=t^2,q2=-1)
sage: omega=E.keys().fundamental_weights()
sage: expected = (t-1)*(t+1)*(2+q^4+2*q^2-2*t^2-2*q^2*t^2-t^4*q^2-q^4*t^4+t^4-3*q^6*t^6-2*q^4*t^
sage: to_SR(E[2*omega[2]]) - expected                    # long time (3.5s)
0

sage: E = NonSymmetricMacdonaldPolynomials(["BC",3,2], q=q, q1=t^2,q2=-1)
sage: omega=E.keys().fundamental_weights()
sage: mu = -3*omega[1] + 3*omega[2] - omega[3]; mu
(-1, 2, -1)
sage: expected = (t-1)^2*(t+1)^2*(3*q^2+q^4+1+t^2*q^4+q^2*t^2-3*t^4*q^2-5*t^6*q^4+2*t^8*q^4-4*t^
sage: to_SR(E[mu]) - expected                            # long time (20s)
0

sage: E = NonSymmetricMacdonaldPolynomials(["BC",1,2], q=q, q1=t^2,q2=-1)
sage: omega=E.keys().fundamental_weights()
sage: mu = -4*omega[1]; mu
(-4)
sage: expected = (t-1)*(t+1)*(-1+q^2*t^2-q^2-3*q^10-7*q^26*t^8+5*t^2*q^6-q^16-3*q^4+4*t^10*q^30-
sage: to_SR(E[mu]) - expected
0
```

Type BC dual, comparison with hand calculations by Bogdan Ion:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2 = K.gens()
sage: ct = CartanType(["BC",2,2]).dual()
sage: E = NonSymmetricMacdonaldPolynomials(ct, q=q, q1=q1, q2=q2)
sage: KL = E.domain(); KL
Group algebra of the Ambient space of the Root system of type ['B', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
sage: alpha = E.keys().simple_roots(); alpha
Finite family {1: (1, -1), 2: (0, 1)}
sage: omega=E.keys().fundamental_weights(); omega
Finite family {1: (1, 0), 2: (1/2, 1/2)}
sage: epsilon = E.keys().basis(); epsilon
Finite family {0: (1, 0), 1: (0, 1)}
```

Note: Sage's q is the usual q^2:

```
sage: E.L().null_root()
e['delta']
sage: E.L().null_coroot()
2*e['deltacheck']
```

Some eigenvectors:

```
sage: E[0*omega[1]]
B[(0, 0)]
sage: E[omega[1]]
((-q^2*q1^3*q2-q^2*q1^2*q2^2)/(q^2*q1^4-q2^4))*B[(0, 0)] + B[(1, 0)]
```

```
sage: Eomega1 = KL.one() * (q^2*(-q1/q2)^2*(1-(-q1/q2))) / (1-q^2*(-q1/q2)^4) + KL.monomial(omeg
sage: E[omega[1]] == Eomega1
True
```

Checking the Y s:

```
sage: Y = E.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: Y0 = Y[alphacheck[0]]
sage: Y1 = Y[alphacheck[1]]
sage: Y2 = Y[alphacheck[2]]

sage: Y0.word, Y0.signs, Y0.scalar
((0, 1, 2, 1, 0, 1, 2, 1), (-1, -1, -1, -1, -1, -1, -1, -1), q1^4*q2^4/q^2)
sage: Y1.word, Y1.signs, Y1.scalar
((1, 2, 0, 1, 2, 0), (1, 1, -1, 1, -1, 1), 1/(-q1*q2))
sage: Y2.word, Y2.signs, Y2.scalar
((2, 1, 0, 1), (1, 1, 1, -1), 1/(-q1*q2))

sage: E.eigenvalues(0*omega[1])
[q2^4/(q^2*q1^4), q1/(-q2), q1/(-q2)]
```

Checking the T and T^{-1} s:

```
sage: T = E._T_Y
sage: Tinv0 = T.Tw_inverse([0])
sage: Tinv1 = T.Tw_inverse([1])
sage: Tinv2 = T.Tw_inverse([2])

sage: for x in [0*epsilon[0], -epsilon[0], -epsilon[1], epsilon[0], epsilon[1]]:
....:     x = KL.monomial(x)
....:     assert Tinv0(T[0](x)) == x and T[0](Tinv0(x)) == x
....:     assert Tinv1(T[1](x)) == x and T[1](Tinv1(x)) == x
....:     assert Tinv2(T[2](x)) == x and T[2](Tinv2(x)) == x

sage: start = E[omega[1]]; start
((-q^2*q1^3*q2-q^2*q1^2*q2^2)/(q^2*q1^4-q2^4))*B[(0, 0)] + B[(1, 0)]
sage: Tinv1(Tinv2(Tinv1(Tinv0(Tinv1(Tinv2(Tinv1(Tinv0(start))))))) * (q1*q2)^4/q^2 == Y0(start)
True
sage: Y0(start) == q^2*q1^4/q2^4 * start
True
```

Checking the relation between the Y s:

```
sage: q^2 * Y0(Y1(Y1(Y2(Y2(start))))) == start
True
sage: for x in [0*epsilon[0], -epsilon[0], -epsilon[1], epsilon[0], epsilon[1]]:
....:     x = KL.monomial(x)
....:     assert q^2 * Y0(Y1(Y1(Y2(Y2(start))))) == start
```

KL0()

Return the group algebra where the nonsymmetric Macdonald polynomials live.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").KL0()
Group algebra of the Ambient space of the Root system of type ['B', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
sage: NonSymmetricMacdonaldPolynomials("B2~*").KL0()
Group algebra of the Ambient space of the Root system of type ['C', 2]
```

```
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

L()

Return the affinization of the classical weight space.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L()
Ambient space of the Root system of type ['B', 2, 1]
```

L0()

Return the space indexing the monomials of the nonsymmetric Macdonald polynomials.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").L0()
Ambient space of the Root system of type ['B', 2]
sage: NonSymmetricMacdonaldPolynomials("B2~*").L0()
Ambient space of the Root system of type ['C', 2]
```

L_check()

Return the other affinization of the classical weight space.

Todo

should this just return L in the simply laced case?

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L_check()
Coambient space of the Root system of type ['C', 2, 1]
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L_check().classical()
Ambient space of the Root system of type ['B', 2]
```

L_prime()

The affine space where classical weights are lifted for the recursion.

Also the parent of ρ'.

EXAMPLES:

In the twisted case, this is the affinization of the classical ambient space:

```
sage: NonSymmetricMacdonaldPolynomials("B2~*").L()
Ambient space of the Root system of type ['B', 2, 1]^*
sage: NonSymmetricMacdonaldPolynomials("B2~*").L().classical()
Ambient space of the Root system of type ['C', 2]

sage: NonSymmetricMacdonaldPolynomials("B2~*").L_prime()
Ambient space of the Root system of type ['B', 2, 1]^*
sage: NonSymmetricMacdonaldPolynomials("B2~*").L_prime().classical()
Ambient space of the Root system of type ['C', 2]
```

In the untwisted case, this is the other affinization of the classical ambient space:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").L()
Ambient space of the Root system of type ['B', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("B2~").L().classical()
Ambient space of the Root system of type ['B', 2]

sage: NonSymmetricMacdonaldPolynomials("B2~").L_prime()
```

```
Coambient space of the Root system of type ['C', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("B2~").L_prime().classical()
Ambient space of the Root system of type ['B', 2]
```

For simply laced, the two affinizations coincide:

```
sage: NonSymmetricMacdonaldPolynomials("A2~").L()
Ambient space of the Root system of type ['A', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("A2~").L().classical()
Ambient space of the Root system of type ['A', 2]

sage: NonSymmetricMacdonaldPolynomials("A2~").L_prime()
Coambient space of the Root system of type ['A', 2, 1]
sage: NonSymmetricMacdonaldPolynomials("A2~").L_prime().classical()
Ambient space of the Root system of type ['A', 2]
```

Note: do we want the coambient space of type $A_2^{(1)}$ instead?

For type BC:

```
sage: NonSymmetricMacdonaldPolynomials(["BC",3,2]).L_prime()
Ambient space of the Root system of type ['BC', 3, 2]
```

Q_to_Qcheck()

The reindexing of the index set of the Y's by the coroot lattice.

EXAMPLES:

```
sage: E = NonSymmetricMacdonaldPolynomials("C2~")
sage: alphacheck = E.Y().keys().simple_roots()
sage: E.Q_to_Qcheck(alphacheck[0])
alphacheck[0] - alphacheck[2]
sage: E.Q_to_Qcheck(alphacheck[1])
alphacheck[1]
sage: E.Q_to_Qcheck(alphacheck[2])
alphacheck[2]

sage: x = alphacheck[1] + 2*alphacheck[2]
sage: x.parent()
Root lattice of the Root system of type ['B', 2, 1]
sage: E.Q_to_Qcheck(x)
alphacheck[1] + 2*alphacheck[2]
sage: _.parent()
Coroot lattice of the Root system of type ['C', 2, 1]
```

Y()

Return the family of Y operators whose eigenvectors are the nonsymmetric Macdonald polynomials.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials("C2~").Y()
Lazy family (<lambda>(i))_{i in Root lattice of the Root system of type ['B', 2, 1]}
sage: _.keys().classical()
Root lattice of the Root system of type ['B', 2]

sage: NonSymmetricMacdonaldPolynomials("C2~*").Y()
Lazy family (<...Y_lambdacheck...>(i))_{i in Coroot lattice of the Root system of type ['C',
sage: _.keys().classical()
Root lattice of the Root system of type ['C', 2]
```

```
sage: NonSymmetricMacdonaldPolynomials(["BC", 3, 2]).Y()
Lazy family (<...Y_lambdacheck...>(i))_{i in Coroot lattice of the Root system of type ['BC'
sage: _.keys().classical()
Root lattice of the Root system of type ['B', 3]
```

affine_lift(*mu*)

Return the affinization of μ in L'.

INPUT:

- mu – a classical weight μ

See also:

- hecke_algebra_representation.CherednikOperatorsEigenvectors.affine_lift()
- affine_retract()
- L_prime()

EXAMPLES:

In the untwisted case, this is the other affinization at level 1:

```
sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Coambient space of the Root system of type ['C', 2, 1]
```

In the twisted case, this is the usual affinization at level 1:

```
sage: E = NonSymmetricMacdonaldPolynomials("B2~*")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['C', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Ambient space of the Root system of type ['B', 2, 1]^*
```

affine_retract(*mu*)

Retract the affine weight μ into a classical weight.

INPUT:

- mu – an affine weight μ in L'

See also:

- hecke_algebra_representation.HeckeAlgebraRepresentation.affine_retract()
- affine_lift()
- L_prime()

EXAMPLES:

```
sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_retract(E.affine_lift(omega[1]))
(1, 0)
```

cartan_type()

Return Cartan type of `self`.

EXAMPLES:

```
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).cartan_type()
['B', 2, 1]
```

eigenvalue_experimental(*mu*, *l*)

Return the eigenvalue of $Y^{\lambda^\vee}$ acting on the macdonald polynomial E_μ.

INPUT:

- `mu` – the index μ of an eigenvector
- l – an index $\lambda^\vee$ of some Y

Note:

- This method is currently not used; most tests below even test the naive method. They are left here as a basis for a future implementation.
- This is actually equivariant, as long as s_i does not fix λ.
- This method is only really needed for $\lambda^\vee = \alpha_i^\vee$ with $i = 0, ..., n$.

See Corollary 6.11 of [Haiman06].

EXAMPLES:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = RootSystem(["A",1,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: E.eigenvalues(L0([0,0])) # Checked by hand by Mark and Arun
[1/(q*t), t]
sage: alpha = E.Y().keys().simple_roots()
sage: E.eigenvalue_experimental(L0([0,0]), alpha[0]) # todo: not implemented
1/(q*t)
sage: E.eigenvalue_experimental(L0([0,0]), alpha[1])
t
```

Some examples of eigenvalues (not mathematically checked!!!):

```
sage: E.eigenvalues(L0([1,0]))
[t, 1/(q*t)]
sage: E.eigenvalues(L0([0,1]))
[1/(q^2*t), q*t]
sage: E.eigenvalues(L0([1,1]))
```

```
[1/(q*t), t]
sage: E.eigenvalues(L0([2,1]))
[t, 1/(q*t)]
sage: E.eigenvalues(L0([-1,1]))
[(-1)/(-q^3*t), q^2*t]
sage: E.eigenvalues(L0([-2,1]))
[(-1)/(-q^4*t), q^3*t]
sage: E.eigenvalues(L0([-2,0]))
[(-1)/(-q^3*t), q^2*t]
```

Some type B examples:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
sage: q2 = -1
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()
sage: E.eigenvalue(L0((0,0)), alpha[0]) # not checked # not tested
q/t
sage: E.eigenvalue(L0((1,0)), alpha[1]) # What Mark got by hand # not tested
q
sage: E.eigenvalue(L0((1,0)), alpha[2]) # not checked # not tested
t
sage: E.eigenvalue(L0((1,0)), alpha[0]) # not checked # not tested
1

sage: L = RootSystem("B2~*").ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()
sage: E.eigenvalue(L0((0,0)), alpha[0]) # assuming Mark's calculation is correct, one should
1/(q*t^2)
```

The expected value can more or less be read off from equation (37), Corollary 6.15 of [Haiman06]

Todo

- Use proposition 6.9 of [Haiman06] to check the action of the Y s on monomials.
- Generalize to any q_1, q_2.
- Check claim by Mark: all scalar products should occur in the finite weight lattice, with alpha 0 being the appropriate projection of the affine alpha 0. Question: can this be emulated by being at level 0?

---

rho_prime()

Return the level 0 sum of the classical fundamental weights in L'.

See also:

L_prime()

EXAMPLES:

Untwisted case:

```
sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime() # CHECKME
3/2*e[0] + 1/2*e[1]
sage: NonSymmetricMacdonaldPolynomials("B2~").rho_prime().parent()
Coambient space of the Root system of type ['C', 2, 1]
```

Twisted case:

```
sage: NonSymmetricMacdonaldPolynomials("B2~*").rho_prime() # CHECKME
2*e[0] + e[1]
sage: NonSymmetricMacdonaldPolynomials("B2~*").rho_prime().parent()
Ambient space of the Root system of type ['B', 2, 1]^*
```

seed(*mu*)

Return E_μ for μ minuscule, i.e. in the fundamental alcove.

INPUT:

- mu – the index μ of an eigenvector

EXAMPLES:

```
sage: E = NonSymmetricMacdonaldPolynomials(["A",2,1])
sage: omega = E.keys().fundamental_weights()
sage: E.seed(omega[1])
B[(1, 0, 0)]
```

symmetric_macdonald_polynomial(*mu*)

Return the symmetric Macdonald polynomial indexed by μ.

INPUT:

- mu – a dominant weight μ

Warning: The result is Weyl-symmetric only for Hecke parameters of the form $q_1 = v$ and $q_2 = -1/v$. In general the value of v below, should be the square root of $-q_1/q_2$, but the use of $q_1 = t$ and $q_2 = -1$ results in nonintegral powers of t.

EXAMPLES:

```
sage: K = QQ['q,v,t'].fraction_field()
sage: q,v,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['A',2,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[2])
B[(1, 1, 0)] + B[(1, 0, 1)] + B[(0, 1, 1)]
sage: E.symmetric_macdonald_polynomial(2*om[1])
((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 1, 0)] + ((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 0, 1)] + B[(2,
sage: f = E.symmetric_macdonald_polynomial(E.L0()((2,1,0))); f
((2*q*v^4+v^4-q*v^2+v^2-q-2)/(q*v^4-1))*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1
```

We compare with the type A Macdonald polynomials coming from symmetric functions:

```
sage: P = SymmetricFunctions(K).macdonald().P()
sage: g = P[2,1].expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + ((-2*q*t^2 + q*t - t^2 + q - t + 2)/(-q*t^2 + 1))*x0*x1*x2 + x
sage: fe =f.expand(g.parent().gens()); fe
x0^2*x1 + x0*x1^2 + x0^2*x2 + ((2*q*v^4 + v^4 - q*v^2 + v^2 - q - 2)/(q*v^4 - 1))*x0*x1*x2 +
sage: g.map_coefficients(lambda x: x.subs(t=v*v)) == fe
True
```

```
sage: E = NonSymmetricMacdonaldPolynomials(['C',3,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[1]+om[2])
B[(-2, -1, 0)] + B[(-2, 1, 0)] + B[(-2, 0, -1)] + B[(-2, 0, 1)] + ((4*q^3*v^14+2*q^2*v^14-2*
```

An example for type G:

```
sage: E = NonSymmetricMacdonaldPolynomials(['G',2,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(2*om[1])
((3*q^6*v^22+3*q^5*v^22-3*q^6*v^20+q^4*v^22-4*q^5*v^20+q^4*v^18-q^5*v^16+q^3*v^18-2*q^4*v^16
```

twist (*mu*, *i*)

Act by s_i on the affine weight μ.

This calls `simple_reflection`; which is semantically the same as the default implementation.

EXAMPLES:

```
sage: W = WeylGroup(["B",3])
sage: W.element_class._repr_=lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231
```

5.1.205 Pieri Factors

class sage.combinat.root_system.pieri_factors.**PieriFactors**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

An abstract class for sets of Pieri factors, used for constructing Stanley symmetric functions. The set of Pieri factors for a given type can be realized as an order ideal of the Bruhat order poset generated by a certain set of maximal elements.

See also:

- `WeylGroups.ParentMethods.pieri_factors()`
- `WeylGroups.ElementMethods.stanley_symmetric_function()`

EXAMPLES:

```
sage: W = WeylGroup(['A',4])
sage: PF = W.pieri_factors()
sage: PF.an_element().reduced_word()
[4, 3, 2, 1]
sage: Waff = WeylGroup(['A',4,1])
sage: PFaff = Waff.pieri_factors()
sage: Waff.from_reduced_word(PF.an_element().reduced_word()) in PFaff
True
```

```
sage: W = WeylGroup(['B',3,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,2]) in PF.elements()
True
sage: PF.cardinality()
47

sage: W = WeylGroup(['C',3,1])
sage: PF = W.pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
sage: [w.reduced_word() for w in PF if w.length() == 2]
[[2, 0], [0, 1], [2, 3], [1, 2], [3, 2], [3, 1], [2, 1], [3, 0], [1, 0]]
```

REFERENCES:

default_weight()

Returns the function $i \mapsto z^i$, where z is the generator of `QQ['z']`.

EXAMPLES:

```
sage: W = WeylGroup(["A", 3, 1])
sage: weight = W.pieri_factors().default_weight()
sage: weight(1)
z
sage: weight(5)
z^5
```

TESTS:

```
sage: weight(4) in QQ['z']
True
sage: weight(0) in QQ['z']
True
sage: weight(0).parent() == QQ['z']  # todo: not implemented
True
```

elements()

Returns the elements of `self`

Those are constructed as the elements below the maximal elements of `self` in Bruhat order.

OUTPUT: a `RecursivelyEnumeratedSet_generic` object

EXAMPLES:

```
sage: PF = WeylGroup(['A',3]).pieri_factors()
sage: [w.reduced_word() for w in PF.elements()]
[[3, 2, 1], [2, 1], [1], [], [3, 1], [3], [3, 2], [2]]
```

See also:

`maximal_elements()`

Todo

Possibly remove this method and instead have this class inherit from `RecursivelyEnumeratedSet_generic`.

---

generating_series(*weight=None*)

Returns a length generating series for the elements of `self`

EXAMPLES:

```
sage: PF = WeylGroup(['C',3,1]).pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1

sage: PF = WeylGroup(['B',4]).pieri_factors()
sage: PF.generating_series()
z^7 + 6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
```

max_length()

Return the maximal length of a Pieri factor.

EXAMPLES:

In type A and A affine, this is n:

```
sage: WeylGroup(['A',5]).pieri_factors().max_length()
5
sage: WeylGroup(['A',5,1]).pieri_factors().max_length()
5
```

In type B and B affine, this is $2n-1$:

```
sage: WeylGroup(['B',5,1]).pieri_factors().max_length()
9
sage: WeylGroup(['B',5]).pieri_factors().max_length()
9
```

In type C affine this is $2n$:

```
sage: WeylGroup(['C',5,1]).pieri_factors().max_length()
10
```

In type D affine this is $2n-2$:

```
sage: WeylGroup(['D',5,1]).pieri_factors().max_length()
8
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_affine_type**

Bases: sage.combinat.root_system.pieri_factors.PieriFactors

maximal_elements()

Return the maximal elements of `self` with respect to Bruhat order.

The current implementation is via a conjectural type-free formula. Use maximal_elements_combinatorial() for proven type-specific implementations. To compare type-free and type-specific (combinatorial) implementations, use method `_test_maximal_elements()`.

EXAMPLES:

```
sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 4, 3, 2], [1, 0, 4, 3], [2, 1, 0, 4], [3, 2, 1, 0], [4, 3, 2, 1]]

sage: W = WeylGroup(RootSystem(["C",3,1]).weight_space())
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
```

```
 [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]

sage: W = WeylGroup(RootSystem(["B",3,1]).weight_space())
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 2, 3, 2, 0], [1, 0, 2, 3, 2], [1, 2, 3, 2, 1],
 [2, 1, 0, 2, 3], [2, 3, 2, 1, 0], [3, 2, 1, 0, 2]]

sage: W = WeylGroup(['D',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 2, 4, 3, 2, 0], [1, 0, 2, 4, 3, 2], [1, 2, 4, 3, 2, 1],
 [2, 1, 0, 2, 4, 3], [2, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3],
 [4, 2, 1, 0, 2, 4], [4, 3, 2, 1, 0, 2]]
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_finite_type**

Bases: sage.combinat.root_system.pieri_factors.PieriFactors

The Pieri factors of finite type A are the restriction of the Pieri factors of affine type A to finite permutations (under the canonical embedding of finite type A into the affine Weyl group), and the Pieri factors of finite type B are the restriction of the Pieri factors of affine type C. The finite type D Pieri factors are (weakly) conjectured to be the restriction of the Pieri factors of affine type D.

maximal_elements()

The current algorithm uses the fact that the maximal Pieri factors of affine type A,B,C, or D either contain a finite Weyl group element, or contain an affine Weyl group element whose reflection by s_0 gets a finite Weyl group element, and that either of these finite group elements will serve as a maximal element for finite Pieri factors. A better algorithm is desirable.

EXAMPLES:

```
sage: PF = WeylGroup(['A',5]).pieri_factors()
sage: [v.reduced_word() for v in PF.maximal_elements()]
[[5, 4, 3, 2, 1]]

sage: WeylGroup(['B',4]).pieri_factors().maximal_elements()
[
[-1  0  0  0]
[ 0  1  0  0]
[ 0  0  1  0]
[ 0  0  0  1]
]
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_type_A**(*W*)

Bases: sage.combinat.root_system.pieri_factors.PieriFactors_finite_type

The set of Pieri factors for finite type A.

This is the set of elements of the Weyl group that have a reduced word that is strictly decreasing. May also be viewed as the restriction of affine type A Pieri factors to finite Weyl group elements.

maximal_elements_combinatorial()

Returns the maximal Pieri factors, using the type A combinatorial description

EXAMPLES:

```
sage: W = WeylGroup(['A',4])
sage: PF = W.pieri_factors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
[4, 3, 2, 1]
```

stanley_symm_poly_weight(*w*)

EXAMPLES:

```
sage: W = WeylGroup(['A',4])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,1]))
0
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_type_A_affine**(*W*, *min_length*, *max_length*, *min_support*, *max_support*)

Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The set of Pieri factors for type A affine, that is the set of elements of the Weyl Group which are cyclically decreasing.

Those are used for constructing (affine) Stanley symmetric functions.

The Pieri factors are in bijection with the proper subsets of the index_set. The bijection is given by the support. Namely, let f be a Pieri factor, and red a reduced word for f. No simple reflection appears twice in red, and the support S of red (that is the i such that s_i appears in red) does not depend on the reduced word).

cardinality()

EXAMPLES:

```
sage: WeylGroup(["A", 3, 1]).pieri_factors().cardinality()
15
```

generating_series(*weight=None*)

Returns a length generating series for the elements of `self`

EXAMPLES:

```
sage: W = WeylGroup(["A", 3, 1])
sage: W.pieri_factors().cardinality()
15
sage: W.pieri_factors().generating_series()
4*z^3 + 6*z^2 + 4*z + 1
```

maximal_elements_combinatorial()

Returns the maximal Pieri factors, using the affine type A combinatorial description

EXAMPLES:

```
sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[3, 2, 1, 0], [2, 1, 0, 4], [1, 0, 4, 3], [0, 4, 3, 2], [4, 3, 2, 1]]
```

stanley_symm_poly_weight(*w*)

Weight used in computing (affine) Stanley symmetric polynomials for affine type A.

EXAMPLES:

```
sage: W = WeylGroup(['A',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.one())
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,4,2,1,0]))
0
```

subset(*length*)

INPUT:

- `length` – a non-negative integer

Returns the subset of the elements of `self` of length `length`

sage: PF = WeylGroup(["A", 3, 1]).pieri_factors(); PF Pieri factors for Weyl Group of type ['A', 3, 1] (as a matrix group acting on the root space) sage: PF3 = PF.subset(length = 2) sage: PF3.cardinality() 6

TESTS:

We check that there is no reference effect (there was at some point!):

```
sage: PF.cardinality()
15
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_type_B**(*W*)
Bases: sage.combinat.root_system.pieri_factors.PieriFactors_finite_type

The type B finite Pieri factors are realized as the set of elements that have a reduced word that is a subword of 12...(n-1)n(n-1)...21. They are the restriction of the type C affine Pieri factors to the set of finite Weyl group elements under the usual embedding.

maximal_elements_combinatorial()
Returns the maximal Pieri factors, using the type B combinatorial description

EXAMPLES:

```
sage: PF = WeylGroup(['B',4]).pieri_factors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
[1, 2, 3, 4, 3, 2, 1]
```

stanley_symm_poly_weight(*w*)
Weight used in computing Stanley symmetric polynomials of type B. The weight for finite type B is the number of components of the support of an element minus the number of occurrences of n in a reduced word.

EXAMPLES:

```
sage: W = WeylGroup(['B',5])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,1,5]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,4,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,2,3,4,5,4]))
0
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_type_B_affine**(*W*)
Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The type B affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

•cyclic rotations of the element with reduced word 234...(n-1)n(n-1)...3210, except for 123...n...320 and 023...n...321.

•123...(n-1)n(n-1)...321

•023...(n-1)n(n-1)...320

EXAMPLES:

```
sage: W = WeylGroup(['B',4,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,4,3,2,1,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,1]) in PF.maximal_elements()
False
sage: W.from_reduced_word([1,0,2,3,4,3,2]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,0]) in PF
True
```

maximal_elements_combinatorial()

Returns the maximal Pieri factors, using the affine type B combinatorial description

EXAMPLES:

```
sage: W = WeylGroup(['B',4,1])
sage: [u.reduced_word() for u in W.pieri_factors().maximal_elements_combinatorial()]
[[1, 0, 2, 3, 4, 3, 2], [2, 1, 0, 2, 3, 4, 3], [3, 2, 1, 0, 2, 3, 4], [4, 3, 2, 1, 0, 2, 3],
```

stanley_symm_poly_weight(*w*)

Returns the weight of a Pieri factor to be used in the definition of Stanley symmetric functions. For type B, this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. We also consider 0 and 1 to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type C). Let n be the rank of the affine Weyl group in question (if type ['B',k,1] then we have n = k+1). Let chi(v.length() < n-1) be the indicator function that is 1 if the length of v is smaller than n-1, and 0 if the length of v is greater than or equal to n-1. If we say c'(v) = the number of components of the complement of the support of v, then the type B weight is given by weight = c'(v) - chi(v.length() < n-1).

EXAMPLES:

```
sage: W = WeylGroup(['B',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,1,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,3,4,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,4,5,4,3,0]))
-1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([4,5,4,3,0]))
0
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_type_C_affine**(*W*)

Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The type C affine Pieri factors are realized as the order ideal (in Bruhat order) generated by cyclic rotations of the element with unique reduced word 123...(n-1)n(n-1)...3210.

EXAMPLES:

```
sage: W = WeylGroup(['C',3,1])
sage: PF = W.pieri_factors()
sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
 [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]
```

maximal_elements_combinatorial()

Returns the maximal Pieri factors, using the affine type C combinatorial description

EXAMPLES:

```
sage: PF = WeylGroup(['C',3,1]).pieri_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [2, 1, 0, 1, 2, 3], [3, 2, 1, 0, 1, 2], [2, 3, 2, 1
```

stanley_symm_poly_weight(*w*)

Returns the weight of a Pieri factor to be used in the definition of Stanley symmetric functions. For type C, this weight is the number of connected components of the support (the indices appearing in a reduced word) of an element.

EXAMPLES:

```
sage: W = WeylGroup(['C',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,3]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,3,2,0]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,3,0]))
3
sage: PF.stanley_symm_poly_weight(W.one())
0
```

class sage.combinat.root_system.pieri_factors.**PieriFactors_type_D_affine**(*W*)

Bases: sage.combinat.root_system.pieri_factors.PieriFactors_affine_type

The type D affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

- cyclic rotations of the element with reduced word 234...(n-2)n(n-1)(n-2)...3210 such that 1 and 0 are always adjacent and (n-1) and n are always adjacent.
- 123...(n-2)n(n-1)(n-2)...321
- 023...(n-2)n(n-1)(n-2)...320
- n(n-2)...2102...(n-2)n
- (n-1)(n-2)...2102...(n-2)(n-1)

EXAMPLES:

```
sage: W = WeylGroup(['D',5,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([3,2,1,0]) in PF
True
sage: W.from_reduced_word([0,3,2,1]) in PF
False
sage: W.from_reduced_word([0,1,3,2]) in PF
True
sage: W.from_reduced_word([2,0,1,3]) in PF
```

```
True
sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
[[0, 2, 3, 5, 4, 3, 2, 0], [1, 0, 2, 3, 5, 4, 3, 2], [1, 2, 3, 5, 4, 3, 2, 1],
 [2, 1, 0, 2, 3, 5, 4, 3], [2, 3, 5, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3, 5, 4],
 [3, 5, 4, 3, 2, 1, 0, 2], [4, 3, 2, 1, 0, 2, 3, 4], [5, 3, 2, 1, 0, 2, 3, 5],
 [5, 4, 3, 2, 1, 0, 2, 3]]
```

maximal_elements_combinatorial()

Returns the maximal Pieri factors, using the affine type D combinatorial description

EXAMPLES:

```
sage: W = WeylGroup(['D',5,1])
sage: PF = W.pieri_factors()
sage: set(PF.maximal_elements_combinatorial()) == set(PF.maximal_elements())
True
```

stanley_symm_poly_weight(w)

INPUT:

- w – a pieri factor for this type

Returns the weight of w, to be used in the definition of Stanley symmetric functions. For type D, this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. Similarly with $n-1$ and n. We also consider 0 and 1, n-1 and n to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type C).

Type D Stanley symmetric polynomial weights are still conjectural. The given weight comes from conditions on elements of the affine Fomin-Stanley subalgebra, but work is needed to show this weight is correct for affine Stanley symmetric functions – see [LSS2009, Pon2010] for details.

EXAMPLES:

```
sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,2,1]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,2,1,0]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,2]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([]))
0

sage: W = WeylGroup(['D',7,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,4,6]))
2
```

5.1.206 Tutorial: visualizing root systems

Root systems encode the positions of collections of hyperplanes in space, and form the fundamental combinatorial data underlying Coxeter and Weyl groups, Lie algebras and groups, etc. The theory can be a bit intimidating at first because of the many technical gadgets (roots, coroots, weights, ...). Vizualizing them goes a long way toward building a geometric intuition.

This tutorial starts from simple plots and guides you all the way to advanced plots with your own combinatorial data drawn on top of it.

See also:

- *Root systems* – An overview of root systems in Sage
- `RootLatticeRealizations.ParentMethods.plot()` – the main plotting function, with pointers to all the subroutines

First plots

In this first plot, we draw the root system for type A_2 in the ambient space. It is generated from two hyperplanes at a 120 degree angle:

```
sage: L = RootSystem(["A",2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

Each of those hyperplane $H_{\alpha_i^\vee}$ is described by a linear form $\alpha_i^\vee$ called simple coroot. To each such hyperplane corresponds a reflection along a vector called root. In this picture, the reflections are orthogonal and the two simple roots α_1 and α_2 are vectors which are normal to the reflection hyperplanes. The same color code is used uniformly: blue for 1, red for 2, green for 3, ... (see `CartanType.color()`). The fundamental weights, Λ_1 and Λ_2 form the dual basis of the coroots.

The two reflections generate a group of order six which is nothing but the usual symmetric group S_3, in its natural action by permutations of the coordinates of the ambient space. Wait, but the ambient space should be of dimension 3 then? That's perfectly right. Here is the full picture in 3D:

```
sage: L = RootSystem(["A",2]).ambient_space()
sage: L.plot(projection=False)
Graphics3d Object
```

However in this space, the line $(1,1,1)$ is fixed by the action of the group. Therefore, the so called barycentric projection orthogonal to $(1,1,1)$ gives a convenient 2D picture which contains all the essential information. The same projection is used by default in type G_2:

```
sage: L = RootSystem(["G",2]).ambient_space()
sage: L.plot(reflection_hyperplanes="all")
Graphics object consisting of 21 graphics primitives
```

The group is now the dihedral group of order 12, generated by the two reflections s_1 and s_2. The picture displays the hyperplanes for all 12 reflections of the group. Those reflections delimit 12 chambers which are in one to one correspondance with the elements of the group. The fundamental chamber, which is grayed out, is associated with the identity of the group.

Warning: The fundamental chamber is currently plotted as the cone generated by the fundamental weights. As can be seen on the previous 3D picture this is not quite correct if the fundamental weights do not span the space. Another caveat is that some plotting features may require manipulating elements with rational coordinates which will fail if one is working in, say, the weight lattice. It is therefore recommended to use the root, weight, or ambient spaces for plotting purposes rather than their lattice counterparts.

Coming back to the symmetric group, here is the picture in the weight space, with all roots and all reflection hyperplanes; remark that, unlike in the ambient space, a root is not necessarily orthogonal to its corresponding reflection hyperplane:

```
sage: L = RootSystem(["A",2]).weight_space()
sage: L.plot(roots = "all", reflection_hyperplanes="all").show(figsize=15)
```

Note: Setting a larger figure size as above can help reduce the overlap between the text labels when the figure gets crowded.

One can further customize which roots to display, as in the following example showing the positive roots in the weight space for type ['G',2], labelled by their coordinates in the root lattice:

```
sage: Q = RootSystem(["G",2]).root_space()
sage: L = RootSystem(["G",2]).ambient_space()
sage: L.plot(roots=list(Q.positive_roots()), fundamental_weights=False)
Graphics object consisting of 17 graphics primitives
```

One can also customize the projection by specifying a function. Here, we display all the roots for type E_8 using the projection from its eight dimensional ambient space onto 3D described on Wikipedia's E8 3D picture:

```
sage: M = matrix([[0., -0.556793440452, 0.19694925177, -0.19694925177, 0.0805477263944, -0.385290876
...               [0.180913155536, 0., 0.160212955043, 0.160212955043, 0., 0.0990170516545, 0.766360
...               [0.338261212718, 0, 0, -0.338261212718, 0.672816364803, 0.171502564281, 0, -0.1715
sage: L = RootSystem(["E",8]).ambient_space()
sage: L.dimension()
8
sage: L.plot(roots="all", reflection_hyperplanes=False, projection=lambda v: M*vector(v), labels=Fals
Graphics3d Object
```

The projection function should be linear or affine, and return a vector with rational coordinates. The rationale for the later constraint is to allow for using the PPL exact library for manipulating polytopes. Indeed exact calculations give cleaner pictures (adjacent objects, intersection with the bounding box, ...). Besides the interface to PPL is indeed currently faster than that for CDD, and it is likely to become even more so.

Exercise

Draw all finite root systems in 2D, using the canonical projection onto their Coxeter plane. See Stembridge's page.

Alcoves and chambers

We now draw the root system for type G_2, with its alcoves (in finite type, those really are the chambers) and the corresponding elements of the Weyl group. We enlarge a bit the bounding box to make sure everything fits in the picture:

```
sage: RootSystem(["G",2]).ambient_space().plot(alcoves=True, alcove_labels=True, bounding_box=5)
Graphics object consisting of 37 graphics primitives
```

The same picture in 3D, for type B_3:

```
sage: RootSystem(["B",3]).ambient_space().plot(alcoves=True, alcove_labels=True)
Graphics3d Object
```

Exercise

Can you spot the fundamental chamber? The fundamental weights? The simple roots? The longest element of the Weyl group?

Alcove pictures for affine types

We now draw the usual alcove picture for affine type $A_2^{(1)}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot()                                  # long time
Graphics object consisting of 160 graphics primitives
```

This picture is convenient because it is low dimensional and contains most of the relevant information. Beside, by choosing the ambient space, the elements of the Weyl group act as orthogonal affine maps. In particular, reflections are usual (affine) orthogonal reflections. However this is in fact only a slice of the real picture: the Weyl group actually acts by linear maps on the full ambient space. Those maps stabilize the so-called level l hyperplanes, and we are visualizing here what's happening at level 1. Here is the full picture in 3D:

```
sage: L.plot(bounding_box=[[-3,3],[-3,3],[-1,1]], affine=False) # long time
Graphics3d Object
```

In fact, in type A, this really is a picture in 4D, but as usual the barycentric projection kills the boring extra dimension for us.

It's usually more readable to only draw the intersection of the reflection hyperplanes with the level 1 hyperplane:

```
sage: L.plot(affine=False, level=1)             # long time
Graphics3d Object
```

Such 3D pictures are useful to better understand technicalities, like the fact that the fundamental weights do not necessarily all live at level 1:

```
sage: L = RootSystem(["G",2,1]).ambient_space()
sage: L.plot(affine=False, level=1)
Graphics3d Object
```

Note: Such pictures may tend to be a bit flat, and it may be helpful to play with the aspect_ratio and more generaly with the various options of the `show()` method:

```
sage: p = L.plot(affine=False, level=1)
sage: p.show(aspect_ratio=[1,1,2], frame=False)
```

Exercise

Draw the alcove picture at level 1, and compare the position of the fundamental weights and the vertices of the fundamental alcove.

As for finite root systems, the alcoves are indexed by the elements of the Weyl group W. Two alcoves indexed by u and v respectively share a wall if u and v are neighbors in the right Cayley graph: $u = vs_i$; the color of that wall is given by i:

```
sage: L = RootSystem(["C",2,1]).ambient_space()
sage: L.plot(coroots="simple", alcove_labels=True) # long time
Graphics object consisting of 216 graphics primitives
```

Even 2D pictures of the rank $1 + 1$ cases can give some food for thought. Here, we draw the root lattice, with the positive roots of small height in the root poset:

```
sage: L = RootSystem(["A",1,1]).root_lattice()
sage: seed = L.simple_roots()
sage: succ = attrcall("pred")
sage: positive_roots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_roots)
sage: first_positive_roots = [next(it) for i in range(10)]
sage: L.plot(roots=first_positive_roots, affine=False, alcoves=False)
Graphics object consisting of 24 graphics primitives
```

Exercises

1. Use the same trick to draw the reflection hyperplanes in the weight lattice for the coroots of small height. Add the indexing of the alcoves by elements of the Weyl group. See below for a solution.
2. Draw the positive roots in the weight lattice and in the extended weight lattice.
3. Draw the reflection hyperplanes in the root lattice
4. Recreate John Stembridge's "Sandwich" arrangement pictures by choosing appropriate coroots for the reflection hyperplanes.

Here is a polished solution for the first exercise:

```
sage: L = RootSystem(["A",1,1]).weight_space()
sage: seed = L.simple_coroots()
sage: succ = attrcall("pred")
sage: positive_coroots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_coroots)
sage: first_positive_coroots = [next(it) for i in range(20)]
sage: p = L.plot(fundamental_chamber=True, reflection_hyperplanes=first_positive_coroots,
...              affine=False, alcove_labels=1,
...              bounding_box=[[-9,9],[-1,2]],
...              projection=lambda x: matrix([[1,-1],[1,1]])*vector(x))
sage: p.show(figsize=20)                          # long time
```

Higher dimension affine pictures

We now do some plots for rank 4 affine types, at level 1. The space is tiled by the alcoves, each of which is a 3D simplex:

```
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: L.plot(reflection_hyperplanes=False, bounding_box=85/100) # long time
Graphics3d Object
```

It is recommended to use a small bounding box here, for otherwise the number of simplices grows quicker than what Sage can handle smoothly. It can help to specify explicitly which alcoves to visualize. Here is the fundamental alcove, specified by an element of the Weyl group:

```
sage: W = L.weyl_group()
sage: L.plot(reflection_hyperplanes=False, alcoves=[W.one()], bounding_box=2)
Graphics3d Object
```

and the fundamental polygon, specified by the coordinates of its center in the root lattice:

```
sage: W = L.weyl_group()
sage: L.plot(reflection_hyperplanes=False, alcoves=[[0,0]], bounding_box=2)
Graphics3d Object
```

Finally, we draw the alcoves in the classical fundamental chambers, using that those are indexed by the elements of the Weyl group having no other left descent than 0. In order to see the inner structure, we only draw the wireframe of the facets of the alcoves. Specifying the `wireframe` option requires a more flexible syntax for plots which will be explained later on in this tutorial:

```
sage: L = RootSystem(["B",3,1]).ambient_space()
sage: W = L.weyl_group()
sage: alcoves = [~w for d in range(12) for w in W.affine_grassmannian_elements_of_given_length(d)]
sage: p = L.plot_fundamental_chamber("classical")
sage: p += L.plot_alcoves(alcoves=alcoves, wireframe=True)
sage: p += L.plot_fundamental_weights()
sage: p.show(frame=False)
```

Exercises

1. Draw the fundamental alcove in the ambient space, just by itself (no reflection hyperplane, root, ...). The automorphism group of the Dynkin diagram for $A_3^{(1)}$ (a cycle of length 4) is the dihedral group. Visualize the corresponding symmetries of the fundamental alcove.
2. Draw the fundamental alcoves for the other rank 4 affine types, and recover the automorphism groups of their Dynkin diagram from the pictures.

Drawing on top of a root system plot

The root system plots have been designed to be used as wallpaper on top of which to draw more information. In the following example, we draw an alcove walk, specified by a word of indices of simple reflections, on top of the weight lattice in affine type $A_{2,1}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,1,2,0,2,0,1,2,0]
sage: L.plot(alcove_walk=w1, bounding_box=6)        # long time
Graphics object consisting of 535 graphics primitives
```

Now, what about drawing several alcove walks, and specifying some colors? A single do-it-all plot method would be cumbersome; so instead, it is actually built on top of many methods (see the list below) that can be called independently and combined at will:

```
sage: L.plot_roots() + L.plot_reflection_hyperplanes()
Graphics object consisting of 12 graphics primitives
```

Note: By default the axes are disabled in root system plots since they tend to polute the picture. Annoyingly they come back when combining them. Here is a workaround:

```
sage: p = L.plot_roots() + L.plot_reflection_hyperplanes()
sage: p.axes(False)
sage: p
Graphics object consisting of 12 graphics primitives
```

In order to specify common information for all the pieces of a root system plot (choice of projection, bounding box, color code for the index set, ...), the easiest is to create an option object using `plot_parse_options()`, and pass it down to each piece. We use this to plot our two walks:

```
sage: plot_options = L.plot_parse_options(bounding_box=[[-2,5],[-2,6]])
sage: w2 = [2,1,2,0,2,0,2,1,2,0,1,2,1,2,1,0,1,2,0,2,0,1,2,0,2]
sage: p = L.plot_alcoves(plot_options=plot_options) # long time
sage: p += L.plot_alcove_walk(w1, color="green", plot_options=plot_options)
sage: p += L.plot_alcove_walk(w2, color="orange", plot_options=plot_options)
sage: p
Graphics object consisting of ... graphics primitives
```

And another with some foldings:

```
sage: p += L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],
...                           foldings= [False, False, True, False, False, False, True, False, True,
...                           color="purple")
sage: p.axes(False)
sage: p.show(figsize=20)
```

Here we show a weight at level 0 and the reduced word implementing the translation by this weight:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: P = RootSystem(["A",2,1]).weight_space(extended=True)
sage: Lambda = P.fundamental_weights()
sage: t = 6*Lambda[1] - 2*Lambda[2] - 4*Lambda[0]
sage: walk = L.reduced_word_of_translation(L(t))
sage: plot_options = L.plot_parse_options(bounding_box=[[-2,5],[-2,5]])
sage: p = L.plot(plot_options=plot_options)        # long time
sage: p += L.plot_alcove_walk(walk, color="green", plot_options=plot_options)
sage: p += plot_options.family_of_vectors({t: L(t)})
sage: plot_options.finalize(p)
Graphics object consisting of ... graphics primitives
sage: p
Graphics object consisting of ... graphics primitives
```

Note that the coloring of the translated alcove does not match with that of the fundamental alcove: the translation actually lives in the extended Weyl group and is the composition of the simple reflections indexed by the alcove walk together with a rotation implementing an automorphism of the Dynkin diagram.

We conclude with a rank $3 + 1$ alcove walk:

```
sage: L = RootSystem(["B",3,1]).ambient_space()
sage: w3 = [0,2,1,3,2,0,2,1,0,2,3,1,2,1,3,2,0,2,0,1,2,0]
sage: L.plot_fundamental_weights() + L.plot_reflection_hyperplanes(bounding_box=2) + L.plot_alcove_wa
Graphics3d Object
```

Exercise

1. Draw the tiling of 3D space by the fundamental polygons for types A,B,C,D. Hints: use the `wireframe` option of `RootLatticeRealizations.ParentMethods.plot_alcoves()` and the `color` option of `plot()` to only draw the alcove facets indexed by 0.

Solution

```
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: alcoves = cartesian_product([[0,1],[0,1],[0,1]])
sage: color = lambda i: "black" if i==0 else None
sage: L.plot_alcoves(alcoves=alcoves, color=color, bounding_box=10,wireframe=True).show(frame=False)
```

Hand drawing on top of a root system plot (aka Coxeter graph paper)

Taken from John Stembridge's excellent data archive:

"If you've ever worked with affine reflection groups, you've probably wasted lots of time drawing the reflecting hyperplanes of the rank 2 groups on scraps of paper. You may also have wished you had pads of graph paper with these lines drawn in for you. If so, you've come to the right place. Behold! Coxeter graph paper!".

Now you can create your own customized color Coxeter graph paper:

```
sage: L = RootSystem(["C",2,1]).ambient_space()
sage: p = L.plot(bounding_box=[[-8,9],[-5,7]], coroots="simple") # long time (10 s)
sage: p
Graphics object consisting of ... graphics primitives
```

By default Sage's plot are bitmap pictures which would come out ugly if printed on paper. Instead, we recommend saving the picture in postscript or svg before printing it:

```
sage: p.save("C21paper.eps")        # not tested
```

Note: Drawing pictures with a large number of alcoves is currently somewhat ridiculously slow. This is due to the use of generic code that works uniformly in all dimension rather than taylor-made code for 2D. Things should improve with the upcoming fast interface to the PPL library (see e.g. trac ticket #12553).

Drawing custom objects on top of a root system plot

So far so good. Now, what if one wants to draw, on top of a root system plot, some object for which there is no preexisting plot method? Again, the `plot_options` object come in handy, as it can be used to compute appropriate coordinates. Here we draw the permutohedron, that is the Cayley graph of the symmetric group W, by positioning each element w at $w(\rho)$, where ρ is in the fundamental alcove:

```
sage: L = RootSystem(["A",2]).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_alcoves()
```

```
sage: p += g.plot(pos = positions, vertex_size=0,
...               color_by_label=plot_options.color)
sage: p.axes(False)
sage: p
Graphics object consisting of 30 graphics primitives
```

Todo

Could we have nice LaTeX labels in this graph?

The same picture for A_3 gives a nice 3D permutohedron:

```
sage: L = RootSystem(["A",3]).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_roots()
sage: p += g.plot3d(pos3d = positions, color_by_label=plot_options.color)
sage: p
Graphics3d Object
```

Exercises

1. Locate the identity element of W in the previous picture
2. Rotate the picture appropriately to highlight the various symmetries of the permutohedron.
3. Make a function out of the previous example, and explore the Cayley graphs of all rank 2 and 3 Weyl groups.
4. Draw the root poset for type B_2 and B_3
5. Draw the root poset for type E_8 to recover the picture from Wikipedia article File:E8_3D.png

Similarly, we display a crystal graph by positioning each element according to its weight:

```
sage: C = crystals.Tableaux(["A",2], shape=[4,2])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()

sage: g = C.digraph()
sage: positions = {x: plot_options.projection(x.weight()) for x in C}
sage: p = L.plot()
sage: p += g.plot(pos = positions,
...               color_by_label=plot_options.color, vertex_size=0)
sage: p.axes(False)
sage: p.show(figsize=15)
```

Note: In the above picture, many pairs of tableaux have the same weight and are thus superposed (look for example near the center). Some more layout logic would be needed to separate those nodes properly, but the foundations are laid firmly and uniformly accross all types of root systems for writing such extensions.

Here is an analogue picture in 3D:

```
sage: C = crystals.Tableaux(["A",3], shape=[3,2,1])
sage: L = C.weight_lattice_realization()
```

```
sage: plot_options = L.plot_parse_options()
sage: g = C.digraph()
sage: positions = {x:plot_options.projection(x.weight()) for x in C}
sage: p = L.plot(reflection_hyperplanes=False, fundamental_weights=False)
sage: p += g.plot3d(pos3d = positions, vertex_labels=True,
...                 color_by_label=plot_options.color, edge_labels=True)
sage: p
Graphics3d Object
```

Exercise

Explore the previous picture and notice how the edges of the crystal graph are parallel to the simple roots.

Enjoy and please post your best pictures on the Sage-Combinat wiki.

class sage.combinat.root_system.plot.**PlotOptions**(*space*, *projection=True*, *bounding_box=3*, *color=<bound method type.color of <class 'sage.combinat.root_system.cartan_type.CartanTypeFactory'>>*, *labels=True*, *level=None*, *affine=None*, *arrowsize=5*)

A class for plotting options for root lattice realizations.

See also:

- RootLatticeRealizations.ParentMethods.plot() for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

color(*i*)

Return the color to be used for objects indexed by i.

INPUT:

- i – an index

See also:

index_of_object()

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.color(1)
'blue'
sage: options.color(2)
'red'
sage: for alpha in L.roots():
...       print alpha, options.color(alpha)
alpha[1]             blue
alpha[2]             red
alpha[1] + alpha[2]  black
-alpha[1]            black
-alpha[2]            black
-alpha[1] - alpha[2] black
```

cone(*rays=[ ], lines=[ ], color='black', thickness=1, alpha=1, wireframe=False, label=None, draw_degenerate=True, as_polyhedron=False*)

Return the cone generated by the given rays and lines.

INPUT:

- `rays`, `lines` – lists of elements of the root lattice realization (default: `[]`)
- `color` – a color (default: `"black"`)
- `alpha` – a number in the interval $[0, 1]$ (default: 1) the desired transparency
- `label` – an object to be used as for this cone. The label itself will be constructed by calling `latex()` or `repr()` on the object depending on the graphics backend.
- `draw_degenerate` – a boolean (default: `True`) whether to draw cones with a degenerate intersection with the bounding box
- `as_polyhedron` – a boolean (default: `False`) whether to return the result as a polyhedron, without clipping it to the bounding box, and without making a plot out of it (for testing purposes)

OUTPUT:

A graphic object, a polyhedron, or `0`.

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2)
sage: p
Graphics object consisting of 2 graphics primitives
sage: list(p)
[Polygon defined by 4 points,
 Text '$2$' at the point (3.15,3.15)]
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2, as_polyhedron=
A 2-dimensional polyhedron in ZZ^2 defined as the convex hull of 1 vertex, 1 ray, 1 line
```

An empty result, being outside of the bounding box:

```
sage: options = L.plot_parse_options(labels=True, bounding_box=[[-10,-9]]*2)
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2)
0
```

Test that the options are properly passed down:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: p = options.cone(rays=[alpha[1]+alpha[2]], color='green', label=2, thickness=4, alpha=
sage: list(p)
[Line defined by 2 points, Text '$2$' at the point (3.15,3.15)]
sage: sorted(p[0].options().items())
[('alpha', 0.500000000000000), ('legend_color', None),
 ('legend_label', None), ('rgbcolor', 'green'), ('thickness', 4),
 ('zorder', 1)]
```

This method is tested indirectly but extensively by the various plot methods of root lattice realizations.

empty(**args*)

Return an empty plot.

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options(labels=True)
```

This currently returns `int(0)`:

```
sage: options.empty()
0
```

This is not a plot, so may cause some corner cases. On the other hand, 0 behaves as a fast neutral element, which is important given the typical idioms used in the plotting code:

```
sage: p = point([0,0])
sage: p + options.empty() is p
True
```

family_of_vectors(*vectors*)

Return a plot of a family of vectors.

INPUT:

- `vectors` – family or vectors in `self`

The vectors are labelled by their index.

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.family_of_vectors(alpha); p
Graphics object consisting of 4 graphics primitives
sage: list(p)
[Arrow from (0.0,0.0) to (1.0,0.0),
 Text '$1$' at the point (1.05,0.0),
 Arrow from (0.0,0.0) to (0.0,1.0),
 Text '$2$' at the point (0.0,1.05)]
```

Handling of colors and labels:

```
sage: color=lambda i: "purple" if i==1 else None
sage: options = L.plot_parse_options(labels=False, color=color)
sage: p = options.family_of_vectors(alpha)
sage: list(p)
[Arrow from (0.0,0.0) to (1.0,0.0)]
sage: p[0].options()['rgbcolor']
'purple'
```

Matplotlib emits a warning for arrows of length 0 and draws nothing anyway. So we do not draw them at all:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: Lambda = L.fundamental_weights()
sage: p = options.family_of_vectors(Lambda); p
Graphics object consisting of 5 graphics primitives
sage: list(p)
[Text '$0$' at the point (0.0,0.0),
 Arrow from (0.0,0.0) to (0.5,0.866024518389),
 Text '$1$' at the point (0.525,0.909325744308),
 Arrow from (0.0,0.0) to (-0.5,0.866024518389),
 Text '$2$' at the point (-0.525,0.909325744308)]
```

finalize(*G*)

Finalize a root system plot.

INPUT:

- G – a root system plot or 0

This sets the aspect ratio to 1 and remove the axes. This should be called by all the user-level plotting methods of root systems. This will become mostly obsolete when customization options won't be lost anymore upon addition of graphics objects and there will be a proper empty object for 2D and 3D plots.

EXAMPLES:

```
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: p = L.plot_roots(plot_options=options)
sage: p += L.plot_coroots(plot_options=options)
sage: p.axes()
True
sage: p = options.finalize(p)
sage: p.axes()
False
sage: p.aspect_ratio()
1.0

sage: options = L.plot_parse_options(affine=False)
sage: p = L.plot_roots(plot_options=options)
sage: p += point([[1,1,0]])
sage: p = options.finalize(p)
sage: p.aspect_ratio()
[1.0, 1.0, 1.0]
```

If the input is 0, this returns an empty graphics object:

```
sage: type(options.finalize(0))
<class 'sage.plot.plot3d.base.Graphics3dGroup'>

sage: options = L.plot_parse_options()
sage: type(options.finalize(0))
<class 'sage.plot.graphics.Graphics'>
sage: list(options.finalize(0))
[]
```

in_bounding_box(*x*)

Return whether x is in the bounding box.

INPUT:

- x – an element of the root lattice realization

This method is currently one of the bottlenecks, and therefore cached.

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: options.in_bounding_box(alpha[1])
True
sage: options.in_bounding_box(3*alpha[1])
False
```

index_of_object(*i*)

Try to return the node of the Dynkin diagram indexing the object i.

OUTPUT: a node of the Dynkin diagram or `None`

EXAMPLES:

```
sage: L = RootSystem(["A",3]).root_lattice()
sage: alpha = L.simple_roots()
sage: omega = RootSystem(["A",3]).weight_lattice().fundamental_weights()
sage: options = L.plot_parse_options(labels=False)
sage: options.index_of_object(3)
3
sage: options.index_of_object(alpha[1])
1
sage: options.index_of_object(omega[2])
2
sage: options.index_of_object(omega[2]+omega[3])
sage: options.index_of_object(30)
sage: options.index_of_object("bla")
```

intersection_at_level_1(*x*)

Return `x` scaled at the appropriate level, if level is set; otherwise return `x`.

INPUT:

- `x` – an element of the root lattice realization

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).weight_space()
sage: options = L.plot_parse_options()
sage: options.intersection_at_level_1(L.rho())
1/3*Lambda[0] + 1/3*Lambda[1] + 1/3*Lambda[2]

sage: options = L.plot_parse_options(affine=False, level=2)
sage: options.intersection_at_level_1(L.rho())
2/3*Lambda[0] + 2/3*Lambda[1] + 2/3*Lambda[2]
```

When `level` is not set, `x` is returned:

```
sage: options = L.plot_parse_options(affine=False)
sage: options.intersection_at_level_1(L.rho())
Lambda[0] + Lambda[1] + Lambda[2]
```

projection(*v*)

Return the projection of `v`.

INPUT:

- `x` – an element of the root lattice realization

OUTPUT:

An immutable vector with integer or rational coefficients.

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: options.projection(L.rho())
(0, 989/571)

sage: options = L.plot_parse_options(projection=False)
```

```
sage: options.projection(L.rho())
(2, 1, 0)
```

reflection_hyperplane(*coroot*, *as_polyhedron=False*)

Return a plot of the reflection hyperplane indexed by this coroot.

- `coroot` – a coroot

EXAMPLES:

```
sage: L = RootSystem(["B",2]).weight_space()
sage: alphacheck = L.simple_coroots()
sage: options = L.plot_parse_options()
sage: H = options.reflection_hyperplane(alphacheck[1]); H
Graphics object consisting of 2 graphics primitives
```

TESTS:

```
sage: print H.description()
Text '$H_{\alpha^\vee_{1}}$' at the point (0.0,3.15)
Line defined by 2 points: [(0.0, 3.0), (0.0, -3.0)]

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: alphacheck = L.simple_coroots()
sage: options = L.plot_parse_options()
sage: H = options.reflection_hyperplane(alphacheck[1], as_polyhedron=True); H
A 2-dimensional polyhedron in QQ^3 defined as the convex hull of 1 vertex and 2 lines
sage: H.lines()
(A line in the direction (0, 0, 1), A line in the direction (0, 1, 0))
sage: H.vertices()
(A vertex at (0, 0, 0),)

sage: all(options.reflection_hyperplane(c, as_polyhedron=True).dim() == 2
...       for c in alphacheck)
True
```

Todo

Display the periodic orientation by adding a $+$ and a $-$ sign close to the label. Typically by using the associated root to shift a bit from the vertex upon which the hyperplane label is attached.

---

text(*label*, *position*, *rgbcolor=(0, 0, 0)*)

Return text widget with label `label` at position `position`

INPUT:

- `label` – a string, or a Sage object upon which latex will be called
- `position` – a position
- `rgbcolor` – the color as an RGB tuple

EXAMPLES:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: list(options.text("coucou", [0,1]))
[Text 'coucou' at the point (0.0,1.0)]
sage: list(options.text(L.simple_root(1), [0,1]))
[Text '$\alpha_{1}$' at the point (0.0,1.0)]
sage: list(options.text(L.simple_root(2), [1,0], rgbcolor=(1,0.5,0)))
```

```
[Text '$\alpha_{2}$' at the point (1.0,0.0)]

sage: options = RootSystem(["A",2]).root_lattice().plot_parse_options(labels=False)
sage: options.text("coucou", [0,1])
0

sage: options = RootSystem(["B",3]).root_lattice().plot_parse_options()
sage: print options.text("coucou", [0,1,2]).x3d_str()
<Transform translation='0 1 2'>
<Shape><Text string='coucou' solid='true'/><Appearance><Material diffuseColor='0.0 0.0 0.0'

</Transform>
```

thickness(*i*)

Return the thickness to be used for lines indexed by i.

INPUT:

- `i` – an index

See also:

`index_of_object()`

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.thickness(0)
2
sage: options.thickness(1)
1
sage: options.thickness(2)
1
sage: for alpha in L.simple_roots():
....:     print alpha, options.thickness(alpha)
alpha[0] 2
alpha[1] 1
alpha[2] 1
```

sage.combinat.root_system.plot.**barycentric_projection_matrix**(*n*, *angle=0*)

Returns a family of $n+1$ vectors evenly spaced in a real vector space of dimension n

Those vectors are of norm 1, the scalar product between any two vector is $1/n$, thus the distance between two tips is constant.

The family is built recursively and uniquely determined by the following property: the last vector is $(0, \ldots, 0, -1)$, and the projection of the first n vectors in dimension $n-1$, after appropriate rescaling to norm 1, retrieves the family for $n-1$.

OUTPUT:

A matrix with $n+1$ columns of height n with rational or symbolic coefficients.

EXAMPLES:

One vector in dimension 0:

```
sage: from sage.combinat.root_system.root_lattice_realizations import barycentric_projection_mat
sage: m = barycentric_projection_matrix(0); m
[]
```

```
sage: matrix(QQ,0,1).nrows()
0
sage: matrix(QQ,0,1).ncols()
1
```

Two vectors in dimension 1:

```
sage: barycentric_projection_matrix(1)
[ 1 -1]
```

Three vectors in dimension 2:

```
sage: barycentric_projection_matrix(2)
[ 1/2*sqrt(3) -1/2*sqrt(3)            0]
[         1/2          1/2           -1]
```

Four vectors in dimension 3:

```
sage: m = barycentric_projection_matrix(3); m
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2)                    0                    0]
[         1/3*sqrt(2)          1/3*sqrt(2)         -2/3*sqrt(2)                    0]
[                1/3                  1/3                  1/3                   -1]
```

The columns give four vectors that sum up to zero:

```
sage: sum(m.columns())
(0, 0, 0)
```

and have regular mutual angles:

```
sage: m.transpose()*m
[   1 -1/3 -1/3 -1/3]
[-1/3    1 -1/3 -1/3]
[-1/3 -1/3    1 -1/3]
[-1/3 -1/3 -1/3    1]
```

Here is a plot of them:

```
sage: sum(arrow((0,0,0),x) for x in m.columns())
Graphics3d Object
```

For 2D drawings of root systems, it is desirable to rotate the result to match with the usual conventions:

```
sage: barycentric_projection_matrix(2, angle=2*pi/3)
[         1/2          -1         1/2]
[ 1/2*sqrt(3)           0 -1/2*sqrt(3)]
```

TESTS:

```
sage: for n in range(1, 7):
...       m = barycentric_projection_matrix(n)
...       assert sum(m.columns()).is_zero()
...       assert matrix(QQ, n+1,n+1, lambda i,j: 1 if i==j else -1/n) == m.transpose()*m
```

5.1.207 Group algebras of root lattice realizations

class sage.combinat.root_system.root_lattice_realization_algebras.**Algebras**(*category*, **args*)

Bases: sage.categories.algebra_functor.AlgebrasCategory

The category of group algebras of root lattice realizations.

This includes typically weight rings (group algebras of weight lattices).

TESTS:

```
sage: for ct in CartanType.samples(crystallographic=True): # long time
....:     TestSuite(RootSystem(ct).root_lattice().algebra(QQ)).run()
```

class ElementMethods

acted_upon(*w*)

Implements the action of `w` on `self`.

INPUT:

- `w` – an element of the Weyl group acting on the underlying weight lattice realization

EXAMPLES:

```
sage: L = RootSystem(["A",3]).ambient_space()
sage: W = L.weyl_group()
sage: M = L.algebra(QQ['q','t'])
sage: m = M.an_element(); m  # TODO: investigate why we don't get something more interes
B[(2, 2, 3, 0)]
sage: m = (m+1)^2; m
B[(0, 0, 0, 0)] + 2*B[(2, 2, 3, 0)] + B[(4, 4, 6, 0)]
sage: w = W.an_element(); w.reduced_word()
[1, 2, 3]
sage: m.acted_upon(w)
B[(0, 0, 0, 0)] + 2*B[(0, 2, 2, 3)] + B[(0, 4, 4, 6)]
```

expand(*alphabet*)

Expand `self` into variables in the `alphabet`.

INPUT:

- `alphabet` – a non empty list/tuple of (invertible) variables in a ring to expand in

EXAMPLES:

```
sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: p = KL.an_element() + KL.sum_of_monomials(L.some_elements()); p
B[(1, 0, 0)] + B[(1, -1, 0)] + B[(1, 1, 0)] + 2*B[(2, 2, 3)] + B[(0, 1, -1)]
sage: F = LaurentPolynomialRing(QQ, 'x,y,z')
sage: p.expand(F.gens())
2*x^2*y^2*z^3 + x*y + x + y*z^-1 + x*y^-1
```

TESTS:

```
sage: type(p.expand(F.gens()))
<type 'sage.rings.polynomial.laurent_polynomial.LaurentPolynomial_mpair'>

sage: p = KL.zero()
sage: p.expand(F.gens())
0
sage: type(p.expand(F.gens()))
<type 'sage.rings.polynomial.laurent_polynomial.LaurentPolynomial_mpair'>
```

class `Algebras`**.ParentMethods**

T0_check_on_basis(*q1*, *q2*, *convention='antidominant'*)

Return the $T_0^\vee$ operator acting on the basis.

This implements the formula for $T_{0'}$ in Section 6.12 of [Haiman06].

REFERENCES:

Warning: The current implementation probably returns just nonsense, if the convention is not "dominant".

EXAMPLES:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1,q2 = K.gens()

sage: L = RootSystem(["A",1,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())
(q1+q2)*B[(0, 0)] + q1*B[(1, -1)]

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L0.fundamental_weights()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: f(L0.zero())       # not checked
(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]
```

The following results have not been checked:

```
sage: for x in some_weights:
....:     print x, ": ", f(x)
(1, 0, 0, 0) :  q1*B[(1, 0, 0, 0)]
(1, 1, 0, 0) :  q1*B[(1, 1, 0, 0)]
(1, 1, 1, 0) :  q1*B[(1, 1, 1, 0)]
```

Some examples for type $B_2^{(1)}$ dual:

```
sage: L = RootSystem("B2~*").ambient_space()
sage: L0 = L.classical()
sage: e = L.basis()
sage: K = QQ['q,u'].fraction_field()
sage: q,u = K.gens()
sage: q1 = u
sage: q2 = -1/u
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")
```

Direct calculation:

```
sage: T.Tw(0)(KL0.monomial(L0([0,0])))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
sage: KL.T0_check_on_basis(q1,q2, convention="dominant")(L0([0,0]))
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
```

Step by step calculation, comparing by hand with Mark Shimozono:

```
sage: res = T.Tw(2)(KL0.monomial(L0([0,0]))); res
u*B[(0, 0)]
sage: res = res * KL0.monomial(L0([-1,1])); res
u*B[(-1, 1)]
sage: res = T.Tw_inverse(1)(res); res
(u^2-1)*B[(0, 0)] + u^2*B[(1, -1)]
```

```
sage: res = T.Tw_inverse(2)(res); res
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
```

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.cartan_type()
['A', 2, 1]
sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
sage: A.cartan_type()
['B', 2]
```

classical()

Return the group algebra of the corresponding classical lattice.

EXAMPLES:

```
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: KL.classical()
Group algebra of the Ambient space of the Root system of type ['A', 2] over Rational Fie
```

demazure_lusztig_operator_on_basis(*weight*, *i*, *q1*, *q2*, *convention='antidominant'*)

Return the result of applying the i-th Demazure-Lusztig operator on `weight`.

INPUT:

- `weight` – an element λ of the weight lattice
- `i` – an element of the index set
- `q1, q2` – two elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

See `demazure_lusztig_operators()` for the details.

EXAMPLES:

```
sage: L = RootSystem(["A",1]).ambient_space()
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, q1, q2)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(3, 0)]
```

At $q_1 = 1$ and $q_2 = 0$ we recover the action of the isobaric divided differences π_i:

```
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0)
-B[(1, 2)] - B[(2, 1)]
```

Or $1 - \pi_i$ for `bar=True`:

```
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0, convention="bar")
0
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0, convention="bar")
-B[(1, 2)] - B[(2, 1)] - B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0, convention="bar")
```

```
B[(1, 2)] + B[(2, 1)] + B[(0, 3)]
```

At $q_1 = 1$ and $q_2 = -1$ we recover the action of the simple reflection s_i:

```
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, -1)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, -1)
B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, -1)
B[(3, 0)]
```

demazure_lusztig_operator_on_classical_on_basis(*weight*, *i*, *q*, *q1*, *q2*, *convention='antidominant'*)

Return the result of applying the i-th Demazure-Lusztig operator on the classical weight `weight` embedded at level 0.

INPUT:

- `weight` – a classical weight λ
- `i` – an element of the index set
- `q1, q2` – two elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

See `demazure_lusztig_operators()` for the details.

Todo

- Optimize the code to only do the embedding/projection for T_0
- Add an option to specify at which level one wants to work. Currently this is level 0.

EXAMPLES:

```
sage: L = RootSystem(["A",1,1]).ambient_space()
sage: L0 = L.classical()
sage: K = QQ['q,q1,q2']
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = L0.algebra(K)
```

These operators coincide with the usual Demazure-Lusztig operators:

```
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 1, q, q1, q2)
q1*B[(2, 2)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((2,2)), 1, q1, q2)
q1*B[(2, 2)]

sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 1, q, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

except that we now have an action of T_0, which introduces some q s:

```
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 0, q, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 0, q, q1, q2)
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]
```

demazure_lusztig_operators(*q1*, *q2*, *convention='antidominant'*)

Return the Demazure-Lusztig operators acting on `self`.

INPUT:

- `q1, q2` – two elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

If R is the parent weight ring, the Demazure-Lusztig operator T_i is the linear map $R \to R$ obtained by interpolating between the isobaric divided difference operator π_i (see `isobaric_divided_difference_on_basis()`) and the simple reflection s_i.

$$(q_1 + q_2)\pi_i - q_2 s_i$$

The Demazure-Lusztig operators give the usual representation of the operator T_i of the (affine) Hecke algebra with eigenvalues q_1 and q_2 associated to the Weyl group.

Several variants are available to match with various conventions used in the literature:

- "bar" replaces π_i in the formula above by $\overline{\pi}_i = (1 - \pi_i)$.
- "dominant" conjugates the operator by $x^\lambda \mapsto x^- \lambda$.

The names dominant and antidominant for the conventions were chosen with regards to the nonsymmetric Macdonald polynomials. The Y operators for the Macdonald polynomials in the "dominant" convention satisfy $Y_\lambda = T_{t_\lambda}$ for λ dominant. This is also the convention used in [Haiman06]. For the "antidominant" convention, $Y_\lambda = T_{t_\lambda}$ with λ antidominant.

See also:

- `demazure_lusztig_operator_on_basis()`.
- `NonSymmetricMacdonaldPolynomials`.

REFERENCES:

EXAMPLES:

```
sage: L = RootSystem(["A",1]).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: x = KL.monomial(L((3,0)))
sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: Tbar[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q1-2*q2)*B[(0, 3)]
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[(3, 0)] + (-2*q2)*B[(0, 3)]
sage: Tdominant[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(0, 3)]

sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[(0, 0)] - 1/q2*B[(1, -1)]
```

We repeat similar computation in the affine setting:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: e = L.basis()
sage: x = KL.monomial(3*e[0])
sage: T[1](x)
(q1+q2)*B[e[0] + 2*e[1]] + (q1+q2)*B[2*e[0] + e[1]] + (q1+q2)*B[3*e[0]] + q1*B[3*e[1]]
sage: Tbar[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q1-2*q2)*B[3*e[1]]
```

```
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[3*e[0]] + (-2*q2)*B[3*e[1]]
sage: Tdominant[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]] + (-q2)*B[3*e[1]]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[0] - 1/q2*B[e[0] - e[1]]
```

One can obtain iterated operators by passing a reduced word or an element of the Weyl group:

```
sage: T[1,2](x)
(q1^2+2*q1*q2+q2^2)*B[e[0] + e[1] + e[2]] +
(q1^2+2*q1*q2+q2^2)*B[e[0] + 2*e[1]] +
(q1^2+q1*q2)*B[e[0] + 2*e[2]] + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + e[1]] +
(q1^2+q1*q2)*B[2*e[0] + e[2]] + (q1^2+q1*q2)*B[3*e[0]] +
(q1^2+q1*q2)*B[e[1] + 2*e[2]] + (q1^2+q1*q2)*B[2*e[1] + e[2]] +
(q1^2+q1*q2)*B[3*e[1]] + q1^2*B[3*e[2]]
```

and use that to check, for example, the braid relations:

```
sage: T[1,2,1](x) - T[2,1,2](x)
0
```

The operators satisfy the relations of the affine Hecke algebra with parameters q_1, q_2:

```
sage: T._test_relations()
sage: Tdominant._test_relations()
sage: Tbar._test_relations() #-q2,q1+2*q2   # todo: not implemented: set the appropriate
```

And the $\bar{T}$ are basically the inverses of the T s:

```
sage: Tinv = KL.demazure_lusztig_operators(2/q1+1/q2,-1/q1,convention="bar")
sage: [Tinv[1](T[1](x))-x for x in KL.some_elements()]
[0, 0, 0, 0, 0, 0, 0]
```

We check that $\Lambda_1 - \Lambda_0$ is an eigenvector for the Y s in affine type:

```
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2=K.gens()
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L0 = L.classical()
sage: Lambda = L.fundamental_weights()
sage: alphacheck = L0.simple_coroots()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().alpha() # alpha of coroot lattice is alphacheck
sage: alphacheck
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: x = KL.monomial(Lambda[1]-Lambda[0]); x
B[e[0]]
```

In fact it is not exactly an eigenvector, but the extra 'delta' term is to be interpreted as a q parameter:

```
sage: Y[alphacheck[0]](KL.one())
q2^2/q1^2*B[0]
sage: Y[alphacheck[1]](x)
((-q2^2)/(-q1^2))*B[e[0] - e['delta']]
sage: Y[alphacheck[2]](x)
(q1/(-q2))*B[e[0]]
sage: KL.q_project(Y[alphacheck[1]](x),q)
((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]

sage: KL.q_project(x, q)
B[(1, 0, 0)]
```

```
sage: KL.q_project(Y[alphacheck[0]](x),q)
((-q*q1)/q2)*B[(1, 0, 0)]
sage: KL.q_project(Y[alphacheck[1]](x),q)
((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]
sage: KL.q_project(Y[alphacheck[2]](x),q)
(q1/(-q2))*B[(1, 0, 0)]
```

We now check systematically that the Demazure-Lusztig operators satisfy the relations of the Iwahori-Hecke algebra:

```
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(crystallographic=True): # long time 12s
....:     L = RootSystem(cartan_type).root_lattice()
....:     KL = L.algebra(K)
....:     T = KL.demazure_lusztig_operators(q1,q2)
....:     T._test_relations()

sage: for cartan_type in CartanType.samples(crystallographic=True): # long time 12s
....:     L = RootSystem(cartan_type).weight_lattice()
....:     KL = L.algebra(K)
....:     T = KL.demazure_lusztig_operators(q1,q2)
....:     T._test_relations()
```

Recall that the Demazure-Lusztig operators are only defined when all monomials belong to the weight lattice. Thus, in the group algebra of the ambient space, we need to specify explicitly the elements on which to run the tests:

```
sage: for cartan_type in CartanType.samples(crystallographic=True): # long time 12s
....:     L = RootSystem(cartan_type).ambient_space()
....:     KL = L.algebra(K)
....:     weight_lattice = RootSystem(cartan_type).weight_lattice(extended=L.is_extended(
....:     elements = [ KL.monomial(L(weight)) for weight in weight_lattice.some_elements(
....:     T = KL.demazure_lusztig_operators(q1,q2)
....:     T._test_relations(elements=elements)
```

demazure_lusztig_operators_on_classical(*q*, *q1*, *q2*, *convention='antidominant'*)

Return the Demazure-Lusztig operators acting at level 1 on `self.classical()`.

INPUT:

- `q, q1, q2` – three elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

Let KL be the group algebra of an affine weight lattice realization L. The Demazure-Lusztig operators for KL act on the group algebra of the corresponding classical weight lattice by embedding it at level 1, and projecting back.

See also:

- `demazure_lusztig_operators()`.
- `demazure_lusztig_operator_on_classical_on_basis()`.
- `q_project()`

EXAMPLES:

```
sage: L = RootSystem(["A",1,1]).ambient_space()
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1, q2)
```

```
sage: x = KL0.monomial(L0((3,0))); x
B[(3, 0)]
```

For $T_1, \ldots$ we recover the usual Demazure-Lusztig operators:

```
sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

For T_0, we can note that, in the projection, δ is mapped to q:

```
sage: T[0](x)
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]
```

Note that there is no translation part, and in particular 1 is an eigenvector for all T_i's:

```
sage: T[0](KL0.one())
q1*B[(0, 0)]
sage: T[1](KL0.one())
q1*B[(0, 0)]

sage: Y = T.Y()
sage: alphacheck=Y.keys().simple_roots()
sage: Y[alphacheck[0]](KL0.one())
((-q2)/(q*q1))*B[(0, 0)]
```

Matching with Ion Bogdan's hand calculations from 3/15/2013:

```
sage: L = RootSystem(["A",1,1]).weight_space(extended=True)
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: L0 = KL0.basis().keys()
sage: omega = L0.fundamental_weights()
sage: T = KL.demazure_lusztig_operators_on_classical(q, u, -1/u, convention="dominant")
sage: Y = T.Y()
sage: alphacheck = Y.keys().simple_roots()

sage: Ydelta = Y[Y.keys().null_root()]
sage: Ydelta.word, Ydelta.signs, Ydelta.scalar
((), (), 1/q)

sage: Y1 = Y[alphacheck[1]]
sage: Y1.word, Y1.signs, Y1.scalar # This is T_0 T_1 (T_1 acts first, then T_0); Ion get
((1, 0), (1, 1), 1)

sage: Y0 = Y[alphacheck[0]]
sage: Y0.word, Y0.signs, Y0.scalar # This is 1/q T_1^-1 T_0^-1
((0, 1), (-1, -1), 1/q)
```

Note that the following computations use the "dominant" convention:

```
sage: T0 = T.Tw(0)
sage: T0(KL0.monomial(omega[1]))
q*u*B[-Lambda[1]] + ((u^2-1)/u)*B[Lambda[1]]
sage: T0(KL0.monomial(2*omega[1]))
((q*u^2-q)/u)*B[0] + q^2*u*B[-2*Lambda[1]] + ((u^2-1)/u)*B[2*Lambda[1]]

sage: T0(KL0.monomial(-omega[1]))
1/(q*u)*B[Lambda[1]]
sage: T0(KL0.monomial(-2*omega[1]))
((-u^2+1)/(q*u))*B[0] + 1/(q^2*u)*B[2*Lambda[1]]
```

demazure_operators()

Return the Demazure operators acting on `self`.

The i-th Demazure operator is defined by:

$$\pi_i = \frac{1 - e^{-\alpha_i} s_i}{1 - e^{-\alpha_i}}$$

It acts on e^λ, for λ a weight, by:

$$\pi_i e^\lambda = \frac{e^\lambda - e^{-\alpha_i + s_i \lambda}}{1 - e^{-\alpha_i}}$$

This matches with Lascoux' definition [Lascoux2003] of π_i, and with the i-th Demazure operator of [Kumar1987], which also works for general Kac-Moody types.

REFERENCES:

EXAMPLES:

We compute some Schur functions, as images of dominant monomials under the action of the maximal isobaric divided difference Δ_{w_0}:

```
sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: w0 = tuple(L.weyl_group().long_element().reduced_word())
sage: pi = KL.demazure_operators()
sage: pi0 = pi[w0]
sage: pi0(KL.monomial(L((2,1))))
2*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, 1)] + B[(0, 1, 2)
```

Let us make the result into an actual polynomial:

```
sage: P = QQ['x,y,z']
sage: pi0(KL.monomial(L((2,1)))).expand(P.gens())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

This is indeed a Schur function:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3, P.gens())
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

Let us check this systematically on Schur functions of degree 6:

```
sage: for p in Partitions(6, max_length=3).list():
....:     assert s.monomial(p).expand(3, P.gens()) == pi0(KL.monomial(L(tuple(p)))).expa
```

We check systematically that these operators satisfy the Iwahori-Hecke algebra relations:

```
sage: for cartan_type in CartanType.samples(crystallographic=True): # long time 12s
....:     L = RootSystem(cartan_type).weight_lattice()
....:     KL = L.algebra(QQ)
....:     T = KL.demazure_operators()
....:     T._test_relations()

sage: L = RootSystem(['A',1,1]).weight_lattice()
sage: KL = L.algebra(QQ)
sage: T = KL.demazure_operators()
sage: T._test_relations()
```

Warning: The Demazure operators are only defined if all the elements in the support have integral scalar products with the coroots (basically, they are in the weight lattice). Otherwise an error is raised:

```
sage: L = RootSystem(CartanType(["G",2]).dual()).ambient_space()
sage: KL = L.algebra(QQ)
sage: pi = KL.demazure_operators()
sage: pi[1](KL.monomial(L([0,0,1])))
Traceback (most recent call last):
...
ValueError: the weight does not have an integral scalar product with the coroot
```

divided_difference_on_basis(*weight*, *i*)

Return the result of applying the i-th divided difference on `weight`.

INPUT:

- `weight` – a weight
- `i` – an element of the index set

Todo

type free definition (Viviane's definition uses that we are in the ambient space)

EXAMPLES:

```
sage: L = RootSystem(["A",1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.divided_difference_on_basis(L((2,2)), 1) # todo: not implemented
0
sage: KL.divided_difference_on_basis(L((3,0)), 1) # todo: not implemented
B[(2, 0)] + B[(1, 1)] + B[(0, 2)]
sage: KL.divided_difference_on_basis(L((0,3)), 1) # todo: not implemented
-B[(2, 0)] - B[(1, 1)] - B[(0, 2)]
```

In type A and in the ambient lattice, we recover the usual action of divided differences polynomials:

```
sage: x,y = QQ['x,y'].gens()
sage: d = lambda p: (p - p(y,x)) / (x-y)
sage: d(x^2*y^2)
0
sage: d(x^3)
x^2 + x*y + y^2
sage: d(y^3)
-x^2 - x*y - y^2
```

from_polynomial(*p*)

Construct an element of `self` from a polynomial p.

INPUT:

- `p` – a polynomial

EXAMPLES:

```
sage: L = RootSystem(["A",2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: x,y,z = QQ['x,y,z'].gens()
sage: KL.from_polynomial(x)
B[(1, 0, 0)]
sage: KL.from_polynomial(x^2*y + 2*y - z)
B[(2, 1, 0)] + 2*B[(0, 1, 0)] - B[(0, 0, 1)]
```

TESTS:

```
sage: KL.from_polynomial(x).leading_support().parent() is L
True
sage: KL.from_polynomial(x-x)
0
sage: KL.from_polynomial(x-x).parent() is KL
True
```

Todo

make this work for Laurent polynomials too

---

isobaric_divided_difference_on_basis(*weight*, *i*)

Return the result of applying the i-th isobaric divided difference on `weight`.

INPUT:

- `weight` – a weight
- `i` – an element of the index set

See also:

`demazure_operators()`

EXAMPLES:

```
sage: L = RootSystem(["A",1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.isobaric_divided_difference_on_basis(L((2,2)), 1)
B[(2, 2)]
sage: KL.isobaric_divided_difference_on_basis(L((3,0)), 1)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.isobaric_divided_difference_on_basis(L((0,3)), 1)
-B[(1, 2)] - B[(2, 1)]
```

In type A and in the ambient lattice, we recover the usual action of divided differences on polynomials:

```
sage: x,y = QQ['x,y'].gens()
sage: d = lambda p: (x*p - (x*p)(y,x)) / (x-y)
sage: d(x^2*y^2)
x^2*y^2
sage: d(x^3)
x^3 + x^2*y + x*y^2 + y^3
sage: d(y^3)
-x^2*y - x*y^2
```

REFERENCES:

q_project(*x*, *q*)

Implement the q-projection morphism from `self` to the group algebra of the classical space.

INPUT:

- `x` – an element of the group algebra of `self`
- `q` – an element of the ground ring

This is an algebra morphism mapping δ to q and X^b to its classical counterpart for the other elements b of the basis of the realization.

EXAMPLES:

```
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
```

```
sage: x = KL.an_element() + KL.monomial(4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta'])
B[2*e[0] + 2*e[1] + 3*e[2]] + B[4*e[1] + 3*e[2] - 2*e['delta'] + e['deltacheck']]
sage: KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]

sage: KL = RootSystem(["BC",3,2]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: x = KL.an_element() + KL.monomial(4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta'])
B[2*e[0] + 2*e[1] + 3*e[2]] + B[4*e[1] + 3*e[2] - 2*e['delta'] + e['deltacheck']]
sage: KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

Warning: Recall that the null root, usually denoted δ, is in fact `a[0]\delta` in Sage's notation, in order to avoid half integer coefficients (this only makes a difference in type BC). Similarly, what's usually denoted q is in fact `q^a[0]` in Sage's notations, to avoid manipulating square roots:

```
sage: KL.q_project(KL.monomial(L.null_root()),q)
q^2*B[(0, 0, 0)]
```

q_project_on_basis(l, q)

Return the monomial $c * cl(l)$ in the group algebra of the classical lattice.

INPUT:

- `l` – an element of the root lattice realization
- `q` – an element of the ground ring

Here, $cl(l)$ is the projection of l in the classical lattice, and c is the coefficient of l in δ.

See also:

`q_project_on_basis()`

EXAMPLES:

```
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(["A",2,1]).ambient_space().algebra(K)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project_on_basis( 4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta'], q)
1/q^2*B[(0, 4, 3)]
```

some_elements()

Return some elements of the algebra `self`.

EXAMPLES:

```
sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.some_elements()
[B[2*e[0] + 2*e[1] + 3*e[2]],
B[-e[0] + e[2] + e['delta']],
B[e[0] - e[1]],
B[e[1] - e[2]],
B[e['deltacheck']],
B[e[0] + e['deltacheck']],
B[e[0] + e[1] + e['deltacheck']]]

sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
```

```
sage: A.some_elements()
[B[2*Lambda[1] + 2*Lambda[2]],
B[2*Lambda[1] - 2*Lambda[2]],
B[-Lambda[1] + 2*Lambda[2]],
B[Lambda[1]],
B[Lambda[2]]]
```

twisted_demazure_lusztig_operator_on_basis(*weight*, *i*, *q1*, *q2*, *convention='antidominant'*)

Return the twisted Demazure-Lusztig operator acting on the basis.

INPUT:

- `weight` – an element λ of the weight lattice
- `i` – an element of the index set
- `q1, q2` – two elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

See also:

`twisted_demazure_lusztig_operators()`

EXAMPLES:

```
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: Lambda = L.classical().fundamental_weights()
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], 1, q1, q2, co
(-q2)*B[(2, 3, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], 2, q1, q2, co
(-q1-q2)*B[(3, 1, 1, 0)] + (-q2)*B[(3, 0, 2, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], 3, q1, q2, co
q1*B[(3, 2, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], 0, q1, q2, co
((q1*q2+q2^2)/q1)*B[(1, 2, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(1, 2, 2, 0)] + q2^2/q1*B[(1, 2,
+ ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 1, 1)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 2, 0)]
+ ((q1*q2+q2^2)/q1)*B[(2, 1, 0, 2)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 2, 1, 0)] + ((q1*q2
```

twisted_demazure_lusztig_operators(*q1*, *q2*, *convention='antidominant'*)

Return the twisted Demazure-Lusztig operators acting on `self`.

INPUT:

- `q1, q2` – two elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

Warning:

- the code is currently only tested for $q_1 q_2 = -1$
- only the "dominant" convention is functional for $i = 0$

For $T_1, \ldots, T_n$, these operators are the usual Demazure-Lusztig operators. On the other hand, the operator T_0 is twisted:

```
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant")
sage: T._test_relations()
```

TESTS:

The following computations were checked with Mark Shimozono for type $A_1^{(1)}$:

```
sage: L = RootSystem(["A",1,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1,q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant")
sage: T._test_relations()
sage: L0 = L.classical()
sage: alpha = L0.simple_roots()
sage: T.Ti_on_basis(L0.zero(), 1)
q1*B[(0, 0)]
sage: T.Ti_inverse_on_basis(L0.zero(), 1)
1/q1*B[(0, 0)]
sage: T.Ti_on_basis(alpha[1], 1)
(-q1-q2)*B[(0, 0)] + (-q2)*B[(-1, 1)]
sage: T.Ti_inverse_on_basis(alpha[1], 1)
((q1+q2)/(q1*q2))*B[(0, 0)] + 1/q1*B[(-1, 1)] + ((q1+q2)/(q1*q2))*B[(1, -1)]
sage: T.Ti_on_basis(L0.zero(), 0)
(q1+q2)*B[(0, 0)] + q1*B[(1, -1)]
```

The next computations were checked with Mark Shimozono for type $A_2^{(1)}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['u'].fraction_field()
sage: u = K.gen()
sage: KL = L.algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(u, ~u, convention="dominant")
sage: T._test_relations()
sage: L0 = L.classical()
sage: KL0 = L0.algebra(K)
sage: alpha = L0.simple_roots()

sage: phi = L0.highest_root(); phi
(1, 0, -1)
sage: phi.to_simple_root(reduced_word=True)
(2, (1,))
sage: res = T.Ti_on_basis(L0([1,0,1]), 1); res
1/u*B[(0, 1, 1)]
sage: res = res * KL0.monomial(-alpha[2]); res
1/u*B[(0, 0, 2)]
sage: res = T.Tw_inverse(2)(res); res
((u^2-1)/u^2)*B[(0, 1, 1)] + B[(0, 2, 0)]
sage: res = T.Tw_inverse(1)(res); res
((u^2-1)/u)*B[(1, 1, 0)] + ((u^2-1)/u)*B[(1, 0, 1)] + u*B[(2, 0, 0)]
```

Todo

Choose a good set of Cartan Type to run on. Rank >4 is too big. But C_1 and B_1 are boring.

We now check systematically that those operators satisfy the relations of the Iwahori-Hecke algebra:

```
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(affine=True, crystallographic=True): # long
....:     if cartan_type.rank() > 4: continue
....:     if cartan_type.type() == 'BC': continue
```

```
....:     KL = RootSystem(cartan_type).weight_lattice().algebra(K)
....:     T = KL.twisted_demazure_lusztig_operators(q1, q2, convention="dominant")
....:     T._test_relations()
```

Todo

Investigate why $T_0^\vee$ currently does not satisfy the quadratic relation in type BC. This should hopefuly be fixed when $T_0^\vee$ will have a more uniform implementation:

```
sage: cartan_type = CartanType(["BC",1,2])
sage: KL = RootSystem(cartan_type).weight_lattice().algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")
sage: T._test_relations()
... tester.assert_(Ti(Ti(x,i,-q2),i,-q1).is_zero()) ...
AssertionError: False is not true
Traceback (most recent call last):
```

Comparison with T0:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['t,q'].fraction_field()
sage: t,q = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = L.algebra(K)
sage: L0 = L.classical()
sage: T = KL.demazure_lusztig_operators(q1,q2, convention="dominant")
sage: def T0(*l0): return KL.q_project(T[0].on_basis()(L.embed_at_level(L0(l0), 1)), q)
sage: T0_check_on_basis = KL.T0_check_on_basis(q1, q2, convention="dominant")
sage: def T0c(*l0): return T0_check_on_basis(L0(l0))

sage: T0(0,0,1)                                    # not double checked
((-t+1)/q)*B[(1, 0, 0)] + 1/q^2*B[(2, 0, -1)]
sage: T0c(0,0,1)
(t^2-t)*B[(1, 0, 0)] + (t^2-t)*B[(1, 1, -1)] + t^2*B[(2, 0, -1)] + (t-1)*B[(0, 0, 1)]
```

5.1.208 Root lattice realizations

class sage.combinat.root_system.root_lattice_realizations.**RootLatticeRealizations**(*base*, *name=None*)

Bases: sage.categories.category_types.Category_over_base_ring

The category of root lattice realizations over a given base ring

A *root lattice realization* L over a base ring R is a free module (or vector space if R is a field) endowed with an embedding of the root lattice of some root system.

Typical root lattice realizations over $\mathbf{Z}$ include the root lattice, weight lattice, and ambient lattice. Typical root lattice realizations over $\mathbf{Q}$ include the root space, weight space, and ambient space.

To describe the embedding, a root lattice realization must implement a method `simple_root()` returning for each i in the index set the image of the simple root α_i under the embedding.

A root lattice realization must further implement a method on elements `scalar()`, computing the scalar product with elements of the coroot lattice or coroot space.

Using those, this category provides tools for reflections, roots, the Weyl group and its action, ...

See also:

- RootSystem
- WeightLatticeRealizations
- RootSpace
- WeightSpace
- AmbientSpace

EXAMPLES:

Here, we consider the root system of type A_7, and embed the root lattice element $x = \alpha_2 + 2\alpha_6$ in several root lattice realizations:

```
sage: R = RootSystem(["A",7])
sage: alpha = R.root_lattice().simple_roots()
sage: x = alpha[2] + 2 * alpha[5]

sage: L = R.root_space()
sage: L(x)
alpha[2] + 2*alpha[5]

sage: L = R.weight_lattice()
sage: L(x)
-Lambda[1] + 2*Lambda[2] - Lambda[3] - 2*Lambda[4] + 4*Lambda[5] - 2*Lambda[6]

sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 2, -2, 0, 0)
```

We embed the root space element $x = \alpha_2 + 1/2\alpha_6$ in several root lattice realizations:

```
sage: alpha = R.root_space().simple_roots()
sage: x = alpha[2] + 1/2 * alpha[5]

sage: L = R.weight_space()
sage: L(x)
-Lambda[1] + 2*Lambda[2] - Lambda[3] - 1/2*Lambda[4] + Lambda[5] - 1/2*Lambda[6]

sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 1/2, -1/2, 0, 0)
```

Of course, one can't embed the root space in the weight lattice:

```
sage: L = R.weight_lattice()
sage: L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= alpha[2] + 1/2*alpha[5]) an element of self (=Weight lat
```

If K_1 is a subring of K_2, then one could in theory have an embedding from the root space over K_1 to any root lattice realization over K_2; this is not implemented:

```
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.weight_space(K2)

sage: alpha = R.root_space(K2).simple_roots()
sage: L(alpha[1])
2*Lambda[1] - Lambda[2]
```

```
sage: alpha = R.root_space(K1).simple_roots()
sage: L(alpha[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= alpha[1]) an element of self (=Weight space over the Uni
```

By a slight abuse, the embedding of the root lattice is not actually required to be faithful. Typically for an affine root system, the null root of the root lattice is killed in the non extended weight lattice:

```
sage: R = RootSystem(["A", 3, 1])
sage: delta = R.root_lattice().null_root()
sage: L = R.weight_lattice()
sage: L(delta)
0
```

TESTS:

```
sage: TestSuite(L).run()
```

Algebras
alias of Algebras

class ElementMethods

associated_coroot()
Returns the coroot associated to this root

EXAMPLES:

```
sage: alpha = RootSystem(["A", 3]).root_space().simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
```

associated_reflection()
Given a positive root `self`, returns a reduced word for the reflection orthogonal to `self`.

Since the answer is cached, it is a tuple instead of a list.

EXAMPLES:

```
sage: RootSystem(['C',3]).root_lattice().simple_root(3).weyl_action([1,2]).associated_re
(1, 2, 3, 2, 1)
sage: RootSystem(['C',3]).root_lattice().simple_root(2).associated_reflection()
(2,)
```

descents(*index_set=None*, *positive=False*)
Returns the descents of pt

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=space.simple_roots()
sage: (alpha[1]+alpha[2]+alpha[4]).descents()
[3, 5]
```

extraspecial_pair()
Return the extraspecial pair of `self` under the ordering defined by `positive_roots_by_height()`.

The *extraspecial pair* of a positive root γ with some total ordering $<$ of the root lattice that respects height is the pair of positive roots (α, β) such that $\gamma = \alpha + \beta$ and α is as small as possible.

EXAMPLES:

```
sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().extraspecial_pair()
(alpha[2], 3*alpha[1] + alpha[2])
```

first_descent(*index_set=None*, *positive=False*)

Returns the first descent of pt

One can use the index_set option to restrict to the parabolic subgroup indexed by index_set.

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=space.simple_roots()
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent()
3
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5])
5
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5,3,4])
5
```

greater()

Returns the elements in the orbit of self which are greater than self in the weak order.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].greater()
[(0, 0, 1, 0), (0, 0, 0, 1)]
sage: len(L.rho().greater())
24
sage: len((-L.rho()).greater())
1
sage: sorted([len(x.greater()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]
```

has_descent(*i*, *positive=False*)

Test if self has a descent at position i, that is if self is on the strict negative side of the i^{th} simple reflection hyperplane.

If positive if True, tests if it is on the strict positive side instead.

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: [alpha[i].has_descent(1) for i in space.index_set()]
[False, True, False, False, False]
sage: [(-alpha[i]).has_descent(1) for i in space.index_set()]
[True, False, False, False, False]
sage: [alpha[i].has_descent(1, True) for i in space.index_set()]
[True, False, False, False, False]
sage: [(-alpha[i]).has_descent(1, True) for i in space.index_set()]
[False, True, False, False, False]
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(3)
True
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1)
False
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1, True)
True
```

height()

Return the height of `self`.

The height of a root $\alpha = \sum_i a_i \alpha_i$ is defined to be $h(\alpha) := \sum_i a_i$.

EXAMPLES:

```
sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().height()
5
```

is_dominant (*index_set=None*, *positive=True*)

Returns whether self is dominant.

This is done with respect to the subrootsystem indicated by the subset of Dynkin nodes index_set. If index_set is None then the entire Dynkin node set is used. If positive is False then the dominance condition is replaced by antidominance.

EXAMPLES:

```
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: [x.is_dominant(positive=False) for x in Lambda]
[False, False]
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
sage: (Lambda[1]-Lambda[2]).is_dominant([1])
True
sage: (Lambda[1]-Lambda[2]).is_dominant([2])
False
sage: [x.is_dominant() for x in L.roots()]
[False, True, False, False, False, False]
sage: [x.is_dominant(positive=False) for x in L.roots()]
[False, False, False, False, True, False]
```

is_dominant_weight ()

Tests whether `self` is a dominant element of the weight lattice

EXAMPLES:

```
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: (3*Lambda[1]+Lambda[2]).is_dominant()
True
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
```

Tests that the scalar products with the coroots are all nonnegative integers. For example, if x is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports x to be a dominant weight:

```
sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True
```

is_imaginary_root ()

Return `True` if `self` is an imaginary root.

A root α is imaginary if it is not W conjugate to a simple root where W is the corresponding Weyl group.

EXAMPLES:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_imaginary_root()
False
sage: elt = alpha[0] + alpha[1] + 2*alpha[2]
sage: elt.is_imaginary_root()
True
```

is_long_root()

Return `True` if `self` is a long (real) root.

EXAMPLES:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_long_root()
True
sage: alpha[1].is_long_root()
True
sage: alpha[2].is_long_root()
False
```

is_parabolic_root(*index_set*)

Supposing that `self` is a root, is it in the parabolic subsystem with Dynkin nodes `index_set`?

INPUT:

- `index_set` – the Dynkin node set of the parabolic subsystem.

Todo

This implementation is only valid in the root or weight lattice

---

EXAMPLES:

```
sage: alpha = RootSystem(['A',3]).root_lattice().from_vector(vector([1,1,0]))
sage: alpha.is_parabolic_root([1,3])
False
sage: alpha.is_parabolic_root([1,2])
True
sage: alpha.is_parabolic_root([2])
False
```

is_real_root()

Return `True` if `self` is a real root.

A root α is real if it is W conjugate to a simple root where W is the corresponding Weyl group.

EXAMPLES:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_real_root()
True
sage: elt = alpha[0] + alpha[1] + 2*alpha[2]
sage: elt.is_real_root()
False
```

is_short_root()

Return `True` if `self` is a short (real) root.

Returns False unless the parent is an irreducible root system of finite type having two root lengths and `self` is of the shorter length. There is no check of whether `self` is actually a root.

EXAMPLES:

```
sage: Q = RootSystem(['C',2]).root_lattice()
sage: al = Q.simple_root(1).weyl_action([1,2]); al
alpha[1] + alpha[2]
sage: al.is_short_root()
True
sage: bt = Q.simple_root(2).weyl_action([2,1,2]); bt
-2*alpha[1] - alpha[2]
sage: bt.is_short_root()
False
sage: RootSystem(['A',2]).root_lattice().simple_root(1).is_short_root()
False
```

An example in affine type:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_short_root()
False
sage: alpha[1].is_short_root()
False
sage: alpha[2].is_short_root()
True
```

level()

EXAMPLES:

```
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.rho().level()
3
```

norm_squared()

Return the norm squared of `self` with respect to the symmetric form.

EXAMPLES:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].norm_squared()
4
sage: alpha[2].norm_squared()
2
sage: elt = alpha[0] - 3*alpha[1] + alpha[2]
sage: elt.norm_squared()
50
sage: elt = alpha[0] + alpha[1] + 2*alpha[2]
sage: elt.norm_squared()
0
sage: Q = RootSystem(CartanType(['A',4,2]).dual()).root_lattice()
sage: Qc = RootSystem(['A',4,2]).coroot_lattice()
sage: alpha = Q.simple_roots()
sage: alphac = Qc.simple_roots()
sage: elt = alpha[0] + 2*alpha[1] + 2*alpha[2]
sage: eltc = alphac[0] + 2*alphac[1] + 2*alphac[2]
sage: elt.norm_squared()
0
sage: eltc.norm_squared()
0
```

orbit()

The orbit of self under the action of the Weyl group

EXAMPLES:

ρ is a regular element whose orbit is in bijection with the Weyl group. In particular, it as 6 elements for the symmetric group S_3:

```
sage: L = RootSystem(["A", 2]).ambient_lattice()
sage: sorted(L.rho().orbit())                # the output order is not specified
[(1, 2, 0), (1, 0, 2), (2, 1, 0), (2, 0, 1), (0, 1, 2), (0, 2, 1)]

sage: L = RootSystem(["A", 3]).weight_lattice()
sage: len(L.rho().orbit())
24
sage: len(L.fundamental_weights()[1].orbit())
4
sage: len(L.fundamental_weights()[2].orbit())
6
```

pred(*index_set=None*)

Return the immediate predecessors of `self` for the weak order.

INPUT:

- `index_set` - a subset (as a list or iterable) of the nodes of the dynkin diagram; (default: `None` for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].pred()
[]
sage: L.rho().pred()
[]
sage: (-L.rho()).pred()
[Lambda[1] - 2*Lambda[2] - Lambda[3], -2*Lambda[1] + Lambda[2] - 2*Lambda[3], -Lambda[1]
sage: (-L.rho()).pred(index_set=[1])
[Lambda[1] - 2*Lambda[2] - Lambda[3]]
```

reduced_word(*index_set=None*, *positive=True*)

Returns a reduced word for the inverse of the shortest Weyl group element that sends the vector `self` into the dominant chamber.

With the `index_set` optional parameter, this is done with respect to the corresponding parabolic subgroup.

If `positive` is False, use the antidominant chamber instead.

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].reduced_word()
[2, 3, 4, 5]
sage: alpha[1].reduced_word([1,2])
[2]
```

reflection(*root*, *use_coroot=False*)

Reflects `self` across the hyperplane orthogonal to `root`.

If `use_coroot` is True, `root` is interpreted as a coroot.

EXAMPLES:

```
sage: R = RootSystem(['C',4])
sage: weight_lattice = R.weight_lattice()
sage: mu = weight_lattice.from_vector(vector([0,0,1,2]))
sage: coroot_lattice = R.coroot_lattice()
sage: alphavee = coroot_lattice.from_vector(vector([0,0,1,1]))
sage: mu.reflection(alphavee, use_coroot=True)
6*Lambda[2] - 5*Lambda[3] + 2*Lambda[4]
sage: root_lattice = R.root_lattice()
sage: beta = root_lattice.from_vector(vector([0,1,1,0]))
sage: mu.reflection(beta)
Lambda[1] - Lambda[2] + 3*Lambda[4]
```

scalar(*lambdacheck*)

Implement the natural pairing with the coroot lattice.

INPUT:

- `self` – an element of a root lattice realization
- `lambdacheck` – an element of the coroot lattice or coroot space

OUTPUT: the scalar product of `self` and `lambdacheck`

EXAMPLES:

```
sage: L = RootSystem(['A',4]).root_lattice()
sage: alpha      = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
sage: matrix([ [ alpha[i].scalar(alphacheck[j])
...              for i in L.index_set() ]
...            for j in L.index_set() ])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
```

TESTS:

```
sage: super(sage.combinat.root_system.root_space.RootSpaceElement,alpha[1]).scalar(alpha
Traceback (most recent call last):
...
NotImplementedError: <abstract method scalar at ...>
```

simple_reflection(*i*)

Returns the image of `self` by the i-th simple reflection.

EXAMPLES:

```
sage: alpha = RootSystem(["A", 3]).root_lattice().alpha()
sage: alpha[1].simple_reflection(2)
alpha[1] + alpha[2]

sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True)
sage: Lambda = Q.fundamental_weights()
sage: L = Lambda[0] + Q.null_root()
sage: L.simple_reflection(0)
-Lambda[0] + Lambda[1] + Lambda[3]
```

simple_reflections()

The images of self by all the simple reflections

EXAMPLES:

```
sage: alpha = RootSystem(["A", 3]).root_lattice().alpha()
sage: alpha[1].simple_reflections()
[-alpha[1], alpha[1] + alpha[2], alpha[1]]
```

smaller()

Returns the elements in the orbit of self which are smaller than self in the weak order.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].smaller()
[(0, 0, 1, 0), (0, 1, 0, 0), (1, 0, 0, 0)]
sage: len(L.rho().smaller())
1
sage: len((-L.rho()).smaller())
24
sage: sorted([len(x.smaller()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]
```

succ(*index_set=None*)

Return the immediate successors of `self` for the weak order.

INPUT:

- `index_set` - a subset (as a list or iterable) of the nodes of the dynkin diagram; (default: `None` for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].succ()
[-Lambda[1] + Lambda[2]]
sage: L.rho().succ()
[-Lambda[1] + 2*Lambda[2] + Lambda[3], 2*Lambda[1] - Lambda[2] + 2*Lambda[3], Lambda[1] +
sage: (-L.rho()).succ()
[]
sage: L.rho().succ(index_set=[1])
[-Lambda[1] + 2*Lambda[2] + Lambda[3]]
sage: L.rho().succ(index_set=[2])
[2*Lambda[1] - Lambda[2] + 2*Lambda[3]]
```

symmetric_form(*alpha*)

Return the symmetric form of `self` with `alpha`.

Consider the simple roots α_i and let $(b_{ij})_{ij}$ denote the symmetrized Cartan matrix $(a_{ij})_{ij}$, we have

$$(\alpha_i|\alpha_j) = b_{ij}$$

and extended bilinearly. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

EXAMPLES:

```
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].symmetric_form(alpha[0])
0
sage: alpha[1].symmetric_form(alpha[1])
4
sage: elt = alpha[0] - 3*alpha[1] + alpha[2]
sage: elt.symmetric_form(alpha[1])
```

```
-14
sage: elt.symmetric_form(alpha[0]+2*alpha[2])
14
sage: Q = RootSystem(CartanType(['A',4,2]).dual()).root_lattice()
sage: Qc = RootSystem(['A',4,2]).coroot_lattice()
sage: alpha = Q.simple_roots()
sage: alphac = Qc.simple_roots()
sage: elt = alpha[0] + 2*alpha[1] + 2*alpha[2]
sage: eltc = alphac[0] + 2*alphac[1] + 2*alphac[2]
sage: elt.symmetric_form(alpha[1])
0
sage: eltc.symmetric_form(alphac[1])
0
```

to_ambient()

Map `self` to the ambient space.

EXAMPLES:

```
sage: alpha = CartanType(['B',4]).root_system().root_lattice().an_element(); alpha
2*alpha[1] + 2*alpha[2] + 3*alpha[3]
sage: alpha.to_ambient()
(2, 0, 1, -3)
sage: mu = CartanType(['B',4]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2] + 3*Lambda[3]
sage: mu.to_ambient()
(7, 5, 3, 0)
sage: v = CartanType(['B',4]).root_system().ambient_space().an_element(); v
(2, 2, 3, 0)
sage: v.to_ambient()
(2, 2, 3, 0)
sage: alphavee = CartanType(['B',4]).root_system().coroot_lattice().an_element(); alphav
2*alphacheck[1] + 2*alphacheck[2] + 3*alphacheck[3]
sage: alphavee.to_ambient()
(2, 0, 1, -3)
```

to_classical()

Map `self` to the classical lattice/space.

Only makes sense for affine type.

EXAMPLES:

```
sage: R = CartanType(['A',3,1]).root_system()
sage: alpha = R.root_lattice().an_element(); alpha
2*alpha[0] + 2*alpha[1] + 3*alpha[2]
sage: alb = alpha.to_classical(); alb
alpha[2] - 2*alpha[3]
sage: alb.parent()
Root lattice of the Root system of type ['A', 3]
sage: v = R.ambient_space().an_element(); v
2*e[0] + 2*e[1] + 3*e[2]
sage: v.to_classical()
(2, 2, 3, 0)
```

to_dominant_chamber(*index_set=None*, *positive=True*, *reduced_word=False*)

Returns the unique dominant element in the Weyl group orbit of the vector `self`.

If `positive` is False, returns the antidominant orbit element.

With the `index_set` optional parameter, this is done with respect to the corresponding parabolic subgroup.

If `reduced_word` is True, returns the 2-tuple (`weight`, `direction`) where `weight` is the (anti)dominant orbit element and `direction` is a reduced word for the Weyl group element sending `weight` to `self`.

Warning: In infinite type, an orbit may not contain a dominant element. In this case the function may go into an infinite loop.
For affine root systems, errors are generated if the orbit does not contain the requested kind of representative. If the input vector is of positive (resp. negative) level, then there is a dominant (resp. antidominant) element in its orbit but not an antidominant (resp. dominant) one. If the vector is of level zero, then there are neither dominant nor antidominant orbit representatives, except for multiples of the null root, which are themselves both dominant and antidominant orbit representatives.

EXAMPLES:

```
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha=RootSystem(['A',5]).weight_space().simple_roots()
sage: alpha[1].to_dominant_chamber()
Lambda[1] + Lambda[5]
sage: alpha[1].to_dominant_chamber([1,2])
Lambda[1] + Lambda[2] - Lambda[3]
sage: wl=RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: mu=wl.from_vector(vector([1,-3,0]))
sage: mu.to_dominant_chamber(positive=False, reduced_word = True)
(-Lambda[1] - Lambda[2] - delta, [0, 2])

sage: R = RootSystem(['A',1,1])
sage: rl = R.root_lattice()
sage: nu = rl.zero()
sage: nu.to_dominant_chamber()
0
sage: nu.to_dominant_chamber(positive=False)
0
sage: mu = rl.from_vector(vector([0,1]))
sage: mu.to_dominant_chamber()
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the fundamental chamber
sage: mu.to_dominant_chamber(positive=False)
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the negative of the fundamental chamber
```

to_dual_type_cospace()
Map `self` to the dual type cospace.

For example, if `self` is in the root lattice of type $['B', 2]$, send it to the coroot lattice of type $['C', 2]$.

EXAMPLES:

```
sage: v = CartanType(['C',3]).root_system().weight_lattice().an_element(); v
2*Lambda[1] + 2*Lambda[2] + 3*Lambda[3]
sage: w = v.to_dual_type_cospace(); w
2*Lambdacheck[1] + 2*Lambdacheck[2] + 3*Lambdacheck[3]
sage: w.parent()
Coweight lattice of the Root system of type ['B', 3]
```

to_simple_root(*reduced_word=False*)
Return (the index of) a simple root in the orbit of the positive root `self`.

INPUT:

- self – a positive root
- reduced_word – a boolean (default: False)

OUTPUT:

- The index i of a simple root α_i. If reduced_word is True, this returns instead a pair (i, word), where word is a sequence of reflections mapping α_i up the root poset to self.

EXAMPLES:

```
sage: L = RootSystem(["A",3]).root_lattice()
sage: positive_roots = L.positive_roots()
sage: for alpha in positive_roots:
...       print alpha, alpha.to_simple_root()
alpha[1] 1
alpha[2] 2
alpha[3] 3
alpha[1] + alpha[2] 2
alpha[2] + alpha[3] 3
alpha[1] + alpha[2] + alpha[3] 3
sage: for alpha in positive_roots:
...       print alpha, alpha.to_simple_root(reduced_word=True)
alpha[1] (1, ())
alpha[2] (2, ())
alpha[3] (3, ())
alpha[1] + alpha[2] (2, (1,))
alpha[2] + alpha[3] (3, (2,))
alpha[1] + alpha[2] + alpha[3] (3, (1, 2))
```

ALGORITHM:

This method walks from self down to the antidominant chamber by applying successively the simple reflection given by the first descent. Since self is a positive root, each step goes down the root poset, and one must eventually cross a simple root α_i.

See also:

- first_descent()
- to_dominant_chamber()

Warning: The behavior is not specified if the input is not a positive root. For a finite root system, this is currently caught (albeit with a not perfect message):

```
sage: alpha = L.simple_roots()
sage: (2*alpha[1]).to_simple_root()
Traceback (most recent call last):
...
ValueError: -2*alpha[1] - 2*alpha[2] - 2*alpha[3] is not a positive root
```

For an infinite root systems, this method may run into an infinite reccursion if the input is not a positive root.

translation(x)

INPUT:

- self - an element t at level 0
- x - an element of the same space

Returns x translated by t, that is $x + level(x)t$

EXAMPLES:

```
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = L.simple_roots()
sage: Lambda = L.fundamental_weights()
sage: t = alpha[2]
```

Let us look at the translation of an element of level 1:

```
sage: Lambda[1].level()
1
sage: t.translation(Lambda[1])
-Lambda[0] + 2*Lambda[2]
sage: Lambda[1] + t
-Lambda[0] + 2*Lambda[2]
```

and of an element of level 0:

```
sage: alpha [1].level()
0
sage: t.translation(alpha [1])
-Lambda[0] + 2*Lambda[1] - Lambda[2]
sage: alpha[1] + 0*t
-Lambda[0] + 2*Lambda[1] - Lambda[2]
```

The arguments are given in this seemingly unnatural order to make it easy to construct the translation function:

```
sage: f = t.translation
sage: f(Lambda[1])
-Lambda[0] + 2*Lambda[2]
```

weyl_action(*element*, *inverse=False*)

Acts on `self` by an element of the Coxeter or Weyl group.

INPUT:

- `element` – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set.
- `inverse` – a boolean (default: False); whether to act by the inverse element.

EXAMPLES:

```
sage: wl = RootSystem(['A',3]).weight_lattice()
sage: mu = wl.from_vector(vector([1,0,-2]))
sage: mu
Lambda[1] - 2*Lambda[3]
sage: mudom, rw = mu.to_dominant_chamber(positive=False, reduced_word = True)
sage: mudom, rw
(-Lambda[2] - Lambda[3], [1, 2])
```

Acting by a (reduced) word:

```
sage: mudom.weyl_action(rw)
Lambda[1] - 2*Lambda[3]
sage: mu.weyl_action(rw, inverse = True)
-Lambda[2] - Lambda[3]
```

Acting by an element of the Coxeter or Weyl group on a vector in its own lattice of definition (implemented by matrix multiplication on a vector):

```
sage: w = wl.weyl_group().from_reduced_word([1, 2])
sage: mudom.weyl_action(w)
Lambda[1] - 2*Lambda[3]
```

Acting by an element of an isomorphic Coxeter or Weyl group (implemented by the action of a corresponding reduced word):

```
sage: W = WeylGroup(['A',3], prefix="s")
sage: w = W.from_reduced_word([1, 2])
sage: wl.weyl_group() == W
False
sage: mudom.weyl_action(w)
Lambda[1] - 2*Lambda[3]
```

weyl_stabilizer(*index_set=None*)

Returns the subset of Dynkin nodes whose reflections fix `self`.

If `index_set` is not None, only consider nodes in this set. Note that if `self` is dominant or antidominant, then its stabilizer is the parabolic subgroup defined by the returned node set.

EXAMPLES:

```
sage: wl = RootSystem(['A',2,1]).weight_lattice(extended = True)
sage: al = wl.null_root()
sage: al.weyl_stabilizer()
[0, 1, 2]
sage: wl = RootSystem(['A',4]).weight_lattice()
sage: mu = wl.from_vector(vector([1,1,0,0]))
sage: mu.weyl_stabilizer()
[3, 4]
sage: mu.weyl_stabilizer(index_set = [1,2,3])
[3]
```

class RootLatticeRealizations.**ParentMethods**

a_long_simple_root()

Returns a long simple root, corresponding to the highest outgoing edge in the Dynkin diagram.

Caveat: this may be break in affine type $A_{2n}^{(2)}$

Caveat: meaningful/broken for non irreducible?

TODO: implement CartanType.nodes_by_length as in MuPAD-Combinat (using CartanType.symmetrizer), and use it here.

TESTS:

```
sage: X=RootSystem(['A',1]).weight_space()
sage: X.a_long_simple_root()
2*Lambda[1]
sage: X=RootSystem(['A',5]).weight_space()
sage: X.a_long_simple_root()
2*Lambda[1] - Lambda[2]
```

almost_positive_roots()

Returns the almost positive roots of `self`

These are the positive roots together with the simple negative roots.

See also:

`almost_positive_root_decomposition()`, `tau_plus_minus()`

EXAMPLES:

```
sage: L = RootSystem(['A',2]).root_lattice()
sage: L.almost_positive_roots()
[-alpha[1], alpha[1], alpha[1] + alpha[2], -alpha[2], alpha[2]]
```

almost_positive_roots_decomposition()
Returns the decomposition of the almost positive roots of `self`

This is the list of the orbits of the almost positive roots under the action of the dihedral group generated by the operators τ_+ and τ_-.

See also:

- almost_positive_roots()
- tau_plus_minus()

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().almost_positive_roots_decomposition()
[[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2], -alpha[2]]]

sage: RootSystem(['B',2]).root_lattice().almost_positive_roots_decomposition()
[[-alpha[1], alpha[1], alpha[1] + 2*alpha[2]], [-alpha[2], alpha[2], alpha[1] + alpha[2]

sage: RootSystem(['D',4]).root_lattice().almost_positive_roots_decomposition()
[[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2] + alpha[3] + alpha[4]],
 [-alpha[2], alpha[2], alpha[1] + alpha[2] + alpha[3] + alpha[4], alpha[1] + 2*alpha[2]
 [-alpha[3], alpha[3], alpha[2] + alpha[3], alpha[1] + alpha[2] + alpha[4]],
 [-alpha[4], alpha[4], alpha[2] + alpha[4], alpha[1] + alpha[2] + alpha[3]]]
```

alpha()
Returns the family $(\alpha_i)_{i\in I}$ of the simple roots, with the extra feature that, for simple irreducible root systems, α_0 yields the opposite of the highest root.

EXAMPLES:

```
sage: alpha = RootSystem(["A",2]).root_lattice().alpha()
sage: alpha[1]
alpha[1]
sage: alpha[0]
-alpha[1] - alpha[2]
```

alphacheck()
Returns the family $(\alpha_i^\vee)_{i\in I}$ of the simple coroots, with the extra feature that, for simple irreducible root systems, $\alpha_0^\vee$ yields the coroot associated to the opposite of the highest root (caveat: for non simply laced root systems, this is not the opposite of the highest coroot!)

EXAMPLES:

```
sage: alphacheck = RootSystem(["A",2]).ambient_space().alphacheck()
sage: alphacheck
Finite family {1: (1, -1, 0), 2: (0, 1, -1)}
```

Here is now $\alpha_0^\vee$:
(-1, 0, 1)

Todo

add a non simply laced example

Finaly, here is an affine example:

```
sage: RootSystem(["A",2,1]).weight_space().alphacheck()
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}

sage: RootSystem(["A",3]).ambient_space().alphacheck()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

basic_imaginary_roots()
Return the basic imaginary roots of `self`.

The basic imaginary roots δ are the set of imaginary roots in $-C^\vee$ where C is the dominant chamger (i.e., $\langle \beta, \alpha_i^\vee \rangle \leq 0$ for all $i \in I$). All imaginary roots are W-conjugate to a simple imaginary root.

EXAMPLES:

```
sage: RootSystem(['A', 2]).root_lattice().basic_imaginary_roots()
()
sage: Q = RootSystem(['A', 2, 1]).root_lattice()
sage: Q.basic_imaginary_roots()
(alpha[0] + alpha[1] + alpha[2],)
sage: delta = Q.basic_imaginary_roots()[0]
sage: all(delta.scalar(Q.simple_coroot(i)) <= 0 for i in Q.index_set())
True
```

cartan_type()
EXAMPLES:

```
sage: r = RootSystem(['A',4]).root_space()
sage: r.cartan_type()
['A', 4]
```

classical()
Return the corresponding root/weight/ambient lattice/space.

EXAMPLES:

```
sage: RootSystem(["A",4,1]).root_lattice().classical()
Root lattice of the Root system of type ['A', 4]
sage: RootSystem(["A",4,1]).weight_lattice().classical()
Weight lattice of the Root system of type ['A', 4]
sage: RootSystem(["A",4,1]).ambient_space().classical()
Ambient space of the Root system of type ['A', 4]
```

cohighest_root()
Returns the associated coroot of the highest root.

Note: this is usually not the highest coroot.

EXAMPLES:

```
sage: RootSystem(['A', 3]).ambient_space().cohighest_root()
(1, 0, 0, -1)
```

coroot_lattice()
Returns the coroot lattice.

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().coroot_lattice()
Coroot lattice of the Root system of type ['A', 2]
```

coroot_space(*base_ring=Rational Field*)
Returns the coroot space over `base_ring`

INPUT:

- `base_ring` – a ring (default: **Q**)

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 2]
```

```
sage: RootSystem(['A',2]).root_lattice().coroot_space(QQ['q'])
Coroot space over the Univariate Polynomial Ring in q over Rational Field of the Root sy
```

dual_type_cospace()

Returns the cospace of dual type.

For example, if invoked on the root lattice of type $['B', 2]$, returns the coroot lattice of type $['C', 2]$.

..warning:
Not implemented for ambient spaces.

EXAMPLES:

```
sage: CartanType(['B',2]).root_system().root_lattice().dual_type_cospace()
Coroot lattice of the Root system of type ['C', 2]
sage: CartanType(['F',4]).root_system().coweight_lattice().dual_type_cospace()
Weight lattice of the Root system of type ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1
```

dynkin_diagram()

EXAMPLES:

```
sage: r = RootSystem(['A',4]).root_space()
sage: r.dynkin_diagram()
O---O---O---O
1   2   3   4
A4
```

fundamental_weights_from_simple_roots()

Return the fundamental weights.

This is computed from the simple roots by using the inverse of the Cartan matrix. This method is therefore only valid for finite types and if this realization of the root lattice is large enough to contain them.

EXAMPLES:

In the root space, we retrieve the inverse of the Cartan matrix:

```
sage: L = RootSystem(["B",3]).root_space()
sage: L.fundamental_weights_from_simple_roots()
Finite family {1:     alpha[1] +   alpha[2] +     alpha[3],
               2:     alpha[1] + 2*alpha[2] +   2*alpha[3],
               3: 1/2*alpha[1] +   alpha[2] + 3/2*alpha[3]}
sage: ~L.cartan_type().cartan_matrix()
[  1   1 1/2]
[  1   2   1]
[  1   2 3/2]
```

In the weight lattice and the ambient space, we retrieve the fundamental weights:

```
sage: L = RootSystem(["B",3]).weight_lattice()
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}

sage: L = RootSystem(["B",3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

However the fundamental weights do not belong to the root lattice:

```
sage: L = RootSystem(["B",3]).root_lattice()
sage: L.fundamental_weights_from_simple_roots()
```

```
Traceback (most recent call last):
...
ValueError: The fundamental weights do not live in this realization of the root lattice
```

Beware of the usual GL_n vs SL_n catch in type A:

```
sage: L = RootSystem(["A",3]).ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: L.fundamental_weights_from_simple_roots()
Finite family {1: (3/4, -1/4, -1/4, -1/4), 2: (1/2, 1/2, -1/2, -1/2), 3: (1/4, 1/4, 1/4,

sage: L = RootSystem(["A",3]).ambient_lattice()
sage: L.fundamental_weights_from_simple_roots()
Traceback (most recent call last):
...
ValueError: The fundamental weights do not live in this realization of the root lattice
```

generalized_nonnesting_partition_lattice(*m*, *facade=False*)

Return the lattice of m-nonnesting partitions

This has been defined by Athanasiadis, see chapter 5 of [Arm06].

INPUT:

- m – integer

See also:

`nonnesting_partition_lattice()`

EXAMPLES:

```
sage: R = RootSystem(['A', 2])
sage: RS = R.root_lattice()
sage: P = RS.generalized_nonnesting_partition_lattice(2); P
Finite lattice containing 12 elements
sage: P.coxeter_transformation()**20 == 1
True
```

highest_root()

Returns the highest root (for an irreducible finite root system)

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_space().highest_root()
(1, 0, 0, 0, -1)

sage: RootSystem(['E',6]).weight_space().highest_root()
Lambda[2]
```

index_set()

EXAMPLES:

```
sage: r = RootSystem(['A',4]).root_space()
sage: r.index_set()
(1, 2, 3, 4)
```

long_roots()

Return a list of the long roots of `self`.

EXAMPLES:

```
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.long_roots())
[-alpha[1], -alpha[1] - 2*alpha[2] - 2*alpha[3],
```

```
 -alpha[1] - alpha[2], -alpha[1] - alpha[2] - 2*alpha[3],
 alpha[1], alpha[1] + alpha[2],
 alpha[1] + alpha[2] + 2*alpha[3],
 alpha[1] + 2*alpha[2] + 2*alpha[3], -alpha[2],
 -alpha[2] - 2*alpha[3], alpha[2], alpha[2] + 2*alpha[3]]
```

negative_roots()

Returns the negative roots of self.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).weight_lattice()
sage: sorted(L.negative_roots())
[-2*Lambda[1] + Lambda[2], -Lambda[1] - Lambda[2], Lambda[1] - 2*Lambda[2]]
```

Algorithm: negate the positive roots

nonnesting_partition_lattice(*facade=False*)

Return the lattice of nonnesting partitions

This is the lattice of order ideals of the root poset.

This has been defined by Postnikov, see Remark 2 in [Reiner97].

See also:

`generalized_nonnesting_partition_lattice()`, `root_poset()`

EXAMPLES:

```
sage: R = RootSystem(['A', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 14 elements
sage: P.coxeter_transformation()**10 == 1
True

sage: R = RootSystem(['B', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 20 elements
sage: P.coxeter_transformation()**7 == 1
True
```

REFERENCES:

nonparabolic_positive_root_sum(*index_set=None*)

Return the sum of positive roots not in a parabolic subsystem.

The conventions for `index_set` are as in `nonparabolic_positive_roots()`.

EXAMPLES:

```
sage: Q = RootSystem(['A',3]).root_lattice()
sage: Q.nonparabolic_positive_root_sum((1,2))
alpha[1] + 2*alpha[2] + 3*alpha[3]
sage: Q.nonparabolic_positive_root_sum()
0
sage: Q.nonparabolic_positive_root_sum(())
3*alpha[1] + 4*alpha[2] + 3*alpha[3]
```

nonparabolic_positive_roots(*index_set=None*)

Return the positive roots of `self` that are not in the parabolic subsystem indicated by `index_set`.

If index_set is None, as in positive_roots() it is assumed to be the entire Dynkin node set. Then the parabolic subsystem consists of all positive roots and the empty list is returned.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: L.nonparabolic_positive_roots()
[]
sage: sorted(L.nonparabolic_positive_roots((1,2)))
[alpha[1] + alpha[2] + alpha[3], alpha[2] + alpha[3], alpha[3]]
sage: sorted(L.nonparabolic_positive_roots(()))
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3], alpha[2], alpha[2] + alpl
```

null_coroot()

Returns the null coroot of self.

The null coroot is the smallest non trivial positive coroot which is orthogonal to all simple roots. It exists for any affine root system.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).root_lattice().null_coroot()
alphacheck[0] + alphacheck[1] + alphacheck[2]
sage: RootSystem(['D',4,1]).root_lattice().null_coroot()
alphacheck[0] + alphacheck[1] + 2*alphacheck[2] + alphacheck[3] + alphacheck[4]
sage: RootSystem(['F',4,1]).root_lattice().null_coroot()
alphacheck[0] + 2*alphacheck[1] + 3*alphacheck[2] + 2*alphacheck[3] + alphacheck[4]
```

null_root()

Returns the null root of self. The null root is the smallest non trivial positive root which is orthogonal to all simple coroots. It exists for any affine root system.

EXAMPLES:

```
sage: RootSystem(['C',2,1]).root_lattice().null_root()
alpha[0] + 2*alpha[1] + alpha[2]
sage: RootSystem(['D',4,1]).root_lattice().null_root()
alpha[0] + alpha[1] + 2*alpha[2] + alpha[3] + alpha[4]
sage: RootSystem(['F',4,1]).root_lattice().null_root()
alpha[0] + 2*alpha[1] + 3*alpha[2] + 4*alpha[3] + 2*alpha[4]
```

plot(*roots='simple'*, *coroots=False*, *reflection_hyperplanes='simple'*, *fundamental_weights=None*, *fundamental_chamber=None*, *alcoves=None*, *alcove_labels=False*, *alcove_walk=None*, ***options*)

Return a picture of this root lattice realization.

INPUT:

- roots – which roots to display, if any. Can be one of the following:
  - "simple" – The simple roots (the default)
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of roots
  - False
- coroots – which coroots to display, if any. Can be one of the following:
  - "simple" – The simple coroots (the default)
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of coroots
  - False
- fundamental_weights – a boolean or None (default: None) whether to display the fundamental weights. If None, the fundamental weights are drawn if available.

- `reflection_hyperplanes` – which reflection hyperplanes to display, if any. Can be one of the following:
  - `"simple"` – The simple roots
  - `"classical"` – Not yet implemented
  - `"all"` – Only works in the finite case
  - A list or tuple of roots
  - `False` (the default)
- `fundamental_chamber` – whether and how to draw the fundamental chamber. Can be one of the following:
  - A boolean – Set to `True` to draw the fundamental chamber
  - `"classical"` – Draw the classical fundamental chamber
  - `None` – (the default) The fundamental chamber is drawn except in the root lattice where this is not yet implemented. For affine types the classical fundamental chamber is drawn instead.
- `alcoves` – one of the following (default: `True`):
  - A boolean – Whether to display the alcoves
  - A list of alcoves – The alcoves to be drawn. Each alcove is specified by the coordinates of its center in the root lattice (affine type only). Otherwise the alcoves that intersect the bounding box are drawn.
- `alcove_labels` – one of the following (default: `False`):
  - A boolean – Whether to display the elements of the Weyl group indexing the alcoves. This currently requires to also set the `alcoves` option.
  - A number l – The label is drawn at level l (affine type only), which only makes sense if `affine` is `False`.
- `bounding_box` – a rational number or a list of pairs thereof (default: 3)

  Specifies a bounding box, in the coordinate system for this plot, in which to plot alcoves and other infinite objects. If the bounding box is a number a, then the bounding box is of the form $[-a, a]$ in all directions. Beware that there can be some border effects and the returned graphic is not necessarily strictly contained in the bounding box.
- `alcove_walk` – an alcove walk or `None` (default: `None`)

  The alcove walk is described by a list (or iterable) of vertices of the Dynkin diagram which specifies which wall is crossed at each step, starting from the fundamental alcove.
- `projection` – one of the following (default: `True`):
  - `True` – The default projection for the root lattice realization is used.
  - `False` – No projection is used.
  - `barycentric` – A barycentric projection is used.
  - A function – If a function is specified, it should implement a linear (or affine) map taking as input an element of this root lattice realization and returning its desired coordinates in the plot, as a vector with rational coordinates.
- `color` – a function mapping vertices of the Dynkin diagram to colors (default: `"black"` for 0, `"blue"` for 1, `"red"` for 2, `"green"` for 3)

  This is used to set the color for the simple roots, fundamental weights, reflection hyperplanes, alcove facets, etc. If the color is `None`, the object is not drawn.
- `labels` – a boolean (default: `True`) whether to display labels on the simple roots, fundamental weights, etc.

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space().plot()     # long time
```

See also:

- `plot_parse_options()`
- `plot_roots()`, `plot_coroots()`
- `plot_fundamental_weights()`
- `plot_fundamental_chamber()`

- plot_reflection_hyperplanes()
- plot_alcoves()
- plot_alcove_walk()
- plot_ls_paths()
- plot_crystal()

plot_alcove_walk(*word*, *start=None*, *foldings=None*, *color='orange'*, ***options*)

Plot an alcove walk.

INPUT:

- word – a list of elements of the index set
- foldings – a list of booleans or None (default: None)
- start – an element of this space (default: None for ρ)
- **options – plotting options

See also:

- plot() for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

An alcove walk of type $A_2^{(1)}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,1,2,0,2,0,1,2,0]
sage: p = L.plot_alcoves(bounding_box=5)           # long time (5s)
sage: p += L.plot_alcove_walk(w1)                  # long time
sage: p                                            # long time
Graphics object consisting of 375 graphics primitives
```

The same plot with another alcove walk:

```
sage: w2 = [2,1,2,0,2,0,2,1,2,0,1,2,1,2,1,0,1,2,0,2,0,1,2,0,2]
sage: p += L.plot_alcove_walk(w2, color="orange")  # long time
```

And another with some foldings:

```
sage: L.plot_alcoves(bounding_box=3) + \
....:   L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],
....:                      foldings = [False, False, True, False, False, False, True, Fa
....:                      color="green")            # long time (3s)
Graphics object consisting of 155 graphics primitives
```

TESTS:

```
sage: L = RootSystem(["A",2,1]).weight_space()
sage: p = L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],
...                          foldings = [False, False, True, False, False, False, True,
...                          color="green",
...                          start=L.rho())
sage: print p.description()
Line defined by 2 points: [(-1.0, 8.0), (-1.5, 9.0)]
Line defined by 2 points: [(1.0, 4.0), (1.5, 4.5)]
Line defined by 2 points: [(1.0, 7.0), (1.5, 6.0)]
Arrow from (-1.0,5.0) to (-2.0,7.0)
Arrow from (-1.0,8.0) to (1.0,7.0)
Arrow from (-1.5,9.0) to (-1.0,8.0)
Arrow from (-2.0,7.0) to (-1.0,8.0)
Arrow from (1.0,1.0) to (2.0,2.0)
Arrow from (1.0,4.0) to (-1.0,5.0)
Arrow from (1.0,7.0) to (2.0,8.0)
Arrow from (1.5,4.5) to (1.0,4.0)
```

```
Arrow from (1.5,6.0) to (1.0,7.0)
Arrow from (2.0,2.0) to (1.0,4.0)
```

plot_alcoves(*alcoves=True*, *alcove_labels=False*, *wireframe=False*, ***options*)

Plot the alcoves and optionaly their labels.

INPUT:

- `alcoves` – a list of alcoves or `True` (default: `True`)
- `alcove_labels` – a boolean or a number specifying at which level to put the label (default: `False`)
- `**options` – Plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting, and in particular how the alcoves can be specified.

EXAMPLES:

2D plots:

```
sage: RootSystem(["B",2,1]).ambient_space().plot_alcoves()                    # long t
Graphics object consisting of 228 graphics primitives
```

3D plots:

```
sage: RootSystem(["A",2,1]).weight_space() .plot_alcoves(affine=False)        # long t
Graphics3d Object
sage: RootSystem(["G",2,1]).ambient_space().plot_alcoves(affine=False, level=1) # long t
Graphics3d Object
```

Here we plot a single alcove:

```
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: W = L.weyl_group()
sage: L.plot(alcoves=[W.one()], reflection_hyperplanes=False, bounding_box=2)
Graphics3d Object
```

TESTS:

```
sage: L = RootSystem(["A",2,1]).weight_space()
sage: p = L.plot_alcoves(alcoves=[[0,0]])
sage: print p.description()
Line defined by 2 points: [(-1.0, 0.0), (0.0, -1.0)]
Line defined by 2 points: [(-1.0, 1.0), (-1.0, 0.0)]
Line defined by 2 points: [(-1.0, 1.0), (0.0, 0.0)]
Line defined by 2 points: [(0.0, 0.0), (-1.0, 0.0)]
Line defined by 2 points: [(0.0, 0.0), (0.0, -1.0)]
Line defined by 2 points: [(0.0, 0.0), (1.0, -1.0)]
Line defined by 2 points: [(0.0, 1.0), (-1.0, 1.0)]
Line defined by 2 points: [(0.0, 1.0), (0.0, 0.0)]
Line defined by 2 points: [(0.0, 1.0), (1.0, 0.0)]
Line defined by 2 points: [(1.0, -1.0), (0.0, -1.0)]
Line defined by 2 points: [(1.0, 0.0), (0.0, 0.0)]
Line defined by 2 points: [(1.0, 0.0), (1.0, -1.0)]
sage: sorted((line.options()['rgbcolor'], line.options()['thickness']) for line in p)
[('black', 2), ('black', 2), ('black', 2),
 ('black', 2), ('black', 2), ('black', 2),
 ('blue', 1), ('blue', 1), ('blue', 1),
 ('red', 1), ('red', 1), ('red', 1)]
```

plot_bounding_box(***options*)

Plot the bounding box.

INPUT:

- `**options` – Plotting options

This is mostly for testing purposes.

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot_bounding_box()
Graphics object consisting of 1 graphics primitive
```

TESTS:

```
sage: list(L.plot_bounding_box())
[Polygon defined by 4 points]
```

plot_coroots(*collection='simple'*, ***options*)

Plot the (simple/classical) coroots of this root lattice.

INPUT:

- `collection` – which coroots to display. Can be one of the following:
  - `"simple"` (the default)
  - `"classical"`
  - `"all"`
- `**options` – Plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["B",3]).ambient_space().plot_coroots()
Graphics3d Object
```

TESTS:

```
sage: list(RootSystem(["B",2]).ambient_space().plot_coroots())
[Arrow from (0.0,0.0) to (1.0,-1.0),
 Text '$\alpha^\vee_{1}$' at the point (1.05,-1.05),
 Arrow from (0.0,0.0) to (0.0,2.0),
 Text '$\alpha^\vee_{2}$' at the point (0.0,2.1)]
```

plot_crystal(*crystal*, *plot_labels=True*, *label_color='black'*, *edge_labels=False*, *circle_size=0.06*, *circle_thickness=1.6*, ***options*)

Plot a finite crystal.

INPUT:

- `crystal` – the finite crystal to plot
- `plot_labels` – (default: `True`) can be one of the following:
  - `True` - use the latex labels
  - `'circles'` - use circles for multiplicity up to 4; if the multiplicity is larger, then it uses the multiplicity
  - `'multiplicities'` - use the multiplicities
- `label_color` – (default: `'black'`) the color of the labels
- `edge_labels` – (default: `False`) if `True`, then draw in the edge label
- `circle_size` – (default: 0.06) the size of the circles
- `circle_thickness` – (default: 1.6) the thinkness of the extra rings of circles
- `**options` – plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: L.plot_crystal(C)
Graphics object consisting of 16 graphics primitives
sage: C = crystals.Tableaux(['A',2], shape=[8,4])
sage: p = L.plot_crystal(C, plot_labels='circles')
sage: p.show(figsize=15)
```

A 3-dimensional example:

```
sage: L = RootSystem(['B',3]).ambient_space()
sage: C = crystals.Tableaux(['B',3], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='circles', edge_labels=True) # long time
Graphics3d Object
```

plot_fundamental_chamber(*style='normal'*, ***options*)

Plot the (classical) fundamental chamber.

INPUT:

- `style` – `"normal"` or `"classical"` (default: `"normal"`)
- `**options` – Plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

2D plots:

```
sage: RootSystem(["B",2]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(["B",2,1]).ambient_space().plot_fundamental_chamber()
Graphics object consisting of 1 graphics primitive
sage: RootSystem(["B",2,1]).ambient_space().plot_fundamental_chamber("classical")
Graphics object consisting of 1 graphics primitive
```

3D plots:

```
sage: RootSystem(["A",3,1]).weight_space() .plot_fundamental_chamber()
Graphics3d Object
sage: RootSystem(["B",3,1]).ambient_space().plot_fundamental_chamber()
Graphics3d Object
```

This feature is currently not available in the root lattice/space:

```
sage: list(RootSystem(["A",2]).root_lattice().plot_fundamental_chamber())
Traceback (most recent call last):
...
TypeError: classical fundamental chamber not yet available in the root lattice
```

TESTS:

```
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: print L.plot_fundamental_chamber().description()
Polygon defined by 3 points:     [(0.5, 0.5), (1.0, 0.0), (0.0, 0.0)]
```

```
sage: print L.plot_fundamental_chamber(style="classical").description()
Polygon defined by 3 points:     [(0.0, 0.0), (3.0, 3.0), (3.0, 0.0)]
```

plot_fundamental_weights(**options*)

Plot the fundamental weights of this root lattice.

INPUT:

- `**options` – Plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["B",3]).ambient_space().plot_fundamental_weights()
Graphics3d Object
```

TESTS:

```
sage: sorted(RootSystem(["A",2]).weight_lattice().plot_fundamental_weights(), key=str)
[Arrow from (0.0,0.0) to (0.0,1.0),
 Arrow from (0.0,0.0) to (1.0,0.0),
 Text '$\Lambda_{1}$' at the point (1.05,0.0),
 Text '$\Lambda_{2}$' at the point (0.0,1.05)]

 sage: sorted(RootSystem(["A",2]).ambient_lattice().plot_fundamental_weights(), key=str)
 [Arrow from (0.0,0.0) to (-0.5,0.866024518389),
  Arrow from (0.0,0.0) to (0.5,0.866024518389),
  Text '$\Lambda_{1}$' at the point (0.525,0.909325744308),
  Text '$\Lambda_{2}$' at the point (-0.525,0.909325744308)]
```

plot_hedron(**options*)

Plot the polyhedron whose vertices are given by the orbit of ρ.

In type A, this is the usual permutohedron.

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["A",2]).ambient_space().plot_hedron()
Graphics object consisting of 8 graphics primitives
sage: RootSystem(["A",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["C",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["D",3]).ambient_space().plot_hedron()
Graphics3d Object
```

Surprise: polyhedrons of large dimension know how to project themselves nicely:

```
sage: RootSystem(["F",4]).ambient_space().plot_hedron() # long time
Graphics3d Object
```

TESTS:

```
sage: L = RootSystem(["B",2]).ambient_space()
sage: print L.plot_hedron().description()
```

```
Polygon defined by 8 points: [(1.5, 0.5), (0.5, 1.5), (-0.5, 1.5), (-1.5, 0.5), (-1.5, -
Line defined by 2 points: [(-0.5, -1.5), (0.5, -1.5)]
Line defined by 2 points: [(-0.5, 1.5), (0.5, 1.5)]
Line defined by 2 points: [(-1.5, -0.5), (-0.5, -1.5)]
Line defined by 2 points: [(-1.5, -0.5), (-1.5, 0.5)]
Line defined by 2 points: [(-1.5, 0.5), (-0.5, 1.5)]
Line defined by 2 points: [(0.5, -1.5), (1.5, -0.5)]
Line defined by 2 points: [(0.5, 1.5), (1.5, 0.5)]
Line defined by 2 points: [(1.5, -0.5), (1.5, 0.5)]
Point set defined by 8 point(s): [(-1.5, -0.5), (-1.5, 0.5), (-0.5, -1.5), (-0.5, 1.5),
```

plot_ls_paths(*paths*, *plot_labels=None*, *colored_labels=True*, ***options*)

Plot LS paths.

INPUT:

- `paths` – a finite crystal or list of LS paths
- `plot_labels` – (default: `None`) the distance to plot the LS labels from the endpoint of the path; set to `None` to not display the labels
- `colored_labels` – (default: `True`) if `True`, then color the labels the same color as the LS path
- `**options` – plotting options

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: B = crystals.LSPaths(['A',2], [1,1])
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot_fundamental_weights() + L.plot_ls_paths(B)
Graphics object consisting of 14 graphics primitives
```

This also works in 3 dimensions:

```
sage: B = crystals.LSPaths(['B',3], [2,0,0])
sage: L = RootSystem(['B',3]).ambient_space()
sage: L.plot_ls_paths(B)
Graphics3d Object
```

plot_parse_options(***args*)

Return an option object to be used for root system plotting.

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: options
<sage.combinat.root_system.plot.PlotOptions instance at ...>
```

See also:

- `plot()` for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

plot_reflection_hyperplanes(*collection='simple'*, ***options*)

Plot the simple reflection hyperplanes.

INPUT:

- `collection` – which reflection hyperplanes to display. Can be one of the following:
  - `"simple"` (the default)
  - `"classical"`

- "all"
- **options – Plotting options

See also:

- plot() for a description of the plotting options
- *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["A",2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(["G",2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(["A",3]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["A",3,1]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["B",3,1]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(["A",2,1]).weight_space().plot_reflection_hyperplanes(affine=False, lev
Graphics3d Object
sage: RootSystem(["A",2]).root_lattice().plot_reflection_hyperplanes()
Graphics object consisting of 4 graphics primitives
```

TESTS:

```
sage: L = RootSystem(["A",2]).ambient_space()
sage: print L.plot_reflection_hyperplanes().description()
Text '$H_{\alpha^\vee_{1}}$' at the point (-1.81...,3.15)
Text '$H_{\alpha^\vee_{2}}$' at the point (1.81...,3.15)
Line defined by 2 points: [(-1.73..., 3.0), (1.73..., -3.0)]
Line defined by 2 points: [(1.73..., 3.0), (-1.73..., -3.0)]

sage: print L.plot_reflection_hyperplanes("all").description()
Text '$H_{\alpha^\vee_{1} + \alpha^\vee_{2}}$' at the point (3.15,0.0)
Text '$H_{\alpha^\vee_{1}}$' at the point (-1.81...,3.15)
Text '$H_{\alpha^\vee_{2}}$' at the point (1.81...,3.15)
Line defined by 2 points: [(-1.73..., 3.0), (1.73..., -3.0)]
Line defined by 2 points: [(1.73..., 3.0), (-1.73..., -3.0)]
Line defined by 2 points: [(3.0, 0.0), (-3.0, 0.0)]

sage: L = RootSystem(["A",2,1]).ambient_space()
sage: print L.plot_reflection_hyperplanes().description()
Text '$H_{\alpha^\vee_{0}}$' at the point (3.15,0.90...)
Text '$H_{\alpha^\vee_{1}}$' at the point (-1.81...,3.15)
Text '$H_{\alpha^\vee_{2}}$' at the point (1.81...,3.15)
Line defined by 2 points: [(-1.73..., 3.0), (1.73..., -3.0)]
Line defined by 2 points: [(1.73..., 3.0), (-1.73..., -3.0)]
Line defined by 2 points: [(3.0, 0.86...), (-3.0, 0.86...)]
```

Todo

Provide an option for transparency?

---

plot_roots(*collection='simple'*, ***options*)

Plot the (simple/classical) roots of this root lattice.

INPUT:

- collection – which roots to display can be one of the following:

- "simple" (the default)
- "classical"
- "all"

• **options – Plotting options

See also:

• plot() for a description of the plotting options
• *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```
sage: RootSystem(["B",3]).ambient_space().plot_roots()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_roots("all")
Graphics3d Object
```

TESTS:

```
sage: list(RootSystem(["A",2]).root_lattice().plot_roots())
[Arrow from (0.0,0.0) to (1.0,0.0),
 Text '$\alpha_{1}$' at the point (1.05,0.0),
 Arrow from (0.0,0.0) to (0.0,1.0),
 Text '$\alpha_{2}$' at the point (0.0,1.05)]

sage: list(RootSystem(["A",2]).weight_lattice().plot_roots(labels=False))
[Arrow from (0.0,0.0) to (2.0,-1.0),
 Arrow from (0.0,0.0) to (-1.0,2.0)]

 sage: list(RootSystem(["A",2]).ambient_lattice().plot_roots())
 [Arrow from (0.0,0.0) to (1.5,0.86...),
  Text '$\alpha_{1}$' at the point (1.575,0.90...),
  Arrow from (0.0,0.0) to (-1.5,0.86...),
  Text '$\alpha_{2}$' at the point (-1.575,0.90...)]

 sage: list(RootSystem(["B",2]).ambient_space().plot_roots())
 [Arrow from (0.0,0.0) to (1.0,-1.0),
  Text '$\alpha_{1}$' at the point (1.05,-1.05),
  Arrow from (0.0,0.0) to (0.0,1.0),
  Text '$\alpha_{2}$' at the point (0.0,1.05)]

sage: list(RootSystem(["A",2]).root_lattice().plot_roots("all"))
[Arrow from (0.0,0.0) to (1.0,0.0),
 Text '$\alpha_{1}$' at the point (1.05,0.0),
 Arrow from (0.0,0.0) to (0.0,1.0),
 Text '$\alpha_{2}$' at the point (0.0,1.05),
 Arrow from (0.0,0.0) to (1.0,1.0),
 Text '$\alpha_{1} + \alpha_{2}$' at the point (1.05,1.05),
 Arrow from (0.0,0.0) to (-1.0,0.0),
 Text '$-\alpha_{1}$' at the point (-1.05,0.0),
 Arrow from (0.0,0.0) to (0.0,-1.0),
 Text '$-\alpha_{2}$' at the point (0.0,-1.05),
 Arrow from (0.0,0.0) to (-1.0,-1.0),
 Text '$-\alpha_{1} - \alpha_{2}$' at the point (-1.05,-1.05)]
```

positive_imaginary_roots()

Return the positive imaginary roots of self.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: L.positive_imaginary_roots()
()
```

```
sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PIR = L.positive_imaginary_roots(); PIR
Positive imaginary roots of type ['A', 3, 1]
sage: [PIR.unrank(i) for i in range(5)]
[alpha[0] + alpha[1] + alpha[2] + alpha[3],
 2*alpha[0] + 2*alpha[1] + 2*alpha[2] + 2*alpha[3],
 3*alpha[0] + 3*alpha[1] + 3*alpha[2] + 3*alpha[3],
 4*alpha[0] + 4*alpha[1] + 4*alpha[2] + 4*alpha[3],
 5*alpha[0] + 5*alpha[1] + 5*alpha[2] + 5*alpha[3]]
```

positive_real_roots()

Return the positive real roots of `self`.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_real_roots())
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3],
 alpha[2], alpha[2] + alpha[3], alpha[3]]

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PRR = L.positive_real_roots(); PRR
Positive real roots of type ['A', 3, 1]
sage: [PRR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
 alpha[1] + alpha[2] + alpha[3],
 alpha[0] + 2*alpha[1] + alpha[2] + alpha[3],
 alpha[0] + alpha[1] + 2*alpha[2] + alpha[3],
 alpha[0] + alpha[1] + alpha[2] + 2*alpha[3],
 alpha[0] + 2*alpha[1] + 2*alpha[2] + alpha[3]]

sage: Q = RootSystem(['A',4,2]).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 2*alpha[1] + alpha[2],
 alpha[1] + alpha[2],
 alpha[0] + alpha[1] + alpha[2]]

sage: Q = RootSystem(['D',3,2]).root_lattice()
sage: PR = Q.positive_roots()
sage: [PR.unrank(i) for i in range(5)]
[alpha[1],
 alpha[2],
 alpha[1] + 2*alpha[2],
 alpha[1] + alpha[2],
 alpha[0] + alpha[1] + 2*alpha[2]]
```

positive_roots(*index_set=None*)

Return the positive roots of `self`.

If `index_set` is not `None`, returns the positive roots of the parabolic subsystem with simple roots in `index_set`.

Algorithm for finite type: generate them from the simple roots by applying successive reflections

toward the positive chamber.

EXAMPLES:

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_roots())
[alpha[1], alpha[1] + alpha[2],
 alpha[1] + alpha[2] + alpha[3], alpha[2],
 alpha[2] + alpha[3], alpha[3]]
sage: sorted(L.positive_roots((1,2)))
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: sorted(L.positive_roots(()))
[]

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PR = L.positive_roots(); PR
Disjoint union of Family (Positive real roots of type ['A', 3, 1],
    Positive imaginary roots of type ['A', 3, 1])
sage: [PR.unrank(i) for i in range(10)]
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
 alpha[1] + alpha[2] + alpha[3],
 alpha[0] + 2*alpha[1] + alpha[2] + alpha[3],
 alpha[0] + alpha[1] + 2*alpha[2] + alpha[3],
 alpha[0] + alpha[1] + alpha[2] + 2*alpha[3],
 alpha[0] + 2*alpha[1] + 2*alpha[2] + alpha[3]]
```

positive_roots_by_height(*increasing=True*)

Returns a list of positive roots in increasing order by height.

If `increasing` is False, returns them in decreasing order.

Warning: Raise an error if the Cartan type is not finite.

EXAMPLES:

```
sage: L = RootSystem(['C',2]).root_lattice()
sage: L.positive_roots_by_height()
[alpha[2], alpha[1], alpha[1] + alpha[2], 2*alpha[1] + alpha[2]]
sage: L.positive_roots_by_height(increasing = False)
[2*alpha[1] + alpha[2], alpha[1] + alpha[2], alpha[2], alpha[1]]

sage: L = RootSystem(['A',2,1]).root_lattice()
sage: L.positive_roots_by_height()
Traceback (most recent call last):
...
NotImplementedError: Only implemented for finite Cartan type
```

positive_roots_nonparabolic(*index_set=None*)

Returns the set of positive roots outside the parabolic subsystem with Dynkin node set `index_set`.

INPUT:

- `index_set` – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```
sage: lattice =  RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_nonparabolic((1,3)), key=str)
```

```
[alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3], alpha[2], alpha[2] + alpha[3]]
sage: sorted(lattice.positive_roots_nonparabolic((2,3)), key=str)
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3]]
sage: lattice.positive_roots_nonparabolic()
[]
sage: lattice.positive_roots_nonparabolic((1,2,3))
[]
```

Warning: This returns an error if the Cartan type is not finite.

positive_roots_nonparabolic_sum(*index_set=None*)

Returns the sum of positive roots outside the parabolic subsystem with Dynkin node set `index_set`.

INPUT:

- `index_set` – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: lattice.positive_roots_nonparabolic_sum((1,3))
2*alpha[1] + 4*alpha[2] + 2*alpha[3]
sage: lattice.positive_roots_nonparabolic_sum((2,3))
3*alpha[1] + 2*alpha[2] + alpha[3]
sage: lattice.positive_roots_nonparabolic_sum(())
3*alpha[1] + 4*alpha[2] + 3*alpha[3]
sage: lattice.positive_roots_nonparabolic_sum()
0
sage: lattice.positive_roots_nonparabolic_sum((1,2,3))
0
```

Warning: This returns an error if the Cartan type is not finite.

positive_roots_parabolic(*index_set=None*)

Return the set of positive roots for the parabolic subsystem with Dynkin node set `index_set`.

INPUT:

- `index_set` – (default:None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

```
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_parabolic((1,3)), key=str)
[alpha[1], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((2,3)), key=str)
[alpha[2], alpha[2] + alpha[3], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic(), key=str)
[alpha[1], alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3], alpha[2], alpha[2] + alpl
```

Warning: This returns an error if the Cartan type is not finite.

projection(*root*, *coroot=None*, *to_negative=True*)

Returns the projection along the root, and across the hyperplane define by coroot, as a function π from self to self. π is a half-linear map which stabilizes the negative half space, and acts by reflection on the positive half space.

If to_negative is False, then this project onto the positive half space instead.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x=space.simple_roots()[1]
sage: y=space.simple_coroots()[1]
sage: pi = space.projection(x,y)
sage: x
2*Lambda[1] - Lambda[2]
sage: pi(x)
-2*Lambda[1] + Lambda[2]
sage: pi(-x)
-2*Lambda[1] + Lambda[2]
sage: pi = space.projection(x,y,False)
sage: pi(-x)
2*Lambda[1] - Lambda[2]
```

reflection(*root*, *coroot=None*)

Returns the reflection along the root, and across the hyperplane define by coroot, as a function from self to self.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x=space.simple_roots()[1]
sage: y=space.simple_coroots()[1]
sage: s = space.reflection(x,y)
sage: x
2*Lambda[1] - Lambda[2]
sage: s(x)
-2*Lambda[1] + Lambda[2]
sage: s(-x)
2*Lambda[1] - Lambda[2]
```

root_poset(*restricted=False*, *facade=False*)

Returns the (restricted) root poset associated to `self`.

The elements are given by the positive roots (resp. non-simple, positive roots), and $\alpha \leq \beta$ iff $\beta - \alpha$ is a non-negative linear combination of simple roots.

INPUT:

- `restricted` – (default:False) if True, only non-simple roots are considered.
- `facade` – (default:False) passes facade option to the poset generator.

EXAMPLES:

```
sage: Phi = RootSystem(['A',1]).root_poset(); Phi
Finite poset containing 1 elements
sage: Phi.cover_relations()
[]

sage: Phi = RootSystem(['A',2]).root_poset(); Phi
Finite poset containing 3 elements

sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1], alpha[1] + alpha[2]], [alpha[2], alpha[1] + alpha[2]]]

sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3]], [alpha[2] + alpha[3], alpha[1] +

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements
```

```
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1] + alpha[2], alpha[1] + 2*alpha[2]],
 [alpha[1], alpha[1] + alpha[2]],
 [alpha[2], alpha[1] + alpha[2]]]
```

TESTS:

Check that trac ticket #17982 is fixed:

```
sage: RootSystem(['A', 2]).ambient_space().root_poset()
Finite poset containing 3 elements
```

roots()

Return the roots of `self`.

EXAMPLES:

```
sage: RootSystem(['A',2]).ambient_lattice().roots()
[(1, -1, 0), (1, 0, -1), (0, 1, -1), (-1, 1, 0), (-1, 0, 1), (0, -1, 1)]
```

This matches with Wikipedia article Root_systems:

```
sage: for T in CartanType.samples(finite = True, crystallographic = True):
...       print "%s %3s %3s"%(T, len(RootSystem(T).root_lattice().roots()), len(RootSyst
['A', 1]   2   2
['A', 5]  30  30
['B', 1]   2   2
['B', 5]  50  50
['C', 1]   2   2
['C', 5]  50  50
['D', 2]   4   4
['D', 3]  12  12
['D', 5]  40  40
['E', 6]  72  72
['E', 7] 126 126
['E', 8] 240 240
['F', 4]  48  48
['G', 2]  12  12
```

Todo

The result should be an enumerated set, and handle infinite root systems.

---

s()

Returns the family $(s_i)_{i \in I}$ of the simple reflections of this root system.

EXAMPLES:

```
sage: r = RootSystem(["A", 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]
```

TEST:

```
sage: s
simple reflections
```

short_roots()

Return a list of the short roots of `self`.

EXAMPLES:

```
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.short_roots())
[-alpha[1] - alpha[2] - alpha[3],
 alpha[1] + alpha[2] + alpha[3],
 -alpha[2] - alpha[3],
 alpha[2] + alpha[3],
 -alpha[3],
 alpha[3]]
```

simple_coroot(*i*)

Returns the i^{th} simple coroot.

EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().simple_coroot(1)
alphacheck[1]
```

simple_coroots()

Returns the family $(\alpha_i^\vee)_{i\in I}$ of the simple coroots.

EXAMPLES:

```
sage: alphacheck = RootSystem(['A',3]).root_lattice().simple_coroots()
sage: [alphacheck[i] for i in [1, 2, 3]]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

simple_projection(*i*, *to_negative=True*)

Returns the projection along the i^{th} simple root, and across the hyperplane define by the i^{th} simple coroot, as a function from self to self.

INPUT:

- `i` - i is in self's index set

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: pi = space.simple_projection(1)
sage: x
2*Lambda[1] - Lambda[2]
sage: pi(x)
-2*Lambda[1] + Lambda[2]
sage: pi(-x)
-2*Lambda[1] + Lambda[2]
sage: pi = space.simple_projection(1,False)
sage: pi(-x)
2*Lambda[1] - Lambda[2]
```

simple_projections(*to_negative=True*)

Returns the family $(s_i)_{i\in I}$ of the simple projections of this root system

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: pi = space.simple_projections()
sage: x = space.simple_roots()
sage: pi[1](x[2])
-Lambda[1] + 2*Lambda[2]
```

TESTS: sage: pi pi

simple_reflection(*i*)

Returns the i^{th} simple reflection, as a function from self to self.

INPUT:

- i - i is in self's index set

EXAMPLES:

```
sage: space = RootSystem(['A',2]).ambient_lattice()
sage: s = space.simple_reflection(1)
sage: x = space.simple_roots()[1]
sage: x
(1, -1, 0)
sage: s(x)
(-1, 1, 0)
```

simple_reflections()

Returns the family $(s_i)_{i \in I}$ of the simple reflections of this root system.

EXAMPLES:

```
sage: r = RootSystem(["A", 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )
-alpha[1]
```

TEST:

```
sage: s
simple reflections
```

simple_root(i)

Returns the i^{th} simple root.

This should be overridden by any subclass, and typically implemented as a cached method for efficiency.

EXAMPLES:

```
sage: r = RootSystem(["A",3]).root_lattice()
sage: r.simple_root(1)
alpha[1]
```

TESTS:

```
sage: super(sage.combinat.root_system.root_space.RootSpace, r).simple_root(1)
Traceback (most recent call last):
...
NotImplementedError: <abstract method simple_root at ...>
```

simple_roots()

Returns the family $(\alpha_i)_{i \in I}$ of the simple roots.

EXAMPLES:

```
sage: alpha = RootSystem(["A",3]).root_lattice().simple_roots()
sage: [alpha[i] for i in [1,2,3]]
[alpha[1], alpha[2], alpha[3]]
```

simple_roots_tilde()

Return the family $(\tilde{\alpha}_i)_{i \in I}$ of the simple roots.

INPUT:

- self – an affine root lattice realization

The $\tilde{\alpha}_i$ give the embedding of the root lattice of the other affinization of the same classical root lattice into this root lattice (space?).

This uses the fact that $\alpha_i = \tilde{\alpha}_i$ for i not a special node, and that

$$\delta = \sum a_i \alpha_i = \sum b_i \tilde{\alpha}_i$$

EXAMPLES:

In simply laced cases, this is boring:

```
sage: RootSystem(["A",3, 1]).root_lattice().simple_roots_tilde()
Finite family {0: alpha[0], 1: alpha[1], 2: alpha[2], 3: alpha[3]}
```

This was checked by hand:

```
sage: RootSystem(["C",2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[2], 1: alphacheck[1], 2: alphacheck[2]}
sage: RootSystem(["B",2,1]).coroot_lattice().simple_roots_tilde()
Finite family {0: alphacheck[0] - alphacheck[1], 1: alphacheck[1], 2: alphacheck[2]}
```

What about type BC?

some_elements()

Return some elements of this root lattice realization

EXAMPLES:

```
sage: L = RootSystem(["A",2]).weight_lattice()
sage: L.some_elements()
[2*Lambda[1] + 2*Lambda[2], 2*Lambda[1] - Lambda[2], -Lambda[1] + 2*Lambda[2], Lambda[1]
sage: L = RootSystem(["A",2]).root_lattice()
sage: L.some_elements()
[2*alpha[1] + 2*alpha[2], alpha[1], alpha[2]]
```

tau_epsilon_operator_on_almost_positive_roots(J)

The τ_ϵ operator on almost positive roots

Given a subset J of non adjacent vertices of the Dynkin diagram, this constructs the operator on the almost positive roots which fixes the negative simple roots α_i for i not in J, and acts otherwise by:

$$\tau_+(\beta) = (\prod_{i \in J} s_i)(\beta)$$

See Equation (1.2) of [CFZ].

EXAMPLES:

```
sage: L = RootSystem(['A',4]).root_lattice()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: alpha = L.simple_roots()
```

The action on a negative simple root not in J:

```
sage: tau(-alpha[2])
-alpha[2]
```

The action on a negative simple root in J:

```
sage: tau(-alpha[1])
alpha[1]
```

The action on all almost positive roots:

```
sage: for root in L.almost_positive_roots():
...       print 'tau({:<41}) ='.format(root), tau(root)
tau(-alpha[1]                                ) = alpha[1]
tau(alpha[1]                                 ) = -alpha[1]
tau(alpha[1] + alpha[2]                      ) = alpha[2] + alpha[3]
tau(alpha[1] + alpha[2] + alpha[3]           ) = alpha[2]
tau(alpha[1] + alpha[2] + alpha[3] + alpha[4]) = alpha[2] + alpha[3] + alpha[4]
tau(-alpha[2]                                ) = -alpha[2]
tau(alpha[2]                                 ) = alpha[1] + alpha[2] + alpha[3]
```

```
tau(alpha[2] + alpha[3]                          ) = alpha[1] + alpha[2]
tau(alpha[2] + alpha[3] + alpha[4]               ) = alpha[1] + alpha[2] + alpha[3] + alpha[
tau(-alpha[3]                                    ) = alpha[3]
tau(alpha[3]                                     ) = -alpha[3]
tau(alpha[3] + alpha[4]                          ) = alpha[4]
tau(-alpha[4]                                    ) = -alpha[4]
tau(alpha[4]                                     ) = alpha[3] + alpha[4]
```

This method works on any root lattice realization:

```
sage: L = RootSystem(['B',3]).ambient_space()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])
sage: for root in L.almost_positive_roots():
...       print 'tau({:<41}) ='.format(root), tau(root)
tau((-1, 1, 0)                                   ) = (1, -1, 0)
tau((1, 0, 0)                                    ) = (0, 1, 0)
tau((1, -1, 0)                                   ) = (-1, 1, 0)
tau((1, 1, 0)                                    ) = (1, 1, 0)
tau((1, 0, -1)                                   ) = (0, 1, 1)
tau((1, 0, 1)                                    ) = (0, 1, -1)
tau((0, -1, 1)                                   ) = (0, -1, 1)
tau((0, 1, 0)                                    ) = (1, 0, 0)
tau((0, 1, -1)                                   ) = (1, 0, 1)
tau((0, 1, 1)                                    ) = (1, 0, -1)
tau((0, 0, -1)                                   ) = (0, 0, 1)
tau((0, 0, 1)                                    ) = (0, 0, -1)
```

See also:

`tau_plus_minus()`

REFERENCES:

tau_plus_minus()

Returns the τ^+ and τ^- piecewise linear operators on `self`

Those operators are induced by the bipartition $\{L, R\}$ of the simple roots of `self`, and stabilize the almost positive roots. Namely, τ_+ fixes the negative simple roots α_i for i in R, and acts otherwise by:

$$\tau_+(\beta) = (\prod_{i \in L} s_i)(\beta)$$

τ_- acts analogously, with L and R interchanged.

Those operators are used to construct the associahedron, a polytopal realization of the cluster complex (see `Associahedron`).

See also:

`tau_epsilon_operator_on_almost_positive_roots()`

EXAMPLES:

We explore the example of [CFZ] Eq.(1.3):

```
sage: S = RootSystem(['A',2]).root_lattice()
sage: taup, taum = S.tau_plus_minus()
sage: for beta in S.almost_positive_roots(): print beta, ",", taup(beta), ",", taum(beta
-alpha[1] , alpha[1] , -alpha[1]
alpha[1] , -alpha[1] , alpha[1] + alpha[2]
alpha[1] + alpha[2] , alpha[2] , alpha[1]
-alpha[2] , -alpha[2] , alpha[2]
alpha[2] , alpha[1] + alpha[2] , -alpha[2]
```

to_ambient_space_morphism()
Return the morphism to the ambient space.

EXAMPLES:

```
sage: CartanType(['B',2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
From: Root lattice of the Root system of type ['B', 2]
To:   Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B',2]).root_system().coroot_lattice().to_ambient_space_morphism()
Generic morphism:
From: Coroot lattice of the Root system of type ['B', 2]
To:   Ambient space of the Root system of type ['B', 2]
sage: CartanType(['B',2]).root_system().weight_lattice().to_ambient_space_morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['B', 2]
To:   Ambient space of the Root system of type ['B', 2]
```

weyl_group(*prefix=None*)
Returns the Weyl group associated to self.

EXAMPLES:

```
sage: RootSystem(['F',4]).ambient_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the ambient space)
sage: RootSystem(['F',4]).root_space().weyl_group()
Weyl Group of type ['F', 4] (as a matrix group acting on the root space)
```

RootLatticeRealizations.**super_categories**()
EXAMPLES:

```
sage: from sage.combinat.root_system.root_lattice_realizations import RootLatticeRealization
sage: RootLatticeRealizations(QQ).super_categories()
[Category of vector spaces with basis over Rational Field]
```

5.1.209 Root lattices and root spaces

class sage.combinat.root_system.root_space.**RootSpace**(*root_system*, *base_ring*)
Bases: sage.misc.cachefunc.ClearCacheOnPickle, sage.combinat.free_module.CombinatorialFree

The root space of a root system over a given base ring

INPUT:

- root_system - a root system
- base_ring: a ring R

The *root space* (or lattice if base_ring is $\mathbf{Z}$) of a root system is the formal free module $\bigoplus_i R\alpha_i$ generated by the simple roots $(\alpha_i)_{i\in I}$ of the root system.

This class is also used for coroot spaces (or lattices).

See also:

- RootSystem()
- RootSystem.root_lattice() and RootSystem.root_space()
- RootLatticeRealizations()

Todo: standardize the variable used for the root space in the examples (P?)

TESTS:

```
sage: for ct in CartanType.samples(crystallographic=True)+[CartanType(["A",2],["C",5,1])]:
...       TestSuite(ct.root_system().root_lattice()).run()
...       TestSuite(ct.root_system().root_space()).run()
sage: r = RootSystem(['A',4]).root_lattice()
sage: r.simple_root(1)
alpha[1]
sage: latex(r.simple_root(1))
\alpha_{1}
```

Element
alias of RootSpaceElement

simple_root()
Return the basis element indexed by i.

INPUT:

- i – an element of the index set

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

F.monomial is in fact (almost) a map:

```
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over Rational Fiel
```

to_ambient_space_morphism()
The morphism from self to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A',2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
From: Root lattice of the Root system of type ['A', 2]
To:   Ambient space of the Root system of type ['A', 2]
```

to_coroot_space_morphism()
Returns the nu map to the coroot space over the same base ring, using the symmetrizer of the Cartan matrix

It does not map the root lattice to the coroot lattice, but has the property that any root is mapped to some scalar multiple of its associated coroot.

EXAMPLES:

```
sage: R = RootSystem(['A',3]).root_space()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
alphacheck[1] + alphacheck[2]

sage: R = RootSystem(['A',3]).root_lattice()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()
sage: f(alpha[1])
```

```
alphacheck[1]
sage: f(alpha[1]+alpha[2])
alphacheck[1] + alphacheck[2]

sage: S = RootSystem(['G',2]).root_space()
sage: alpha = S.simple_roots()
sage: f = S.to_coroot_space_morphism()
sage: f(alpha[1])
alphacheck[1]
sage: f(alpha[1]+alpha[2])
alphacheck[1] + 3*alphacheck[2]
```

class sage.combinat.root_system.root_space.**RootSpaceElement**(M, x)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

associated_coroot()

Returns the coroot associated to this root

OUTPUT:

An element of the coroot space over the same base ring; in particular the result is in the coroot lattice whenever self is in the root lattice.

EXAMPLES:

```
sage: L = RootSystem(["B", 3]).root_space()
sage: alpha = L.simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
sage: alpha[1].associated_coroot().parent()
Coroot space over the Rational Field of the Root system of type ['B', 3]

sage: L.highest_root()
alpha[1] + 2*alpha[2] + 2*alpha[3]
sage: L.highest_root().associated_coroot()
alphacheck[1] + 2*alphacheck[2] + alphacheck[3]

sage: alpha = RootSystem(["B", 3]).root_lattice().simple_roots()
sage: alpha[1].associated_coroot()
alphacheck[1]
sage: alpha[1].associated_coroot().parent()
Coroot lattice of the Root system of type ['B', 3]
```

is_positive_root()

Checks whether an element in the root space lies in the nonnegative cone spanned by the simple roots.

EXAMPLES:

```
sage: R=RootSystem(['A',3,1]).root_space()
sage: B=R.basis()
sage: w=B[0]+B[3]
sage: w.is_positive_root()
True
sage: w=B[1]-B[2]
sage: w.is_positive_root()
False
```

max_coroot_le()

Returns the highest positive coroot whose associated root is less than or equal to `self`.

INPUT:

- `self` – an element of the nonnegative integer span of simple roots.

Returns None for the zero element.

Really `self` is an element of a coroot lattice and this method returns the highest root whose associated coroot is <= `self`.

Warning: This implementation only handles finite Cartan types

EXAMPLES:

```
sage: root_lattice = RootSystem(['C',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
alphacheck[1] + 2*alphacheck[2]
sage: root_lattice.from_vector(vector([2,1])).max_coroot_le()
alphacheck[1] + 2*alphacheck[2]
sage: root_lattice = RootSystem(['B',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
2*alphacheck[1] + alphacheck[2]
sage: root_lattice.from_vector(vector([1,2])).max_coroot_le()
2*alphacheck[1] + alphacheck[2]

sage: root_lattice.zero().max_coroot_le() is None
True
sage: root_lattice.from_vector(vector([-1,0])).max_coroot_le()
Traceback (most recent call last):
...
ValueError: -alpha[1] is not in the positive cone of roots
sage: root_lattice = RootSystem(['A',2,1]).root_lattice()
sage: root_lattice.simple_root(1).max_coroot_le()
Traceback (most recent call last):
...
NotImplementedError: Only implemented for finite Cartan type
```

max_quantum_element()

Returns a reduced word for the longest element of the Weyl group whose shortest path in the quantum Bruhat graph to the identity, has sum of quantum coroots at most `self`.

INPUT:

- `self` – an element of the nonnegative integer span of simple roots.

Really `self` is an element of a coroot lattice.

Warning: This implementation only handles finite Cartan types

EXAMPLES:

```
sage: Qvee = RootSystem(['C',2]).coroot_lattice()
sage: Qvee.from_vector(vector([1,2])).max_quantum_element()
[2, 1, 2, 1]
sage: Qvee.from_vector(vector([1,1])).max_quantum_element()
[1, 2, 1]
sage: Qvee.from_vector(vector([0,2])).max_quantum_element()
[2]
```

quantum_root()

Returns True if `self` is a quantum root and False otherwise.

INPUT:

- `self` – an element of the nonnegative integer span of simple roots.

A root α is a quantum root if $\ell(s_\alpha) = \langle 2\rho, \alpha^\vee \rangle - 1$ where ℓ is the length function, s_α is the reflection across the hyperplane orthogonal to α, and 2ρ is the sum of positive roots.

Warning: This implementation only handles finite Cartan types and assumes that `self` is a root.

Todo

Rename to is_quantum_root

EXAMPLES:

```
sage: Q = RootSystem(['C',2]).root_lattice()
sage: positive_roots = Q.positive_roots()
sage: for x in positive_roots:
....:     print x, x.quantum_root()
alpha[1] True
alpha[2] True
2*alpha[1] + alpha[2] True
alpha[1] + alpha[2] False
```

scalar(*lambdacheck*)

The scalar product between the root lattice and the coroot lattice.

EXAMPLES:

```
sage: L = RootSystem(['B',4]).root_lattice()
sage: alpha      = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])
2
sage: alpha[1].scalar(alphacheck[2])
-1
```

The scalar products between the roots and coroots are given by the Cartan matrix:

```
sage: matrix([ [ alpha[i].scalar(alphacheck[j])
...              for i in L.index_set() ]
...            for j in L.index_set() ])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -2  2]
```

```
sage: L.cartan_type().cartan_matrix()
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -2  2]
```

to_ambient()

Map `self` to the ambient space.

EXAMPLES:

```
sage: alpha = CartanType(['B',2]).root_system().root_lattice().an_element(); alpha
2*alpha[1] + 2*alpha[2]
sage: alpha.to_ambient()
(2, 0)
sage: alphavee = CartanType(['B',2]).root_system().coroot_lattice().an_element(); alphavee
2*alphacheck[1] + 2*alphacheck[2]
sage: alphavee.to_ambient()
(2, 2)
```

5.1.210 Root systems

See *Root Systems* for an overview.

class sage.combinat.root_system.root_system.**RootSystem**(*cartan_type*, *as_dual_of=None*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A class for root systems.

EXAMPLES:

We construct the root system for type B_3:

```
sage: R=RootSystem(['B',3]); R
Root system of type ['B', 3]
```

`R` models the root system abstractly. It comes equipped with various realizations of the root and weight lattices, where all computations take place. Let us play first with the root lattice:

```
sage: space = R.root_lattice()
sage: space
Root lattice of the Root system of type ['B', 3]
```

This is the free $\mathbf{Z}$-module $\bigoplus_i \mathbf{Z}.\alpha_i$ spanned by the simple roots:

```
sage: space.base_ring()
Integer Ring
sage: list(space.basis())
[alpha[1], alpha[2], alpha[3]]
```

Let us do some computations with the simple roots:

```
sage: alpha = space.simple_roots()
sage: alpha[1] + alpha[2]
alpha[1] + alpha[2]
```

There is a canonical pairing between the root lattice and the coroot lattice:

```
sage: R.coroot_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

We construct the simple coroots, and do some computations (see comments about duality below for some caveat):

```
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

We can carry over the same computations in any of the other realizations of the root lattice, like the root space $\bigoplus_i \mathbf{Q}.\alpha_i$, the weight lattice $\bigoplus_i \mathbf{Z}.\Lambda_i$, the weight space $\bigoplus_i \mathbf{Q}.\Lambda_i$. For example:

```
sage: space = R.weight_space()
sage: space
Weight space over the Rational Field of the Root system of type ['B', 3]

sage: space.base_ring()
Rational Field
sage: list(space.basis())
[Lambda[1], Lambda[2], Lambda[3]]

sage: alpha = space.simple_roots()
sage: alpha[1] + alpha[2]
Lambda[1] + Lambda[2] - 2*Lambda[3]
```

The fundamental weights are the dual basis of the coroots:

```
sage: Lambda = space.fundamental_weights()
sage: Lambda[1]
Lambda[1]

sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]

sage: [Lambda[i].scalar(alphacheck[1]) for i in space.index_set()]
[1, 0, 0]
sage: [Lambda[i].scalar(alphacheck[2]) for i in space.index_set()]
[0, 1, 0]
sage: [Lambda[i].scalar(alphacheck[3]) for i in space.index_set()]
[0, 0, 1]
```

Let us use the simple reflections. In the weight space, they work as in the *number game*: firing the node i on an element x adds c times the simple root α_i, where c is the coefficient of i in x:

```
sage: s = space.simple_reflections()
sage: Lambda[1].simple_reflection(1)
-Lambda[1] + Lambda[2]
sage: Lambda[2].simple_reflection(1)
Lambda[2]
sage: Lambda[3].simple_reflection(1)
Lambda[3]
sage: (-2*Lambda[1] + Lambda[2] + Lambda[3]).simple_reflection(1)
2*Lambda[1] - Lambda[2] + Lambda[3]
```

It can be convenient to manipulate the simple reflections themselves:

```
sage: s = space.simple_reflections()
sage: s[1](Lambda[1])
-Lambda[1] + Lambda[2]
sage: s[1](Lambda[2])
Lambda[2]
sage: s[1](Lambda[3])
Lambda[3]
```

Ambient spaces

The root system may also come equipped with an ambient space. This is a $\mathbf{Q}$-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings of the (extended) weight and the (extended) coweight lattice, and therefore the root and the coroot lattice. This is implemented on a type by type basis for the finite crystallographic root systems following Bourbaki's conventions and is extended to the affine cases. Coefficients permitting, this is also available as an ambient lattice.

See also:

`ambient_space()` and `ambient_lattice()` for details

In finite type A, we recover the natural representation of the symmetric group as group of permutation matrices:

```
sage: RootSystem(["A",2]).ambient_space().weyl_group().simple_reflections()
Finite family {1: [0 1 0]
                  [1 0 0]
                  [0 0 1],
               2: [1 0 0]
                  [0 0 1]
                  [0 1 0]}
```

In type B, C, and D, we recover the natural representation of the Weyl group as groups of signed permutation matrices:

```
sage: RootSystem(["B",3]).ambient_space().weyl_group().simple_reflections()
Finite family {1: [0 1 0]
                  [1 0 0]
                  [0 0 1],
               2: [1 0 0]
                  [0 0 1]
                  [0 1 0],
               3: [ 1  0  0]
                  [ 0  1  0]
                  [ 0  0 -1]}
```

In (untwisted) affine types A, ..., D, one can recover from the ambient space the affine permutation representation, in window notation. Let us consider the ambient space for affine type A:

```
sage: L = RootSystem(["A",2,1]).ambient_space(); L
Ambient space of the Root system of type ['A', 2, 1]
```

Define the "identity" by an appropriate vector at level -3:

```
sage: e = L.basis(); Lambda = L.fundamental_weights()
sage: id = e[0] + 2*e[1] + 3*e[2]  - 3*Lambda[0]
```

The corresponding permutation is obtained by projecting it onto the classical ambient space:

```
sage: L.classical()
Ambient space of the Root system of type ['A', 2]
sage: L.classical()(id)
(1, 2, 3)
```

Here is the orbit of the identity under the action of the finite group:

```
sage: W = L.weyl_group()
sage: S3 = [ w.action(id) for w in W.classical() ]
sage: [L.classical()(x) for x in S3]
[(1, 2, 3), (3, 2, 1), (3, 1, 2), (2, 1, 3), (2, 3, 1), (1, 3, 2)]
```

And the action of s_0 on these yields:

```
sage: s = W.simple_reflections()
sage: [L.classical()(s[0].action(x)) for x in S3]
[(0, 2, 4), (-2, 2, 6), (-1, 1, 6), (0, 1, 5), (-2, 3, 5), (-1, 3, 4)]
```

We can also plot various components of the ambient spaces:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

For more on plotting, see *Tutorial: visualizing root systems*.

Dual root systems

The root system is aware of its dual root system:

```
sage: R.dual
Dual of root system of type ['B', 3]
```

`R.dual` is really the root system of type C_3:

```
sage: R.dual.cartan_type()
['C', 3]
```

And the coroot lattice that we have been manipulating before is really implemented as the root lattice of the dual root system:

```
sage: R.dual.root_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

In particular, the coroots for the root lattice are in fact the roots of the coroot lattice:

```
sage: list(R.root_lattice().simple_coroots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.coroot_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.dual.root_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

The coweight lattice and space are defined similarly. Note that, to limit confusion, all the output have been tweaked appropriately.

See also:

- `sage.combinat.root_system`

- RootSpace
- WeightSpace
- AmbientSpace
- RootLatticeRealizations
- WeightLatticeRealizations

TESTS:

```
sage: R = RootSystem(['C',3])
sage: TestSuite(R).run()
sage: L = R.ambient_space()
sage: s = L.simple_reflections() # this used to break the testsuite below due to caching an unpi
sage: s = L.simple_projections() # todo: not implemented
sage: TestSuite(L).run()
sage: L = R.root_space()
sage: s = L.simple_reflections()
sage: TestSuite(L).run()

sage: for T in CartanType.samples(crystallographic=True):  # long time (13s on sage.math, 2012)
...       TestSuite(RootSystem(T)).run()
```

ambient_lattice()

Return the ambient lattice for this root_system.

This is the ambient space, over **Z**.

See also:

- ambient_space()
- root_lattice()
- weight_lattice()

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4]
sage: RootSystem(['A',4,1]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4, 1]
```

Except in type A, only an ambient space can be realized:

```
sage: RootSystem(['B',4]).ambient_lattice()
sage: RootSystem(['C',4]).ambient_lattice()
sage: RootSystem(['D',4]).ambient_lattice()
sage: RootSystem(['E',6]).ambient_lattice()
sage: RootSystem(['F',4]).ambient_lattice()
sage: RootSystem(['G',2]).ambient_lattice()
```

ambient_space(*base_ring=Rational Field*)

Return the usual ambient space for this root_system.

INPUT:

- base_ring – a base ring (default: **Q**)

This is a base_ring-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings into the weight and the coweight lattice, and therefore the root and the coroot lattice,

and preserves scalar products between elements of the coroot lattice and elements of the root or weight lattice (and dually).

There is no mechanical way to define the ambient space just from the Cartan matrix. Instead is is constructed from hard coded type by type data, according to the usual Bourbaki conventions. Such data is provided for all the finite (crystallographic) types. From this data, ambient spaces can be built as well for dual types, reducible types and affine types. When no data is available, or if the base ring is not large enough, None is returned.

Warning: for affine types

See also:

- The section on ambient spaces in RootSystem
- ambient_lattice()
- AmbientSpace
- AmbientSpace
- root_space()
- weight:space()

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_space()
Ambient space of the Root system of type ['A', 4]

sage: RootSystem(['B',4]).ambient_space()
Ambient space of the Root system of type ['B', 4]

sage: RootSystem(['C',4]).ambient_space()
Ambient space of the Root system of type ['C', 4]

sage: RootSystem(['D',4]).ambient_space()
Ambient space of the Root system of type ['D', 4]

sage: RootSystem(['E',6]).ambient_space()
Ambient space of the Root system of type ['E', 6]

sage: RootSystem(['F',4]).ambient_space()
Ambient space of the Root system of type ['F', 4]

sage: RootSystem(['G',2]).ambient_space()
Ambient space of the Root system of type ['G', 2]
```

An alternative base ring can be provided as an option:

```
sage: e = RootSystem(['B',3]).ambient_space(RR)
sage: TestSuite(e).run()
```

It should contain the smallest ring over which the ambient space can be defined ($\mathbf{Z}$ in type A or $\mathbf{Q}$ otherwise). Otherwise None is returned:

```
sage: RootSystem(['B',2]).ambient_space(ZZ)
```

The base ring should also be totally ordered. In practice, only $\mathbf{Z}$ and $\mathbf{Q}$ are really supported at this point, but you are welcome to experiment:

```
sage: e = RootSystem(['G',2]).ambient_space(RR)
sage: TestSuite(e).run()
Failure in _test_root_lattice_realization:
Traceback (most recent call last):
...
AssertionError: 2.00000000000000 != 2.00000000000000
----------------------------------------------------------------------
The following tests failed: _test_root_lattice_realization
```

cartan_matrix()

EXAMPLES:

```
sage: RootSystem(['A',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
```

cartan_type()

Returns the Cartan type of the root system.

EXAMPLES:

```
sage: R = RootSystem(['A',3])
sage: R.cartan_type()
['A', 3]
```

coambient_space(*base_ring=Rational Field*)

Return the coambient space for this root system.

This is the ambient space of the dual root system.

See also:

- ambient_space()

EXAMPLES:

```
sage: L = RootSystem(["B",2]).ambient_space(); L
Ambient space of the Root system of type ['B', 2]
sage: coL = RootSystem(["B",2]).coambient_space(); coL
Coambient space of the Root system of type ['B', 2]
```

The roots and coroots are interchanged:

```
sage: coL.simple_roots()
Finite family {1: (1, -1), 2: (0, 2)}
sage: L.simple_coroots()
Finite family {1: (1, -1), 2: (0, 2)}

sage: coL.simple_coroots()
Finite family {1: (1, -1), 2: (0, 1)}
sage: L.simple_roots()
Finite family {1: (1, -1), 2: (0, 1)}
```

coroot_lattice()

Returns the coroot lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).coroot_lattice()
Coroot lattice of the Root system of type ['A', 3]
```

coroot_space(*base_ring=Rational Field*)
Returns the coroot space associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 3]
```

coweight_lattice(*extended=False*)
Returns the coweight lattice associated to self.

This is the weight lattice of the dual root system.

EXAMPLES:

```
sage: RootSystem(['A',3]).coweight_lattice()
Coweight lattice of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).coweight_lattice(extended = True)
Extended coweight lattice of the Root system of type ['A', 3, 1]
```

coweight_space(*base_ring=Rational Field*, *extended=False*)
Returns the coweight space associated to self.

This is the weight space of the dual root system.

EXAMPLES:

```
sage: RootSystem(['A',3]).coweight_space()
Coweight space over the Rational Field of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).coweight_space(extended=True)
Extended coweight space over the Rational Field of the Root system of type ['A', 3, 1]
```

dynkin_diagram()
Returns the Dynkin diagram of the root system.

EXAMPLES:

```
sage: R = RootSystem(['A',3])
sage: R.dynkin_diagram()
O---O---O
1   2   3
A3
```

index_set()
EXAMPLES:

```
sage: RootSystem(['A',3]).index_set()
(1, 2, 3)
```

is_finite()
Returns True if self is a finite root system.

EXAMPLES:

```
sage: RootSystem(["A",3]).is_finite()
True
```

```
sage: RootSystem(["A",3,1]).is_finite()
False
```

is_irreducible()

Returns True if self is an irreducible root system.

EXAMPLES:

```
sage: RootSystem(['A', 3]).is_irreducible()
True
sage: RootSystem("A2xB2").is_irreducible()
False
```

root_lattice()

Returns the root lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).root_lattice()
Root lattice of the Root system of type ['A', 3]
```

root_poset(*restricted=False*, *facade=False*)

Returns the (restricted) root poset associated to `self`.

The elements are given by the positive roots (resp. non-simple, positive roots), and $\alpha \leq \beta$ iff $\beta - \alpha$ is a non-negative linear combination of simple roots.

INPUT:

- `restricted` – (default:False) if True, only non-simple roots are considered.
- `facade` – (default:False) passes facade option to the poset generator.

EXAMPLES:

```
sage: Phi = RootSystem(['A',2]).root_poset(); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1], alpha[1] + alpha[2]], [alpha[2], alpha[1] + alpha[2]]]

sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
[[alpha[1] + alpha[2], alpha[1] + alpha[2] + alpha[3]], [alpha[2] + alpha[3], alpha[1] + alp

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
Finite poset containing 4 elements
sage: Phi.cover_relations()
[[alpha[2], alpha[1] + alpha[2]], [alpha[1], alpha[1] + alpha[2]], [alpha[1] + alpha[2], alp
```

root_space(*base_ring=Rational Field*)

Returns the root space associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

weight_lattice(*extended=False*)

Returns the weight lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).weight_lattice()
Weight lattice of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).weight_space(extended = True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]
```

weight_space(*base_ring=Rational Field*, *extended=False*)

Returns the weight space associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).weight_space()
Weight space over the Rational Field of the Root system of type ['A', 3]

sage: RootSystem(['A',3,1]).weight_space(extended = True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]
```

sage.combinat.root_system.root_system.**WeylDim**(*ct*, *coeffs*)

The Weyl Dimension Formula.

INPUT:

- `type` - a Cartan type
- `coeffs` - a list of nonnegative integers

The length of the list must equal the rank type[1]. A dominant weight hwv is constructed by summing the fundamental weights with coefficients from this list. The dimension of the irreducible representation of the semisimple complex Lie algebra with highest weight vector hwv is returned.

EXAMPLES:

For $SO(7)$, the Cartan type is B_3, so:

```
sage: WeylDim(['B',3],[1,0,0]) # standard representation of SO(7)
7
sage: WeylDim(['B',3],[0,1,0]) # exterior square
21
sage: WeylDim(['B',3],[0,0,1]) # spin representation of spin(7)
8
sage: WeylDim(['B',3],[1,0,1]) # sum of the first and third fundamental weights
48
sage: [WeylDim(['F',4],x) for x in [1,0,0,0],[0,1,0,0],[0,0,1,0],[0,0,0,1]]
[52, 1274, 273, 26]
sage: [WeylDim(['E', 6], x) for x in [0, 0, 0, 0, 0, 0], [0, 1, 0, 0, 0, 0], [0, 0, 0, 0, 0, 1],
[1, 78, 27, 351, 351, 351, 27, 650, 351]
```

5.1.211 Root system data for type A

class sage.combinat.root_system.type_A.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: R = RootSystem(["A",3])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3]
sage: TestSuite(e).run()
```

By default, this ambient space uses the barycentric projection for plotting:

```
sage: L = RootSystem(["A",2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(["A",3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)
```

See also:

- sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.ParentM

det(*k=1*)

returns the vector (1, ... ,1) which in the ['A',r] weight lattice, interpreted as a weight of GL(r+1,CC) is the determinant. If the optional parameter k is given, returns (k, ... ,k), the k-th power of the determinant.

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.det(1/2)
(1/2, 1/2, 1/2, 1/2)
```

dimension()

EXAMPLES:

```
sage: e = RootSystem(["A",3]).ambient_space()
sage: e.dimension()
4
```

fundamental_weight(*i*)

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
```

highest_root()

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, -1)
```

negative_roots()

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 1, 0),
```

```
 (0, -1, 0, 1),
 (0, 0, -1, 1)]
```

positive_roots()

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.positive_roots()
[(1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]
```

root(i, j)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.root(0,1)
(1, -1, 0, 0)
```

simple_root(i)

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

classmethod smallest_base_ring(*cartan_type=None*)

Returns the smallest base ring the ambient space can be defined upon

See also:

smallest_base_ring()

EXAMPLES:

```
sage: e = RootSystem(["A",3]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

class sage.combinat.root_system.type_A.**CartanType**(n)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simply_laced, sage.combinat.root_system.cartan_type.CartanType_simple

Cartan Type A_n

See also:

CartanType()

AmbientSpace

alias of AmbientSpace

PieriFactors

alias of PieriFactors_type_A

ascii_art(*label=<function <lambda>>*, *node=None*)
Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['A',0]).ascii_art()
sage: print CartanType(['A',1]).ascii_art()
O
1
sage: print CartanType(['A',3]).ascii_art()
O---O---O
1   2   3
sage: print CartanType(['A',12]).ascii_art()
O---O---O---O---O---O---O---O---O---O---O---O
1   2   3   4   5   6   7   8   9   10  11  12
sage: print CartanType(['A',5]).ascii_art(label = lambda x: x+2)
O---O---O---O---O
3   4   5   6   7
sage: print CartanType(['A',5]).ascii_art(label = lambda x: x-2)
O---O---O---O---O
-1  0   1   2   3
```

coxeter_number()
Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['A',4]).coxeter_number()
5
```

dual_coxeter_number()
Return the dual Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['A',4]).dual_coxeter_number()
5
```

dynkin_diagram()
Returns the Dynkin diagram of type A.

EXAMPLES:

```
sage: a = CartanType(['A',3]).dynkin_diagram()
sage: a
O---O---O
1   2   3
A3
sage: sorted(a.edges())
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1)]
```

TEST:

```
sage: a = DynkinDiagram(['A',1])
sage: a
O
1
A1
sage: a.vertices(), a.edges()
([1], [])
```

5.1.212 Root system data for (untwisted) type A affine

class sage.combinat.root_system.type_A_affine.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

```
sage: ct = CartanType(['A',4,1])
sage: ct
['A', 4, 1]
sage: ct._repr_(compact = True)
'A4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['A', 4]
sage: ct.dual()
['A', 4, 1]

sage: ct = CartanType(['A', 1, 1])
sage: ct.is_simply_laced()
False
sage: ct.dual()
['A', 1, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

PieriFactors

alias of PieriFactors_type_A_affine

ascii_art(*label=<function <lambda>>*, *node=None*)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['A',3,1]).ascii_art()
0
O-------+
|       |
|       |
O---O---O
1   2   3

sage: print CartanType(['A',5,1]).ascii_art(label = lambda x: x+2)
2
O---------------+
|               |
|               |
```

```
O---O---O---O---O
3   4   5   6   7

sage: print CartanType(['A',1,1]).ascii_art()
O<=>O
0   1

sage: print CartanType(['A',1,1]).ascii_art(label = lambda x: x+2)
O<=>O
2   3
```

dual()

Type A_1^1 is self dual despite not being simply laced.

EXAMPLES:

```
sage: CartanType(['A',1,1]).dual()
['A', 1, 1]
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type A.

EXAMPLES:

```
sage: a = CartanType(['A',3,1]).dynkin_diagram()
sage: a
 0
 O-------+
 |       |
 |       |
 O---O---O
 1   2   3
 A3~
sage: sorted(a.edges())
[(0, 1, 1),
 (0, 3, 1),
 (1, 0, 1),
 (1, 2, 1),
 (2, 1, 1),
 (2, 3, 1),
 (3, 0, 1),
 (3, 2, 1)]

sage: a = DynkinDiagram(['A',1,1])
sage: a
O<=>O
0   1
A1~
sage: sorted(a.edges())
[(0, 1, 2), (1, 0, 2)]
```

5.1.213 Root system data for type B

class sage.combinat.root_system.type_B.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: s = e.simple_reflections()

sage: L = RootSystem(['A',3]).coroot_lattice()
sage: e.has_coerce_map_from(L)
True
sage: e(L.simple_root(1))
(1, -1, 0, 0)
```

dimension()

EXAMPLES:

```
sage: e = RootSystem(['B',3]).ambient_space()
sage: e.dimension()
3
```

fundamental_weight(*i*)

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

negative_roots()

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, -1, 0),
 (-1, 0, 1),
 (-1, 0, -1),
 (0, -1, 1),
 (0, -1, -1),
 (-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem(['B',3]).ambient_space().positive_roots()
[(1, -1, 0),
 (1, 1, 0),
 (1, 0, -1),
 (1, 0, 1),
 (0, 1, -1),
 (0, 1, 1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1)]
```

root(*i*, *j*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['B',3]).ambient_space()
sage: e.root(0,1)
(1, -1, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: e = RootSystem(['B',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 1)}
sage: e.positive_roots()
[(1, -1, 0, 0),
(1, 1, 0, 0),
(1, 0, -1, 0),
(1, 0, 1, 0),
(1, 0, 0, -1),
(1, 0, 0, 1),
(0, 1, -1, 0),
(0, 1, 1, 0),
(0, 1, 0, -1),
(0, 1, 0, 1),
(0, 0, 1, -1),
(0, 0, 1, 1),
(1, 0, 0, 0),
(0, 1, 0, 0),
(0, 0, 1, 0),
(0, 0, 0, 1)]
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0), 4: (1/2, 1/2, 1/2, 1/2)}
```

class sage.combinat.root_system.type_B.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

EXAMPLES:

```
sage: ct = CartanType(['B',4])
sage: ct
['B', 4]
sage: ct._repr_(compact = True)
'B4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.affine()
['B', 4, 1]
sage: ct.dual()
['C', 4]

sage: ct = CartanType(['B',1])
sage: ct.is_simply_laced()
True
sage: ct.affine()
['B', 1, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

AmbientSpace
alias of AmbientSpace

PieriFactors
alias of PieriFactors_type_B

ascii_art(*label=<function <lambda>>*, *node=None*)
Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['B',1]).ascii_art()
O
1
sage: print CartanType(['B',2]).ascii_art()
O=>=O
1   2
sage: print CartanType(['B',5]).ascii_art(label = lambda x: x+2)
O---O---O---O=>=O
3   4   5   6   7
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['B',4]).coxeter_number()
8
```

dual()
Types B and C are in duality:

EXAMPLES:

```
sage: CartanType(["C", 3]).dual()
['B', 3]
```

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['B',4]).dual_coxeter_number()
7
```

dynkin_diagram()
Returns a Dynkin diagram for type B.

EXAMPLES:

```
sage: b = CartanType(['B',3]).dynkin_diagram()
sage: b
O---O=>=O
1   2   3
B3
sage: sorted(b.edges())
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

sage: b = CartanType(['B',1]).dynkin_diagram()
sage: b
```

```
O
1
B1
sage: sorted(b.edges())
[]
```

5.1.214 Root system data for type BC affine

class sage.combinat.root_system.type_BC_affine.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_affine

EXAMPLES:

```
sage: ct = CartanType(['BC',4,2])
sage: ct
['BC', 4, 2]
sage: ct._repr_(compact = True)
'BC4~'
sage: ct.dynkin_diagram()
O=<=O---O---O=<=O
0   1   2   3   4
BC4~

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['C', 4]

sage: dual = ct.dual()
sage: dual.dynkin_diagram()
O=>=O---O---O=>=O
0   1   2   3   4
BC4~*

sage: dual.special_node()
0
sage: dual.classical().dynkin_diagram()
O---O---O=>=O
1   2   3   4
B4

sage: CartanType(['BC',1,2]).dynkin_diagram()
  4
O=<=O
0   1
BC1~
```

TESTS:

```
sage: TestSuite(ct).run()
```

ascii_art(*label=<function <lambda>>*, *node=None*)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['BC',2,2]).ascii_art()
O=<=O=<=O
0   1   2
sage: print CartanType(['BC',3,2]).ascii_art()
O=<=O---O=<=O
0   1   2   3
sage: print CartanType(['BC',5,2]).ascii_art(label = lambda x: x+2)
O=<=O---O---O---O=<=O
2   3   4   5   6   7

sage: print CartanType(['BC',1,2]).ascii_art(label = lambda x: x+2)
  4
O=<=O
2   3
```

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: CartanType(['A', 2, 2]).basic_untwisted()
['A', 2]
sage: CartanType(['A', 4, 2]).basic_untwisted()
['A', 4]
sage: CartanType(['BC', 4, 2]).basic_untwisted()
['A', 8]
```

classical()

Returns the classical Cartan type associated with self

sage: CartanType([”BC”, 3, 2]).classical() [’C’, 3]

dynkin_diagram()

Returns the extended Dynkin diagram for affine type BC.

EXAMPLES:

```
sage: c = CartanType(['BC',3,2]).dynkin_diagram()
sage: c
O=<=O---O=<=O
0   1   2   3
BC3~
sage: sorted(c.edges())
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

sage: c = CartanType(["A", 6, 2]).dynkin_diagram() # should be the same as above; did fail a
sage: c
O=<=O---O=<=O
0   1   2   3
BC3~
sage: sorted(c.edges())
```

```
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

sage: c = CartanType(['BC',2,2]).dynkin_diagram()
sage: c
O=<=O=<=O
0   1   2
BC2~
sage: sorted(c.edges())
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 2)]

sage: c = CartanType(['BC',1,2]).dynkin_diagram()
sage: c
  4
O=<=O
0   1
BC1~
sage: sorted(c.edges())
[(0, 1, 1), (1, 0, 4)]
```

5.1.215 Root system data for (untwisted) type B affine

class sage.combinat.root_system.type_B_affine.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

```
sage: ct = CartanType(['B',4,1])
sage: ct
['B', 4, 1]
sage: ct._repr_(compact = True)
'B4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['B', 4]
sage: ct.dual()
['B', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

TESTS:

```
sage: TestSuite(ct).run()
```

PieriFactors

alias of PieriFactors_type_B_affine

ascii_art(*label=<function <lambda>>*, *node=None*)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['B',3,1]).ascii_art()
    O 0
    |
    |
O---O=>=O
1   2   3

sage: print CartanType(['B',5,1]).ascii_art(label = lambda x: x+2)
    O 2
    |
    |
O---O---O---O=>=O
3   4   5   6   7

sage: print CartanType(['B',2,1]).ascii_art(label = lambda x: x+2)
O=>=O=<=O
2   4   3
sage: print CartanType(['B',1,1]).ascii_art(label = lambda x: x+2)
O<=>O
2   3
```

dynkin_diagram()

Return the extended Dynkin diagram for affine type B.

EXAMPLES:

```
sage: b = CartanType(['B',3,1]).dynkin_diagram()
sage: b
    O 0
    |
    |
O---O=>=O
1   2   3
B3~
sage: sorted(b.edges())
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

sage: b = CartanType(['B',2,1]).dynkin_diagram(); b
O=>=O=<=O
0   2   1
B2~
sage: sorted(b.edges())
[(0, 2, 2), (1, 2, 2), (2, 0, 1), (2, 1, 1)]

sage: b = CartanType(['B',1,1]).dynkin_diagram(); b
O<=>O
0   1
B1~
sage: sorted(b.edges())
[(0, 1, 2), (1, 0, 2)]
```

5.1.216 Root system data for type C

class sage.combinat.root_system.type_C.**AmbientSpace**(*root_system*, *base_ring*)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: e = RootSystem(['C',2]).ambient_space(); e
Ambient space of the Root system of type ['C', 2]
```

One cannot construct the ambient lattice because the fundamental coweights have rational coefficients:

```
sage: e.smallest_base_ring()
Rational Field

sage: RootSystem(['B',2]).ambient_space().fundamental_weights()
Finite family {1: (1, 0), 2: (1/2, 1/2)}
```

TESTS:

```
sage: TestSuite(e).run()
```

dimension()
EXAMPLES:

```
sage: e = RootSystem(['C',3]).ambient_space()
sage: e.dimension()
3
```

fundamental_weight(*i*)
EXAMPLES:

```
sage: RootSystem(['C',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1, 1, 1)}
```

negative_roots()
EXAMPLES:

```
sage: RootSystem(['C',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, 0, 1),
 (0, -1, 1),
 (-1, -1, 0),
 (-1, 0, -1),
 (0, -1, -1),
 (-2, 0, 0),
 (0, -2, 0),
 (0, 0, -2)]
```

positive_roots()
EXAMPLES:

```
sage: RootSystem(['C',3]).ambient_space().positive_roots()
[(1, 1, 0),
 (1, 0, 1),
 (0, 1, 1),
 (1, -1, 0),
 (1, 0, -1),
 (0, 1, -1),
 (2, 0, 0),
 (0, 2, 0),
```

```
(0, 0, 2)]
```

root(*i*, *j*, *p1*, *p2*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['C',3]).ambient_space()
sage: e.root(0, 1, 1, 1)
(-1, -1, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: RootSystem(['C',3]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0), 2: (0, 1, -1), 3: (0, 0, 2)}
```

class sage.combinat.root_system.type_C.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

EXAMPLES:

```
sage: ct = CartanType(['C',4])
sage: ct
['C', 4]
sage: ct._repr_(compact = True)
'C4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.affine()
['C', 4, 1]
sage: ct.dual()
['B', 4]

sage: ct = CartanType(['C',1])
sage: ct.is_simply_laced()
True
sage: ct.affine()
['C', 1, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

AmbientSpace

alias of AmbientSpace

ascii_art(*label=<function <lambda>>*, *node=None*)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['C',1]).ascii_art()
O
1
sage: print CartanType(['C',2]).ascii_art()
O=<=O
1   2
sage: print CartanType(['C',3]).ascii_art()
O---O=<=O
1   2   3
sage: print CartanType(['C',5]).ascii_art(label = lambda x: x+2)
O---O---O---O=<=O
3   4   5   6   7
```

coxeter_number()

Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['C',4]).coxeter_number()
8
```

dual()

Types B and C are in duality:

EXAMPLES:

```
sage: CartanType(["C", 3]).dual()
['B', 3]
```

dual_coxeter_number()

Return the dual Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['C',4]).dual_coxeter_number()
5
```

dynkin_diagram()

Returns a Dynkin diagram for type C.

EXAMPLES:

```
sage: c = CartanType(['C',3]).dynkin_diagram()
sage: c
O---O=<=O
1   2   3
C3
sage: e = c.edges(); e.sort(); e
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

 sage: b = CartanType(['C',1]).dynkin_diagram()
 sage: b
 O
 1
 C1
 sage: sorted(b.edges())
 []
```

5.1.217 Root system data for (untwisted) type C affine

class sage.combinat.root_system.type_C_affine.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

```
sage: ct = CartanType(['C',4,1])
sage: ct
['C', 4, 1]
sage: ct._repr_(compact = True)
'C4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['C', 4]
sage: ct.dual()
['C', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

TESTS:

```
sage: TestSuite(ct).run()
```

PieriFactors

alias of PieriFactors_type_C_affine

ascii_art(*label=<function <lambda>>*, *node=None*)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['C',5,1]).ascii_art(label = lambda x: x+2)
O=>=O---O---O---O=<=O
2   3   4   5   6   7

sage: print CartanType(['C',3,1]).ascii_art()
O=>=O---O=<=O
0   1   2   3

sage: print CartanType(['C',2,1]).ascii_art()
O=>=O=<=O
0   1   2

sage: print CartanType(['C',1,1]).ascii_art()
O<=>O
0   1
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type C.

EXAMPLES:

```
sage: c = CartanType(['C',3,1]).dynkin_diagram()
sage: c
 O=>=O---O=<=O
 0   1   2   3
 C3~
sage: sorted(c.edges())
[(0, 1, 2), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
```

5.1.218 Root system data for type D

class sage.combinat.root_system.type_D.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: s = e.simple_reflections()

sage: L = RootSystem(['A',3]).coroot_lattice()
sage: e.has_coerce_map_from(L)
True
sage: e(L.simple_root(1))
(1, -1, 0, 0)
```

dimension()

EXAMPLES:

```
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.dimension()
3
```

fundamental_weight(*i*)

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1/2, 1/2, 1/2, -1/2), 4: (1/2, 1/2, 1/2
```

negative_roots()

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (0, -1, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 0, 1),
 (0, 0, -1, 1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
 (0, -1, -1, 0),
 (-1, 0, 0, -1),
 (0, -1, 0, -1),
 (0, 0, -1, -1)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().positive_roots()
[(1, 1, 0, 0),
 (1, 0, 1, 0),
 (0, 1, 1, 0),
 (1, 0, 0, 1),
 (0, 1, 0, 1),
 (0, 0, 1, 1),
 (1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]
```

root(*i*, *j*, *p1*, *p2*)

Note that indexing starts at 0.

EXAMPLES:

```
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.root(0, 1, 1, 1)
(-1, -1, 0)
sage: e.root(0, 0, 1, 1)
(-1, 0, 0)
```

simple_root(*i*)

EXAMPLES:

```
sage: RootSystem(['D',4]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 1, 1)}
```

class sage.combinat.root_system.type_D.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simply_laced

EXAMPLES:

```
sage: ct = CartanType(['D',4])
sage: ct
['D', 4]
sage: ct._repr_(compact = True)
'D4'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.dual()
['D', 4]
sage: ct.affine()
['D', 4, 1]

sage: ct = CartanType(['D',2])
sage: ct.is_irreducible()
False
```

```
sage: ct.dual()
['D', 2]
sage: ct.affine()
Traceback (most recent call last):
...
ValueError: ['D', 2, 1] is not a valid Cartan type
```

TESTS:

```
sage: TestSuite(ct).run()
```

AmbientSpace
alias of AmbientSpace

ascii_art(*label=<function <lambda>>*, *node=None*)
Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['D',3]).ascii_art()
O 3
|
|
O---O
1   2
sage: print CartanType(['D',4]).ascii_art()
    O 4
    |
    |
O---O---O
1   2   3
sage: print CartanType(['D',4]).ascii_art(label = lambda x: x+2)
    O 6
    |
    |
O---O---O
3   4   5
sage: print CartanType(['D',6]).ascii_art(label = lambda x: x+2)
            O 8
            |
            |
O---O---O---O---O
3   4   5   6   7
```

coxeter_number()
Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['D',4]).coxeter_number()
6
```

dual_coxeter_number()
Return the dual Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['D',4]).dual_coxeter_number()
6
```

dynkin_diagram()
Returns a Dynkin diagram for type D.

EXAMPLES:

```
sage: d = CartanType(['D',5]).dynkin_diagram(); d
        O 5
        |
        |
O---O---O---O
1   2   3   4
D5
sage: sorted(d.edges())
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1), (3, 4, 1), (3, 5, 1), (4, 3, 1), (5, 3, 1)]

sage: d = CartanType(['D',4]).dynkin_diagram(); d
    O 4
    |
    |
O---O---O
1   2   3
D4
sage: sorted(d.edges())
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (2, 4, 1), (3, 2, 1), (4, 2, 1)]

sage: d = CartanType(['D',3]).dynkin_diagram(); d
O 3
|
|
O---O
1   2
D3
sage: sorted(d.edges())
[(1, 2, 1), (1, 3, 1), (2, 1, 1), (3, 1, 1)]

sage: d = CartanType(['D',2]).dynkin_diagram(); d
O   O
1   2
D2
sage: sorted(d.edges())
[]
```

is_atomic()
Implements `CartanType_abstract.is_atomic()`

D_2 is atomic, like all D_n, despite being non irreducible.

EXAMPLES:

```
sage: CartanType(["D",2]).is_atomic()
True
sage: CartanType(["D",2]).is_irreducible()
False
```

5.1.219 Root system data for (untwisted) type D affine

class sage.combinat.root_system.type_D_affine.**CartanType**(*n*)
Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine,

sage.combinat.root_system.cartan_type.CartanType_simply_laced

EXAMPLES:

```
sage: ct = CartanType(['D',4,1])
sage: ct
['D', 4, 1]
sage: ct._repr_(compact = True)
'D4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['D', 4]
sage: ct.dual()
['D', 4, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

PieriFactors

alias of PieriFactors_type_D_affine

ascii_art(*label=<function <lambda>>*, *node=None*)

Return an ascii art representation of the extended Dynkin diagram.

TESTS:

```
sage: print CartanType(['D',6,1]).ascii_art(label = lambda x: x+2)
  2 O       O 8
    |       |
    |       |
O---O---O---O---O
3   4   5   6   7

sage: print CartanType(['D',4,1]).ascii_art(label = lambda x: x+2)
    O 6
    |
    |
O---O---O
3   |4  5
    |
    O 2

sage: print CartanType(['D',3,1]).ascii_art(label = lambda x: x+2)
2
O-------+
|       |
|       |
O---O---O
```

```
5   3   4
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type D.

EXAMPLES:

```
sage: d = CartanType(['D', 6, 1]).dynkin_diagram()
sage: d
   0 O       O 6
     |       |
     |       |
 O---O---O---O---O
 1   2   3   4   5
 D6~
sage: sorted(d.edges())
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 1),
 (3, 2, 1), (3, 4, 1), (4, 3, 1), (4, 5, 1), (4, 6, 1), (5, 4, 1), (6, 4, 1)]

sage: d = CartanType(['D', 4, 1]).dynkin_diagram()
sage: d
    O 4
    |
    |
O---O---O
1   |2  3
    |
    O 0
D4~
sage: sorted(d.edges())
[(0, 2, 1),
 (1, 2, 1),
 (2, 0, 1),
 (2, 1, 1),
 (2, 3, 1),
 (2, 4, 1),
 (3, 2, 1),
 (4, 2, 1)]

sage: d = CartanType(['D', 3, 1]).dynkin_diagram()
sage: d
0
O-------+
|       |
|       |
O---O---O
3   1   2
D3~
sage: sorted(d.edges())
[(0, 2, 1), (0, 3, 1), (1, 2, 1), (1, 3, 1), (2, 0, 1), (2, 1, 1), (3, 0, 1), (3, 1, 1)]
```

5.1.220 Root system data for type E

class sage.combinat.root_system.type_E.**AmbientSpace**(*root_system*, *baseRing*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

The lattice behind E6, E7, or E8. The computations are based on Bourbaki, Groupes et Algebres de Lie, Ch.

4,5,6 (planche V-VII).

dimension()

EXAMPLES:

```
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.dimension()
8
```

fundamental_weights()

EXAMPLES:

```
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (0, 0, 0, 0, 0, -2/3, -2/3, 2/3), 2: (1/2, 1/2, 1/2, 1/2, 1/2, -1/2, -1/2,
```

negative_roots()

The negative negative roots.

EXAMPLES:

```
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.negative_roots()
[(-1, -1, 0, 0, 0, 0, 0, 0),
 (-1, 0, -1, 0, 0, 0, 0, 0),
 (-1, 0, 0, -1, 0, 0, 0, 0),
 (-1, 0, 0, 0, -1, 0, 0, 0),
 (0, -1, -1, 0, 0, 0, 0, 0),
 (0, -1, 0, -1, 0, 0, 0, 0),
 (0, -1, 0, 0, -1, 0, 0, 0),
 (0, 0, -1, -1, 0, 0, 0, 0),
 (0, 0, -1, 0, -1, 0, 0, 0),
 (0, 0, 0, -1, -1, 0, 0, 0),
 (1, -1, 0, 0, 0, 0, 0, 0),
 (1, 0, -1, 0, 0, 0, 0, 0),
 (1, 0, 0, -1, 0, 0, 0, 0),
 (1, 0, 0, 0, -1, 0, 0, 0),
 (0, 1, -1, 0, 0, 0, 0, 0),
 (0, 1, 0, -1, 0, 0, 0, 0),
 (0, 1, 0, 0, -1, 0, 0, 0),
 (0, 0, 1, -1, 0, 0, 0, 0),
 (0, 0, 1, 0, -1, 0, 0, 0),
 (0, 0, 0, 1, -1, 0, 0, 0),
 (-1/2, -1/2, -1/2, -1/2, -1/2, 1/2, 1/2, -1/2),
 (-1/2, -1/2, -1/2, 1/2, 1/2, 1/2, 1/2, -1/2),
 (-1/2, -1/2, 1/2, -1/2, 1/2, 1/2, 1/2, -1/2),
 (-1/2, -1/2, 1/2, 1/2, -1/2, 1/2, 1/2, -1/2),
 (-1/2, 1/2, -1/2, -1/2, 1/2, 1/2, 1/2, -1/2),
 (-1/2, 1/2, -1/2, 1/2, -1/2, 1/2, 1/2, -1/2),
 (-1/2, 1/2, 1/2, -1/2, -1/2, 1/2, 1/2, -1/2),
 (-1/2, 1/2, 1/2, 1/2, 1/2, 1/2, 1/2, -1/2),
 (1/2, -1/2, -1/2, -1/2, 1/2, 1/2, 1/2, -1/2),
 (1/2, -1/2, -1/2, 1/2, -1/2, 1/2, 1/2, -1/2),
 (1/2, -1/2, 1/2, -1/2, -1/2, 1/2, 1/2, -1/2),
 (1/2, -1/2, 1/2, 1/2, 1/2, 1/2, 1/2, -1/2),
 (1/2, 1/2, -1/2, -1/2, -1/2, 1/2, 1/2, -1/2),
 (1/2, 1/2, -1/2, 1/2, 1/2, 1/2, 1/2, -1/2),
 (1/2, 1/2, 1/2, -1/2, 1/2, 1/2, 1/2, -1/2),
 (1/2, 1/2, 1/2, 1/2, -1/2, 1/2, 1/2, -1/2)]
```

positive_roots()

These are the roots positive w.r. to lexicographic ordering of the basis elements (e1<...<e4).

EXAMPLES:

```
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.positive_roots()
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 0, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (1, 0, 0, 0, 1, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (-1, 1, 0, 0, 0, 0, 0, 0),
 (-1, 0, 1, 0, 0, 0, 0, 0),
 (-1, 0, 0, 1, 0, 0, 0, 0),
 (-1, 0, 0, 0, 1, 0, 0, 0),
 (0, -1, 1, 0, 0, 0, 0, 0),
 (0, -1, 0, 1, 0, 0, 0, 0),
 (0, -1, 0, 0, 1, 0, 0, 0),
 (0, 0, -1, 1, 0, 0, 0, 0),
 (0, 0, -1, 0, 1, 0, 0, 0),
 (0, 0, 0, -1, 1, 0, 0, 0),
 (1/2, 1/2, 1/2, 1/2, 1/2, -1/2, -1/2, 1/2),
 (1/2, 1/2, 1/2, -1/2, -1/2, -1/2, -1/2, 1/2),
 (1/2, 1/2, -1/2, 1/2, -1/2, -1/2, -1/2, 1/2),
 (1/2, 1/2, -1/2, -1/2, 1/2, -1/2, -1/2, 1/2),
 (1/2, -1/2, 1/2, 1/2, -1/2, -1/2, -1/2, 1/2),
 (1/2, -1/2, 1/2, -1/2, 1/2, -1/2, -1/2, 1/2),
 (1/2, -1/2, -1/2, 1/2, 1/2, -1/2, -1/2, 1/2),
 (1/2, -1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2),
 (-1/2, 1/2, 1/2, 1/2, -1/2, -1/2, -1/2, 1/2),
 (-1/2, 1/2, 1/2, -1/2, 1/2, -1/2, -1/2, 1/2),
 (-1/2, 1/2, -1/2, 1/2, 1/2, -1/2, -1/2, 1/2),
 (-1/2, 1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2),
 (-1/2, -1/2, 1/2, 1/2, 1/2, -1/2, -1/2, 1/2),
 (-1/2, -1/2, 1/2, -1/2, -1/2, -1/2, -1/2, 1/2),
 (-1/2, -1/2, -1/2, 1/2, -1/2, -1/2, -1/2, 1/2),

 (1/2, 1/2, 1/2, 1/2, -1/2, 1/2, 1/2, -1/2),
 (1/2, 1/2, 1/2, 1/2, 1/2, -1/2, 1/2, -1/2),
 (1/2, 1/2, 1/2, 1/2, 1/2, 1/2, -1/2, -1/2)]
sage: e.rho()
(0, 1, 2, 3, 4, 5, 6, 23)
```

root(*i1*, *i2=None*, *i3=None*, *i4=None*, *i5=None*, *i6=None*, *i7=None*, *i8=None*, *p1=0*, *p2=0*, *p3=0*, *p4=0*, *p5=0*, *p6=0*, *p7=0*, *p8=0*)

Compute an element of the underlying lattice, using the specified elements of the standard basis, with signs dictated by the corresponding 'pi' arguments. We rely on the caller to provide the correct arguments. This is typically used to generate roots, although the generated elements need not be roots themselves. We

assume that if one of the indices is not given, the rest are not as well. This should work for E6, E7, E8.

EXAMPLES:

```
sage: e = RootSystem(['E',6]).ambient_space()
sage: [ e.root(i, j, p3=1) for i in xrange(e.n) for j in xrange(i+1, e.n) ]
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 0, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (1, 0, 0, 0, 1, 0, 0, 0),
 (1, 0, 0, 0, 0, 1, 0, 0),
 (1, 0, 0, 0, 0, 0, 1, 0),
 (1, 0, 0, 0, 0, 0, 0, 1),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 1, 0, 0, 0, 1, 0, 0),
 (0, 1, 0, 0, 0, 0, 1, 0),
 (0, 1, 0, 0, 0, 0, 0, 1),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0, 1, 0, 0),
 (0, 0, 1, 0, 0, 0, 1, 0),
 (0, 0, 1, 0, 0, 0, 0, 1),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (0, 0, 0, 1, 0, 1, 0, 0),
 (0, 0, 0, 1, 0, 0, 1, 0),
 (0, 0, 0, 1, 0, 0, 0, 1),
 (0, 0, 0, 0, 1, 1, 0, 0),
 (0, 0, 0, 0, 1, 0, 1, 0),
 (0, 0, 0, 0, 1, 0, 0, 1),
 (0, 0, 0, 0, 0, 1, 1, 0),
 (0, 0, 0, 0, 0, 1, 0, 1),
 (0, 0, 0, 0, 0, 0, 1, 1)]
```

simple_root(*i*)

There are computed as what Bourbaki calls the Base: a1 = e2-e3, a2 = e3-e4, a3 = e4, a4 = 1/2*(e1-e2-e3-e4)

EXAMPLES:

```
sage: LE6 = RootSystem(['E',6]).ambient_space()
sage: LE6.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2), 2: (1, 1, 0, 0, 0, 0, 0, 0
```

class sage.combinat.root_system.type_E.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_simply_laced

EXAMPLES:

```
sage: ct = CartanType(['E',6])
sage: ct
['E', 6]
sage: ct._repr_(compact = True)
'E6'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
```

```
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.affine()
['E', 6, 1]
sage: ct.dual()
['E', 6]
```

TESTS:

```
sage: TestSuite(ct).run()
```

AmbientSpace
alias of AmbientSpace

ascii_art(*label=<function <lambda>>*, *node=None*)
Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['E',6]).ascii_art(label = lambda x: x+2)
        O 4
        |
        |
O---O---O---O---O
3   5   6   7   8
sage: print CartanType(['E',7]).ascii_art(label = lambda x: x+2)
        O 4
        |
        |
O---O---O---O---O---O
3   5   6   7   8   9
sage: print CartanType(['E',8]).ascii_art(label = lambda x: x+1)
        O 3
        |
        |
O---O---O---O---O---O---O
2   4   5   6   7   8   9
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['E',6]).coxeter_number()
12
sage: CartanType(['E',7]).coxeter_number()
18
sage: CartanType(['E',8]).coxeter_number()
30
```

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['E',6]).dual_coxeter_number()
12
sage: CartanType(['E',7]).dual_coxeter_number()
18
sage: CartanType(['E',8]).dual_coxeter_number()
30
```

dynkin_diagram()

Returns a Dynkin diagram for type E.

EXAMPLES:

```
sage: e = CartanType(['E',6]).dynkin_diagram()
sage: e
        O 2
        |
        |
O---O---O---O---O
1   3   4   5   6
E6
sage: sorted(e.edges())
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1), (4, 3, 1), (4, 5, 1), (5, 4, 1), (5,
sage: e = CartanType(['E',7]).dynkin_diagram()
sage: e
        O 2
        |
        |
O---O---O---O---O---O
1   3   4   5   6   7
E7
sage: sorted(e.edges())
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1),
 (6, 7, 1), (7, 6, 1)]
sage: e = CartanType(['E',8]).dynkin_diagram()
sage: e
        O 2
        |
        |
O---O---O---O---O---O---O
1   3   4   5   6   7   8
E8
sage: sorted(e.edges())
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1),
 (6, 7, 1), (7, 6, 1), (7, 8, 1), (8, 7, 1)]
```

5.1.221 Root system data for (untwisted) type E affine

class sage.combinat.root_system.type_E_affine.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine, sage.combinat.root_system.cartan_type.CartanType_simply_laced

EXAMPLES:

```
sage: ct = CartanType(['E',6,1])
sage: ct
['E', 6, 1]
```

```
sage: ct._repr_(compact = True)
'E6~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['E', 6]
sage: ct.dual()
['E', 6, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

ascii_art(*label=<function <lambda>>*, *node=None*)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['E',6,1]).ascii_art(label = lambda x: x+2)
        O 2
        |
        |
        O 4
        |
        |
O---O---O---O---O---O
3   5   6   7   8   9
sage: print CartanType(['E',7,1]).ascii_art(label = lambda x: x+2)
            O 4
            |
            |
O---O---O---O---O---O---O---O
2   3   5   6   7   8   9   10
sage: print CartanType(['E',8,1]).ascii_art(label = lambda x: x-3)
        O -1
        |
        |
O---O---O---O---O---O---O---O---O
-2  0   1   2   3   4   5   6   -3
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type E.

EXAMPLES:

```
sage: e = CartanType(['E', 6, 1]).dynkin_diagram()
sage: e
        O 0
        |
```

```
        |
        O 2
        |
        |
O---O---O---O---O
1   3   4   5   6
E6~
sage: sorted(e.edges())
[(0, 2, 1),
 (1, 3, 1),
 (2, 0, 1),
 (2, 4, 1),
 (3, 1, 1),
 (3, 4, 1),
 (4, 2, 1),
 (4, 3, 1),
 (4, 5, 1),
 (5, 4, 1),
 (5, 6, 1),
 (6, 5, 1)]

sage: e = CartanType(['E', 7, 1]).dynkin_diagram()
sage: e
            O 2
            |
            |
O---O---O---O---O---O---O
0   1   3   4   5   6   7
E7~
sage: sorted(e.edges())
[(0, 1, 1), (1, 0, 1), (1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1),
 (4, 2, 1), (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 1), (7, 6, 1)]
sage: e = CartanType(['E', 8, 1]).dynkin_diagram()
sage: e
        O 2
        |
        |
O---O---O---O---O---O---O---O
1   3   4   5   6   7   8   0
E8~
sage: sorted(e.edges())
[(0, 8, 1), (1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1),
 (4, 2, 1), (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 1), (7, 6, 1), (7, 8, 1), (8, 0, 1), (8, 7, 1)]
```

5.1.222 Root system data for type F

class sage.combinat.root_system.type_F.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

The lattice behind F_4. The computations are based on Bourbaki, Groupes et Algebres de Lie, Ch. 4,5,6 (planche VIII).

dimension()

Return the dimension of self.

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.dimension()
4
```

fundamental_weights()

Return the fundamental weights of `self`.

EXAMPLES:

```
sage: e =  RootSystem(['F',4]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
```

negative_roots()

Return the negative roots.

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.negative_roots()
[(-1, 0, 0, 0),
(0, -1, 0, 0),
(0, 0, -1, 0),
(0, 0, 0, -1),
(-1, -1, 0, 0),
(-1, 0, -1, 0),
(-1, 0, 0, -1),
(0, -1, -1, 0),
(0, -1, 0, -1),
(0, 0, -1, -1),
(-1, 1, 0, 0),
(-1, 0, 1, 0),
(-1, 0, 0, 1),
(0, -1, 1, 0),
(0, -1, 0, 1),
(0, 0, -1, 1),
(-1/2, -1/2, -1/2, -1/2),
(-1/2, -1/2, -1/2, 1/2),
(-1/2, -1/2, 1/2, -1/2),
(-1/2, -1/2, 1/2, 1/2),
(-1/2, 1/2, -1/2, -1/2),
(-1/2, 1/2, -1/2, 1/2),
(-1/2, 1/2, 1/2, -1/2),
(-1/2, 1/2, 1/2, 1/2)]
```

positive_roots()

Return the positive roots.

These are the roots which are positive with respect to the lexicographic ordering of the basis elements ($\epsilon_1 < \epsilon_2 < \epsilon_3 < \epsilon_4$).

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.positive_roots()
[(1, 0, 0, 0),
(0, 1, 0, 0),
(0, 0, 1, 0),
(0, 0, 0, 1),
(1, 1, 0, 0),
```

```
(1, 0, 1, 0),
(1, 0, 0, 1),
(0, 1, 1, 0),
(0, 1, 0, 1),
(0, 0, 1, 1),
(1, -1, 0, 0),
(1, 0, -1, 0),
(1, 0, 0, -1),
(0, 1, -1, 0),
(0, 1, 0, -1),
(0, 0, 1, -1),
(1/2, 1/2, 1/2, 1/2),
(1/2, 1/2, 1/2, -1/2),
(1/2, 1/2, -1/2, 1/2),
(1/2, 1/2, -1/2, -1/2),
(1/2, -1/2, 1/2, 1/2),
(1/2, -1/2, 1/2, -1/2),
(1/2, -1/2, -1/2, 1/2),
(1/2, -1/2, -1/2, -1/2)]
sage: e.rho()
(11/2, 5/2, 3/2, 1/2)
```

root (*i*, *j=None*, *k=None*, *l=None*, *p1=0*, *p2=0*, *p3=0*, *p4=0*)

Compute a root from base elements of the underlying lattice. The arguments specify the basis elements and the signs. Sadly, the base elements are indexed zero-based. We assume that if one of the indices is not given, the rest are not as well.

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: [ e.root(i,j,p2=1) for i in xrange(e.n) for j in xrange(i+1,e.n) ]
[(1, -1, 0, 0), (1, 0, -1, 0), (1, 0, 0, -1), (0, 1, -1, 0), (0, 1, 0, -1), (0, 0, 1, -1)]
```

simple_root (*i*)

Return the i-th simple root.

It is computed according to what Bourbaki calls the Base:

$$\alpha_1 = \epsilon_2 - \epsilon_3, \alpha_2 = \epsilon_3 - \epsilon_4, \alpha_3 = \epsilon_4, \alpha_4 = \frac{1}{2}(\epsilon_1 - \epsilon_2 - \epsilon_3 - \epsilon_4).$$

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/
```

class sage.combinat.root_system.type_F.**CartanType**

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

EXAMPLES:

```
sage: ct = CartanType(['F',4])
sage: ct
['F', 4]
sage: ct._repr_(compact = True)
'F4'
```

```
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

AmbientSpace
alias of AmbientSpace

ascii_art(*label=<function <lambda>>*, *node=None*)
Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['F',4]).ascii_art(label = lambda x: x+2)
O---O=>=O---O
3   4   5   6
sage: print CartanType(['F',4]).ascii_art(label = lambda x: x-2)
O---O=>=O---O
-1  0   1   2
```

coxeter_number()
Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['F',4]).coxeter_number()
12
```

dual()
Return the dual Cartan type.

This uses that F_4 is self-dual up to relabelling.

EXAMPLES:

```
sage: F4 = CartanType(['F',4])
sage: F4.dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}

sage: F4.dynkin_diagram()
O---O=>=O---O
1   2   3   4
F4
sage: F4.dual().dynkin_diagram()
O---O=>=O---O
4   3   2   1
F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

dual_coxeter_number()
Return the dual Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['F',4]).dual_coxeter_number()
9
```

dynkin_diagram()
Returns a Dynkin diagram for type F.

EXAMPLES:

```
sage: f = CartanType(['F',4]).dynkin_diagram()
sage: f
O---O=>=O---O
1   2   3   4
F4
sage: sorted(f.edges())
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

5.1.223 Root system data for (untwisted) type F affine

class sage.combinat.root_system.type_F_affine.**CartanType**
Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

```
sage: ct = CartanType(['F',4,1])
sage: ct
['F', 4, 1]
sage: ct._repr_(compact = True)
'F4~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['F', 4]
sage: ct.dual()
['F', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

TESTS:

```
sage: TestSuite(ct).run()
```

ascii_art(*label=<function <lambda>>*, *node=None*)
Returns a ascii art representation of the extended Dynkin diagram

EXAMPLES:

```
sage: print CartanType(['F',4,1]).ascii_art(label = lambda x: x+2)
O---O---O=>=O---O
2   3   4   5   6
```

dynkin_diagram()

Returns the extended Dynkin diagram for affine type F.

EXAMPLES:

```
sage: f = CartanType(['F', 4, 1]).dynkin_diagram()
sage: f
O---O---O=>=O---O
0   1   2   3   4
F4~
sage: sorted(f.edges())
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

5.1.224 Root system data for type G

class sage.combinat.root_system.type_G.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: e = RootSystem(['G',2]).ambient_space(); e
Ambient space of the Root system of type ['G', 2]
```

One can not construct the ambient lattice because the simple coroots have rational coefficients:

```
sage: e.simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
sage: e.smallest_base_ring()
Rational Field
```

TESTS:

```
sage: TestSuite(e).run()
sage: [WeylDim(['G',2],[a,b]) for a,b in [[0,0], [1,0], [0,1], [1,1]]] # indirect doctest
[1, 7, 14, 64]
```

By default, this ambient space uses the barycentric projection for plotting:

```
sage: L = RootSystem(["G",2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(["A",3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)
```

See also:

- sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.ParentM

dimension()

EXAMPLES:

```
sage: e = RootSystem(['G',2]).ambient_space()
sage: e.dimension()
3
```

fundamental_weights()

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

negative_roots()

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().negative_roots()
[(0, -1, 1), (-1, 2, -1), (-1, 1, 0), (-1, 0, 1), (-1, -1, 2), (-2, 1, 1)]
```

positive_roots()

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

simple_root(*i*)

EXAMPLES:

```
sage: CartanType(['G',2]).root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

class sage.combinat.root_system.type_G.**CartanType**

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple, sage.combinat.root_system.cartan_type.CartanType_crystallographic

EXAMPLES:

```
sage: ct = CartanType(['G',2])
sage: ct
['G', 2]
sage: ct._repr_(compact = True)
'G2'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.dual()
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1]
```

TESTS:

```
sage: TestSuite(ct).run()
```

AmbientSpace
alias of AmbientSpace

ascii_art(*label=<function <lambda>>*, *node=None*)
Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```
sage: print CartanType(['G',2]).ascii_art(label=lambda x: x+2)
  3
O=<=O
3   4
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['G',2]).coxeter_number()
6
```

dual()
Return the dual Cartan type.

This uses that G_2 is self-dual up to relabelling.

EXAMPLES:

```
sage: G2 = CartanType(['G',2])
sage: G2.dual()
['G', 2] relabelled by {1: 2, 2: 1}

sage: G2.dynkin_diagram()
  3
O=<=O
1   2
G2
sage: G2.dual().dynkin_diagram()
  3
O=<=O
2   1
G2 relabelled by {1: 2, 2: 1}
```

dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['G',2]).dual_coxeter_number()
4
```

dynkin_diagram()
Returns a Dynkin diagram for type G.

EXAMPLES:

```
sage: g = CartanType(['G',2]).dynkin_diagram()
sage: g
  3
O=<=O
```

```
1   2
G2
sage: sorted(g.edges())
[(1, 2, 1), (2, 1, 3)]
```

5.1.225 Root system data for (untwisted) type G affine

class sage.combinat.root_system.type_G_affine.**CartanType**

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_untwisted_affine

EXAMPLES:

```
sage: ct = CartanType(['G',2,1])
sage: ct
['G', 2, 1]
sage: ct._repr_(compact = True)
'G2~'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['G', 2]
sage: ct.dual()
['G', 2, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

TESTS:

```
sage: TestSuite(ct).run()
```

ascii_art(*label=<function <lambda>>*, *node=None*)

Returns an ascii art representation of the Dynkin diagram

EXAMPLES:

```
sage: print CartanType(['G',2,1]).ascii_art(label = lambda x: x+2)
  3
O=<=O---O
3   4   2
```

dynkin_diagram()

Returns the extended Dynkin diagram for type G.

EXAMPLES:

```
sage: g = CartanType(['G',2,1]).dynkin_diagram()
sage: g
  3
```

```
O=<=O---O
1   2   0
G2~
sage: sorted(g.edges())
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 3)]
```

5.1.226 Root system data for type H

class sage.combinat.root_system.type_H.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple

EXAMPLES:

```
sage: ct = CartanType(['H',3])
sage: ct
['H', 3]
sage: ct._repr_(compact = True)
'H3'
sage: ct.rank()
3

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False
```

TESTS:

```
sage: TestSuite(ct).run()
```

coxeter_diagram()

Returns a Coxeter diagram for type H.

EXAMPLES:

```
sage: ct = CartanType(['H',3])
sage: ct.coxeter_diagram()
Graph on 3 vertices
sage: sorted(ct.coxeter_diagram().edges())
[(1, 2, 3), (2, 3, 5)]
sage: ct.coxeter_matrix()
[1 3 2]
[3 1 5]
[2 5 1]

sage: ct = CartanType(['H',4])
sage: ct.coxeter_diagram()
Graph on 4 vertices
sage: sorted(ct.coxeter_diagram().edges())
[(1, 2, 3), (2, 3, 3), (3, 4, 5)]
sage: ct.coxeter_matrix()
```

```
[1 3 2 2]
[3 1 3 2]
[2 3 1 5]
[2 2 5 1]
```

coxeter_number()

Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['H',3]).coxeter_number()
10
sage: CartanType(['H',4]).coxeter_number()
30
```

5.1.227 Root system data for type I

class sage.combinat.root_system.type_I.**CartanType**(*n*)

Bases: sage.combinat.root_system.cartan_type.CartanType_standard_finite, sage.combinat.root_system.cartan_type.CartanType_simple

EXAMPLES:

```
sage: ct = CartanType(['I',5])
sage: ct
['I', 5]
sage: ct._repr_(compact = True)
'I5'
sage: ct.rank()
2
sage: ct.index_set()
(1, 2)

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False
```

TESTS:

```
sage: TestSuite(ct).run()
```

coxeter_diagram()

Returns the Coxeter matrix for this type.

EXAMPLES:

```
sage: ct = CartanType(['I', 4])
sage: ct.coxeter_diagram()
Graph on 2 vertices
sage: ct.coxeter_diagram().edges()
[(1, 2, 4)]
sage: ct.coxeter_matrix()
```

```
[1 4]
[4 1]
```

coxeter_number()
Return the Coxeter number associated with `self`.

EXAMPLES:

```
sage: CartanType(['I',3]).coxeter_number()
3
sage: CartanType(['I',12]).coxeter_number()
12
```

index_set()
Type I_p is of rank 2

EXAMPLES:

```
sage: CartanType(['I', 5]).index_set()
(1, 2)
```

rank()
Type I_p is of rank 2

EXAMPLES:

```
sage: CartanType(['I', 5]).rank()
2
```

5.1.228 Root system data for affine Cartan types

class sage.combinat.root_system.type_affine.**AmbientSpace**(*root_system*, *base_ring*)
Bases: sage.combinat.free_module.CombinatorialFreeModule

Ambient space for affine types.

This is constructed from the data in the corresponding classical ambient space. Namely, this space is obtained by adding two elements δ and $\delta^\vee$ to the basis of the classical ambient space, and by endowing it with the canonical scalar product.

The coefficient of an element in $\delta^\vee$, thus its scalar product with $\delta^\vee$ gives its level, and dualy for the colevel. The canonical projection onto the classical ambient space (by killing δ and $\delta^\vee$) maps the simple roots (except α_0) onto the corresponding classical simple roots, and similarly for the coroots, fundamental weights, ... Altogether, this uniquely determines the embedding of the root, coroot, weight, and coweight lattices. See `simple_root()` and `fundamental_weight()` for the details.

Warning: In type BC, the null root is in fact:

```
sage: R = RootSystem(["BC",3,2]).ambient_space()
sage: R.null_root()
2*e['delta']
```

Warning: In the literature one often considers a larger affine ambient space obtained from the classical ambient space by adding four dimensions, namely for the fundamental weight Λ_0 the fundamental coweight $\Lambda_0^\vee$, the null root δ, and the null coroot c (aka central element). In this larger ambient space, the scalar product is degenerate: $\langle \delta, \delta \rangle = 0$ and similarly for the null coroot.
In the current implementation, Λ_0 and the null coroot are identified:
sage: L = RootSystem(["A",3,1]).ambient_space() sage: Lambda = L.fundamental_weights()
sage: Lambda[0] e['deltacheck'] sage: L.null_coroot() e['deltacheck']
Therefore the scalar product of the null coroot with itself differs from the larger ambient space:

```
sage: L.null_coroot().scalar(L.null_coroot())
1
```

In general, scalar products between two elements that do not live on "opposite sides" won't necessarily match.

EXAMPLES:

```
sage: R = RootSystem(["A",3,1])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3, 1]
sage: TestSuite(e).run()
```

Systematic checks on all affine types:

```
sage: for ct in CartanType.samples(affine=True, crystallographic=True):
...       if ct.classical().root_system().ambient_space() is not None:
...           print ct
...           L = ct.root_system().ambient_space()
...           assert L
...           TestSuite(L).run()
['A', 1, 1]
['A', 5, 1]
['B', 1, 1]
['B', 5, 1]
['C', 1, 1]
['C', 5, 1]
['D', 3, 1]
['D', 5, 1]
['E', 6, 1]
['E', 7, 1]
['E', 8, 1]
['F', 4, 1]
['G', 2, 1]
['BC', 1, 2]
['BC', 5, 2]
['B', 5, 1]^*
['C', 4, 1]^*
['F', 4, 1]^*
['G', 2, 1]^*
['BC', 1, 2]^*
['BC', 5, 2]^*
```

class **Element**(M, x)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

associated_coroot()

Return the coroot associated to `self`.

INPUT:

- `self` – a root

EXAMPLES:

```
sage: alpha = RootSystem(['C',2,1]).ambient_space().simple_roots()
sage: alpha
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: alpha[0].associated_coroot()
-e[0] + e['deltacheck']
sage: alpha[1].associated_coroot()
e[0] - e[1]
sage: alpha[2].associated_coroot()
e[1]
```

inner_product(*other*)

Implement the canonical inner product of `self` with `other`.

EXAMPLES:

```
sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17
```

`scalar()` is an alias for this method:

```
sage: x.scalar(x)
17
```

Todo

Lift to CombinatorialFreeModule.Element as canonical_inner_product

---

scalar(*other*)

Implement the canonical inner product of `self` with `other`.

EXAMPLES:

```
sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
```

```
[0 0 0 1 0]
[0 0 0 0 1]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17
```

`scalar()` is an alias for this method:

```
sage: x.scalar(x)
17
```

Todo

Lift to CombinatorialFreeModule.Element as canonical_inner_product

AmbientSpace.**coroot_lattice**()

EXAMPLES:

```
sage: RootSystem(["A",3,1]).ambient_lattice().coroot_lattice()
Ambient lattice of the Root system of type ['A', 3, 1]
```

Todo

Factor out this code with the classical ambient space.

AmbientSpace.**fundamental_weight**(i)

Return the fundamental weight Λ_i in this ambient space.

It is constructed by taking the corresponding fundamental weight of the classical ambient space (or 0 for Λ_0) and raising it to the appropriate level by adding a suitable multiple of $\delta^\vee$.

EXAMPLES:

```
sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight(2)
e[0] + e[1] + e['deltacheck']
sage: RootSystem(['A',3,1]).ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
               2: e[0] + e[1] + e['deltacheck'], 3: e[0] + e[1] + e[2] + e['deltacheck']
sage: RootSystem(['A',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
sage: RootSystem(['A',3,1]).weight_lattice().fundamental_weights().map(attrcall("level"))
Finite family {0: 1, 1: 1, 2: 1, 3: 1}

sage: RootSystem(['B',3,1]).ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
               2: e[0] + e[1] + 2*e['deltacheck'], 3: 1/2*e[0] + 1/2*e[1] + 1/2*e[2] + e
sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: RootSystem(['B',3,1]).weight_lattice().fundamental_weights().map(attrcall("level"))
Finite family {0: 1, 1: 1, 2: 2, 3: 1}
```

In type BC dual, the coefficient of 'delta^vee' is the level divided by 2 to take into account that the null coroot is $2\delta^\vee$:

```
sage: R = CartanType(['BC',3,2]).dual().root_system()
sage: R.ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'],
```

```
                    2: e[0] + e[1] + e['deltacheck'],
                    3: 1/2*e[0] + 1/2*e[1] + 1/2*e[2] + 1/2*e['deltacheck']}
    sage: R.weight_lattice().fundamental_weights().map(attrcall("level"))
    Finite family {0: 2, 1: 2, 2: 2, 3: 1}
    sage: R.ambient_space().null_coroot()
    2*e['deltacheck']
```

By a slight naming abuse this function also accepts "delta" as input so that it can be used to implement the embedding from the extended weight lattice::

```
    sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight("delta")
    e['delta']
```

AmbientSpace.**is_extended**()

Return whether this is a realization of the extended weight lattice: yes!

See also:

- sage.combinat.root_system.weight_space.WeightSpace
- sage.combinat.root_sytem.weight_lattice_realizations.WeightLatticeRealizations.

EXAMPLES:

```
sage: RootSystem(['A',3,1]).ambient_space().is_extended()
True
```

AmbientSpace.**simple_coroot**(i)

Return the i-th simple coroot $\alpha_i^\vee$ of this affine ambient space.

EXAMPLES:

```
sage: RootSystem(["A",3,1]).ambient_space().simple_coroot(1)
e[0] - e[1]
```

It is built as the coroot associated to the simple root α_i:

```
sage: RootSystem(["B",3,1]).ambient_space().simple_roots()
Finite family {0: -e[0] - e[1] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3: e[2]}
sage: RootSystem(["B",3,1]).ambient_space().simple_coroots()
Finite family {0: -e[0] - e[1] + e['deltacheck'], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}
```

Todo

Factor out this code with the classical ambient space.

AmbientSpace.**simple_root**(i)

Return the i-th simple root of this affine ambient space.

EXAMPLES:

It is built straightforwardly from the corresponding simple root α_i in the classical ambient space:

```
sage: RootSystem(["A",3,1]).ambient_space().simple_root(1)
e[0] - e[1]
```

For the special node (typically $i = 0$), α_0 is built from the other simple roots using the column annihilator of the Cartan matrix and adding δ, where δ is the null root:

```
sage: RootSystem(["A",3]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
sage: RootSystem(["A",3,1]).ambient_space().simple_roots()
Finite family {0: -e[0] + e[3] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3: e[2] - e[3]}
```

Here is a twisted affine example:

```
sage: RootSystem(CartanType(["B",3,1]).dual()).ambient_space().simple_roots()
Finite family {0: -e[0] - e[1] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}
```

In fact δ is really $1/a_0$ times the null root (see the discussion in WeightSpace) but this only makes a difference in type BC:

```
sage: L = RootSystem(CartanType(["BC",3,2])).ambient_space()
sage: L.simple_roots()
Finite family {0: -e[0] + e['delta'], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}
sage: L.null_root()
2*e['delta']
```

Note: An alternative would have been to use the default implementation of the simple roots as linear combinations of the fundamental weights. However, as in type A_n it is preferable to take a slight variant to avoid rational coefficient (the usual GL_n vs SL_n issue).

See also:

- simple_root()
- WeightSpace
- CartanType.col_annihilator()
- null_root()

classmethod AmbientSpace.**smallest_base_ring**(*cartan_type*)

Return the smallest base ring the ambient space can be defined on.

This is the smallest base ring for the associated classical ambient space.

See also:

smallest_base_ring()

EXAMPLES:

```
sage: cartan_type = CartanType(["A",3,1])
sage: cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Integer Ring
sage: cartan_type = CartanType(["B",3,1])
sage: cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Rational Field
```

5.1.229 Root system data for dual Cartan types

class sage.combinat.root_system.type_dual.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

Ambient space for a dual finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type by switching the roles of simple roots, fundamental weights, etc.

Note: Recall that, for any finite Cartan type, and in particular the a simply laced one, the dual Cartan type is constructed as another preexisting Cartan type. Furthermore the ambient space for an affine type is constructed from the ambient space for its classical type. Thus this code is not actually currently used.

It is kept for cross-checking and for reference in case it could become useful, e.g., for dual of general Kac-Moody types.

For the doctests, we need to explicitly create a dual type. Subsequently, since reconstruction of the dual of type F_4 is the relabelled Cartan type, pickling fails on the `TestSuite` run.

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4]^*
sage: TestSuite(L).run(skip=["_test_elements","_test_pickling"])
```

dimension()

Return the dimension of this ambient space.

See also:

`sage.combinat.root_system.ambient_space.AmbientSpace.dimension()`

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weights()

Return the fundamental weights.

They are computed from the simple roots by inverting the Cartan matrix. This is acceptable since this is only about ambient spaces for finite Cartan types. Also, we do not have to worry about the usual GL_n vs SL_n catch because type A is self dual.

An alternative would have been to start from the fundamental coweights in the dual ambient space, but those are not yet implemented.

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: L = ct.root_system().ambient_space()
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3, 1, 1, 1), 4: (2, 0, 0, 0)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing F_4 dual by relabelling:

```
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (3/2, 1/2, 1/2, 1/2), 3: (2, 1, 1, 0), 4: (1, 1, 0, 0)}
```

simple_root(i)

Return the `i`-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the dual Cartan type.

EXAMPLES:

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: ct.root_system().ambient_space().simple_root(1)
(0, 1, -1, 0)

sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}

sage: ct.dual().root_system().ambient_space().simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing F_4 dual by relabelling:

```
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 0, 0, 1), 3: (0, 0, 1, -1), 4: (0, 1, -1,
```

class sage.combinat.root_system.type_dual.**CartanType**(*type*)

Bases: sage.combinat.root_system.cartan_type.CartanType_decorator, sage.combinat.root_system.cartan_type.CartanType_crystallographic

A class for dual Cartan types.

The dual of a (crystallographic) Cartan type is a Cartan type with the same index set, but all arrows reversed in the Dynkin diagram (otherwise said, the Cartan matrix is transposed). It shares a lot of properties in common with its dual. In particular, the Weyl group is isomorphic to that of the dual as a Coxeter group.

EXAMPLES:

For all finite Cartan types, and in particular the simply laced ones, the dual Cartan type is given by another preexisting Cartan type:

```
sage: CartanType(['A',4]).dual()
['A', 4]
sage: CartanType(['B',4]).dual()
['C', 4]
sage: CartanType(['C',4]).dual()
['B', 4]
sage: CartanType(['F',4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

So to exercise this class we consider some non simply laced affine Cartan types and also create explicitely F_4^* as a dual cartan type:

```
sage: from sage.combinat.root_system.type_dual import CartanType as CartanTypeDual
sage: F4d = CartanTypeDual(CartanType(['F',4])); F4d
['F', 4]^*
sage: G21d = CartanType(['G',2,1]).dual(); G21d
['G', 2, 1]^*
```

They share many properties with their original Cartan types:

```
sage: F4d.is_irreducible()
True
sage: F4d.is_crystallographic()
True
```

```
sage: F4d.is_simply_laced()
False
sage: F4d.is_finite()
True
sage: G21d.is_finite()
False
sage: F4d.is_affine()
False
sage: G21d.is_affine()
True
```

TESTS:

```
sage: TestSuite(F4d).run(skip=["_test_pickling"])
sage: TestSuite(G21d).run()
```

Note: F4d is pickled by construction as F4.dual() hence the above failure.

---

ascii_art(*label=<function <lambda>>*, *node=None*)

Return an ascii art representation of this Cartan type

(by hacking the ascii art representation of the dual Cartan type)

EXAMPLES:

```
sage: print CartanType(["B", 3, 1]).dual().ascii_art()
    O 0
    |
    |
O---O=<=O
1   2   3
sage: print CartanType(["C", 4, 1]).dual().ascii_art()
O=<=O---O---O=>=O
0   1   2   3   4
sage: print CartanType(["G", 2, 1]).dual().ascii_art()
  3
O=>=O---O
1   2   0
sage: print CartanType(["F", 4, 1]).dual().ascii_art()
O---O---O=<=O---O
0   1   2   3   4
sage: print CartanType(["BC", 4, 2]).dual().ascii_art()
O=>=O---O---O=>=O
0   1   2   3   4
```

dual()

EXAMPLES:

```
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dual()
['F', 4, 1]
```

dynkin_diagram()

EXAMPLES:

```
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dynkin_diagram()
O---O---O=<=O---O
0   1   2   3   4
```

```
F4~*
```

class sage.combinat.root_system.type_dual.**CartanType_affine**(*type*)

Bases: sage.combinat.root_system.type_dual.CartanType, sage.combinat.root_system.cartan_type.CartanType_affine

INPUT:

- type – a Cartan type

EXAMPLES:

```
sage: ct = CartanType(['F',4,1]).dual()
sage: TestSuite(ct).run()
```

TESTS:

```
sage: ct1 = CartanType(['B',3,1]).dual()
sage: ct2 = CartanType(['B',3,1]).dual()
sage: ct3 = CartanType(['D',4,1]).dual()
sage: ct1 == ct2
True
sage: ct1 == ct3
False
```

Test that the produced Cartan type is in the appropriate abstract classes (see trac ticket #13724):

```
sage: from sage.combinat.root_system import cartan_type
sage: ct = CartanType(['B',3,1]).dual()
sage: TestSuite(ct).run()
sage: isinstance(ct, cartan_type.CartanType_simple)
True
sage: isinstance(ct, cartan_type.CartanType_finite)
False
sage: isinstance(ct, cartan_type.CartanType_affine)
True
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
False
```

By default, the dual of a reducible and finite type is not constructed as such:

```
sage: ct = CartanType([['B',4],['A',2]]).dual(); ct
C4xA2
```

In order to exercise the dual infrastructure we force the construction as a dual:

```
sage: from sage.combinat.root_system import type_dual
sage: ct = type_dual.CartanType(CartanType([['B',4],['A',2]])); ct
B4xA2^*
sage: isinstance(ct, type_dual.CartanType)
True
sage: TestSuite(ct).run(skip=["_test_pickling"])
sage: isinstance(ct, cartan_type.CartanType_finite)
True
sage: isinstance(ct, cartan_type.CartanType_simple)
False
sage: isinstance(ct, cartan_type.CartanType_affine)
False
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
```

```
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
False
```

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: CartanType(['A', 7, 2]).basic_untwisted()
['A', 7]
sage: CartanType(['E', 6, 2]).basic_untwisted()
['E', 6]
sage: CartanType(['D', 4, 3]).basic_untwisted()
['D', 4]
```

classical()

Return the classical Cartan type associated with self (which should be affine).

EXAMPLES:

```
sage: CartanType(['A',3,1]).dual().classical()
['A', 3]
sage: CartanType(['B',3,1]).dual().classical()
['C', 3]
sage: CartanType(['F',4,1]).dual().classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: CartanType(['BC',4,2]).dual().classical()
['B', 4]
```

special_node()

Implement `CartanType_affine.special_node()`

The special node of the dual of an affine type T is the special node of T.

EXAMPLES:

```
sage: CartanType(['A',3,1]).dual().special_node()
0
sage: CartanType(['B',3,1]).dual().special_node()
0
sage: CartanType(['F',4,1]).dual().special_node()
0
sage: CartanType(['BC',4,2]).dual().special_node()
0
```

class sage.combinat.root_system.type_dual.**CartanType_finite**(*type*)

Bases: sage.combinat.root_system.type_dual.CartanType, sage.combinat.root_system.cartan_type.CartanType_finite

INPUT:

- `type` – a Cartan type

EXAMPLES:

```
sage: ct = CartanType(['F',4,1]).dual()
sage: TestSuite(ct).run()
```

TESTS:

```
sage: ct1 = CartanType(['B',3,1]).dual()
sage: ct2 = CartanType(['B',3,1]).dual()
sage: ct3 = CartanType(['D',4,1]).dual()
sage: ct1 == ct2
True
sage: ct1 == ct3
False
```

Test that the produced Cartan type is in the appropriate abstract classes (see trac ticket #13724):

```
sage: from sage.combinat.root_system import cartan_type
sage: ct = CartanType(['B',3,1]).dual()
sage: TestSuite(ct).run()
sage: isinstance(ct, cartan_type.CartanType_simple)
True
sage: isinstance(ct, cartan_type.CartanType_finite)
False
sage: isinstance(ct, cartan_type.CartanType_affine)
True
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
False
```

By default, the dual of a reducible and finite type is not constructed as such:

```
sage: ct = CartanType([['B',4],['A',2]]).dual(); ct
C4xA2
```

In order to exercise the dual infrastructure we force the construction as a dual:

```
sage: from sage.combinat.root_system import type_dual
sage: ct = type_dual.CartanType(CartanType([['B',4],['A',2]])); ct
B4xA2^*
sage: isinstance(ct, type_dual.CartanType)
True
sage: TestSuite(ct).run(skip=["_test_pickling"])
sage: isinstance(ct, cartan_type.CartanType_finite)
True
sage: isinstance(ct, cartan_type.CartanType_simple)
False
sage: isinstance(ct, cartan_type.CartanType_affine)
False
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
False
```

5.1.230 Extended Affine Weyl Groups

AUTHORS:

- Daniel Bump (2012): initial version
- Daniel Orr (2012): initial version

- Anne Schilling (2012): initial version
- Mark Shimozono (2012): initial version
- Nicolas M. Thiery (2012): initial version
- Mark Shimozono (2013): twisted affine root systems, multiple realizations, GL_n

sage.combinat.root_system.extended_affine_weyl_group.**ExtendedAffineWeylGroup**(*cartan_type*, *general_linear=None*, ***print_options*)

The extended affine Weyl group.

INPUT:

- `cartan_type` – An affine or finite Cartan type (a finite Cartan type is an abbreviation for its untwisted affinization)
- `general_linear` – (default: None) If True and `cartan_type` indicates untwisted type A, returns the universal central extension
- `print_options` – Special instructions for printing elements (see below)

Mnemonics

- "P" – subgroup of translations
- "Pv" – subgroup of translations in a dual form
- "W0" – classical Weyl group
- "W" – affine Weyl group
- "F" – fundamental group of length zero elements

There are currently six realizations: "PW0", "W0P, "WF", "FW", "PvW0", and "W0Pv".

"PW0" means the semidirect product of "P" with "W0" acting from the right. "W0P" is similar but with "W0" acting from the left. "WF" is the semidirect product of "W" with "F" acting from the right, etc.

Recognized arguments for `print_options` are:

- `print_tuple` – True or False (default: False) If True, elements are printed (a, b), otherwise as $a * b$
- `affine` – Prefix for simple reflections in the affine Weyl group
- `classical` – Prefix for simple reflections in the classical Weyl group
- `translation` – Prefix for the translation elements
- `fundamental` – Prefix for the elements of the fundamental group

These options are not mutable.

The *extended affine Weyl group* was introduced in the following references.

REFERENCES:

Notation

- R – An irreducible affine root system
- I – Set of nodes of the Dynkin diagram of R

- R_0 – The classical subsystem of R
- I_0 – Set of nodes of the Dynkin diagram of R_0
- E – Extended affine Weyl group of type R
- W – Affine Weyl group of type R
- W_0 – finite (classical) Weyl group (of type R_0)
- M – translation lattice for W
- L – translation lattice for E
- F – Fundamental subgroup of E (the length zero elements)
- P – Finite weight lattice
- Q – Finite root lattice
- $P^\vee$ – Finite coweight lattice
- $Q^\vee$ – Finite coroot lattice

Translation lattices

The styles "PW0" and "W0P" use the following lattices:

- Untwisted affine: $L = P^\vee$, $M = Q^\vee$
- Dual of untwisted affine: $L = P$, $M = Q$
- BC_n ($A_{2n}^{(2)}$): $L = M = P$
- Dual of BC_n ($A_{2n}^{(2)\dagger}$): $L = M = P^\vee$

The styles "PvW0" and "W0Pv" use the following lattices:

- Untwisted affine: The weight lattice of the dual finite Cartan type.
- Dual untwisted affine: The same as for "PW0" and "W0P".

For mixed affine type ($A_{2n}^{(2)}$, aka $\tilde{BC}_n$, and their affine duals) the styles "PvW0" and "W0Pv" are not implemented.

Finite and affine Weyl groups W_0 and W

The finite Weyl group W_0 is generated by the simple reflections s_i for $i \in I_0$ where s_i is the reflection across a suitable hyperplane H_i through the origin in the real span V of the lattice M.

R specifies another (affine) hyperplane H_0. The affine Weyl group W is generated by W_0 and the reflection S_0 across H_0.

Extended affine Weyl group E

The complement in V of the set H of hyperplanes obtained from the H_i by the action of W, has connected components called alcoves. W acts freely and transitively on the set of alcoves. After the choice of a certain alcove (the fundamental alcove), there is an induced bijection from W to the set of alcoves under which the identity in W maps to the fundamental alcove.

Then L is the largest sublattice of V, whose translations stabilize the set of alcoves.

There are isomorphisms

$$W \cong M \rtimes W_0 \cong W_0 \ltimes M$$
$$E \cong L \rtimes W_0 \cong W_0 \ltimes L$$

Fundamental group of affine Dynkin automorphisms

Since L acts on the set of alcoves, the group $F = L/M$ may be viewed as a subgroup of the symmetries of the fundamental alcove or equivalently the symmetries of the affine Dynkin diagram. F acts on the set of alcoves and hence on W. Conjugation by an element of F acts on W by permuting the indices of simple reflections.

There are isomorphisms

$$E \cong F \ltimes W \cong W \rtimes F$$

An affine Dynkin node is *special* if it is conjugate to the zero node under some affine Dynkin automorphism.

There is a bijection $i \mapsto \pi_i$ from the set of special nodes to the group F, where π_i is the unique element of F that sends 0 to i. When $L = P$ (resp. $L = P^\vee$) the element π_i is induced (under the isomorphism $F \cong L/M$) by addition of the coset of the i-th fundamental weight (resp. coweight).

The length function of the Coxeter group W may be extended to E by $\ell(w\pi) = \ell(w)$ where $w \in W$ and $\pi \in F$. This is the number of hyperplanes in H separating the fundamental alcove from its image by $w\pi$ (or equivalently w).

It is known that if G is the compact Lie group of adjoint type with root system R_0 then F is isomorphic to the fundamental group of G, or to the center of its simply-connected covering group. That is why we call F the *fundamental group*.

In the future we may want to build an element of the group from an appropriate linear map f on some of the root lattice realizations for this cartan type: W.from_endomorphism(f).

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(["A",2,1]); E
Extended affine Weyl group of type ['A', 2, 1]
sage: type(E)
<class 'sage.combinat.root_system.extended_affine_weyl_group.ExtendedAffineWeylGroup_Class_with_

sage: PW0=E.PW0(); PW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative

sage: W0P = E.W0P(); W0P
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of t

sage: PvW0 = E.PvW0(); PvW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative

sage: W0Pv = E.W0Pv(); W0Pv
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of t

sage: WF = E.WF(); WF
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of t

sage: FW = E.FW(); FW
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Fundamental gro
```

When the realizations are constructed from each other as above, there are built-in coercions between them.

```
sage: F = E.fundamental_group()
sage: x = WF.from_reduced_word([0,1,2]) * WF(F(2)); x
S0*S1*S2 * pi[2]
sage: FW(x)
pi[2] * S1*S2*S0
sage: W0P(x)
s1*s2*s1 * t[-2*Lambdacheck[1] - Lambdacheck[2]]
sage: PW0(x)
t[Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1
sage: PvW0(x)
t[Lambda[1] + 2*Lambda[2]] * s1*s2*s1
```

The translation lattice and its distinguished basis are obtained from `E`:

```
sage: L = E.lattice(); L
Coweight lattice of the Root system of type ['A', 2]
sage: b = E.lattice_basis(); b
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
```

Translation lattice elements can be coerced into any realization:

```
sage: PW0(b[1]-b[2])
t[Lambdacheck[1] - Lambdacheck[2]]
sage: FW(b[1]-b[2])
pi[2] * S0*S1
```

The dual form of the translation lattice and its basis are similarly obtained:

```
sage: Lv = E.dual_lattice(); Lv
Weight lattice of the Root system of type ['A', 2]
sage: bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: FW(bv[1]-bv[2])
pi[2] * S0*S1
```

The abstract fundamental group is accessed from `E`:

```
sage: F = E.fundamental_group(); F
Fundamental group of type ['A', 2, 1]
```

Its elements are indexed by the set of special nodes of the affine Dynkin diagram:

```
sage: E.cartan_type().special_nodes()
(0, 1, 2)
sage: F.special_nodes()
(0, 1, 2)
sage: [F(i) for i in F.special_nodes()]
[pi[0], pi[1], pi[2]]
```

There is a coercion from the fundamental group into each realization:

```
sage: F(2)
pi[2]
sage: WF(F(2))
pi[2]
sage: W0P(F(2))
s2*s1 * t[-Lambdacheck[1]]
sage: W0Pv(F(2))
s2*s1 * t[-Lambda[1]]
```

Using E one may access the classical and affine Weyl groups and their morphisms into each realization:

```
sage: W0 = E.classical_weyl(); W0
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: v = W0.from_reduced_word([1,2,1]); v
s1*s2*s1
sage: PW0(v)
s1*s2*s1
sage: WF(v)
S1*S2*S1
sage: W = E.affine_weyl(); W
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
sage: w = W.from_reduced_word([2,1,0]); w
S2*S1*S0
sage: WF(w)
S2*S1*S0
sage: PW0(w)
t[Lambdacheck[1] - 2*Lambdacheck[2]] * s1
```

Note that for untwisted affine type the dual form of the classical Weyl group is isomorphic to the usual one, but acts on a different lattice and is therefore different to sage:

```
sage: W0v = E.dual_classical_weyl(); W0v
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: v = W0v.from_reduced_word([1,2])
sage: x = PvW0(v); x
s1*s2
sage: y = PW0(v); y
s1*s2
sage: x == y
False
sage: x.parent() == y.parent()
False
```

An element can be created directly from a reduced word:

```
sage: PW0.from_reduced_word([2,1,0])
t[Lambdacheck[1] - 2*Lambdacheck[2]] * s1
```

Here is a demonstration of the printing options:

```
sage: E = ExtendedAffineWeylGroup(["A",2,1], affine="sx", classical="Sx",translation="x",fundame
sage: PW0 = E.PW0()
sage: y = PW0(E.lattice_basis()[1])
sage: y
x[Lambdacheck[1]]
sage: FW = E.FW()
sage: FW(y)
pix[1] * sx2*sx1
sage: PW0.an_element()
x[2*Lambdacheck[1] + 2*Lambdacheck[2]] * Sx1*Sx2
```

Todo

- Implement a "slow" action of E on any affine root or weight lattice realization.
- Implement the level m actions of E and W on the lattices of finite type.
- Implement the relevant methods from the usual affine weyl group
- Implementation by matrices: style "M".

•Use case: implement the Hecke algebra on top of this

The semidirect product construction in sage currently only admits multiplicative groups. Therefore for the styles involving "P" and "Pv", one must convert the additive group of translations L into a multiplicative group by applying the `sage.groups.group_exp.GroupExp` functor.

The general linear case

The general linear group is not semisimple. Sage can build its extended affine Weyl group:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], general_linear=True); E
Extended affine Weyl group of GL(3)
```

If the Cartan type is `['A', n-1, 1]` and the parameter `general_linear` is not True, the extended affine Weyl group that is built will be for SL_n, not GL_n. But if `general_linear` is True, let W_a and W_e be the affine and extended affine Weyl groups. We make the following nonstandard definition: the extended affine Weyl group $W_e(GL_n)$ is defined by

$$W_e(GL_n) = P(GL_n) \rtimes W$$

where W is the finite Weyl group (the symmetric group S_n) and $P(GL_n)$ is the weight lattice of GL_n, which is usually identified with the lattice $\mathbf{Z}^n$ of n-tuples of integers:

```
sage: PW0 = E.PW0(); PW0
Extended affine Weyl group of GL(3) realized by Semidirect product of Multiplicative form of Amb
sage: PW0.an_element()
t[(2, 2, 3)] * s1*s2
```

There is an isomorphism

$$W_e(GL_n) = \mathbf{Z} \ltimes W_a$$

where the group of integers $\mathbf{Z}$ (with generator π) acts on W_a by

$$\pi\, s_i\, \pi^{-1} = s_{i+1}$$

and the indices of the simple reflections are taken modulo n:

```
sage: FW = E.FW(); FW
Extended affine Weyl group of GL(3) realized by Semidirect product of Fundamental group of GL(3)
sage: FW.an_element()
pi[5] * S0*S1*S2
```

We regard $\mathbf{Z}$ as the fundamental group of affine type GL_n:

```
sage: F = E.fundamental_group(); F
Fundamental group of GL(3)
sage: F.special_nodes()
Integer Ring

sage: x = FW.from_fundamental(F(10)); x
pi[10]
sage: x*x
pi[20]
sage: E.PvW0()(x*x)
t[(7, 7, 6)] * s2*s1
```

class sage.combinat.root_system.extended_affine_weyl_group.**ExtendedAffineWeylGroup_Class**(*carta gen- eral_ **pri*

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The parent-with-realization class of an extended affine Weyl group.

class ExtendedAffineWeylGroupFW(*E*)

Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_class.BindableClass

Extended affine Weyl group, realized as the semidirect product of the affine Weyl group by the fundamental group.

INPUT:

- *E* – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Fundamental
```

from_affine_weyl(*w*)

Return the image of *w* under the map of the affine Weyl group into the right (affine Weyl group) factor in the "FW" style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.FW().from_affine_weyl(E.affine_weyl().from_reduced_word([0,2,1]))
(pi[0], S0*S2*S1)
```

from_fundamental(*f*)

Return the image of the fundamental group element *f* into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.FW().from_fundamental(E.fundamental_group()(2))
(pi[2], 1)
```

simple_reflections()

Return the family of simple reflections of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1],print_tuple=True).FW().simple_reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1), 2: (pi[0], S2)}
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupFWElement**

Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the "FW" realization.

action_on_affine_roots(*beta*)

Act by self on the affine root lattice element beta.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
```

```
sage: v = RootSystem(['A',2,1]).root_lattice().an_element(); v
2*alpha[0] + 2*alpha[1] + 3*alpha[2]
sage: x.action_on_affine_roots(v)
alpha[0] + alpha[1]
```

has_descent(*i*, *side='right'*, *positive=False*)

Return whether `self` has descent at i.

INPUT:

- i – an affine Dynkin index.

OPTIONAL:

- `side` – 'left' or 'right' (default: 'right')
- `positive` – True or False (default: False)

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, False), (1, False), (2, True)]
```

to_affine_weyl_right()

Project `self` to the right (affine Weyl group) factor in the "FW" style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().from_translation(E.lattice_basis()[1]); x
pi[1] * S2*S1
sage: x.to_affine_weyl_right()
S2*S1
```

to_fundamental_group()

Return the projection of `self` to the fundamental group in the "FW" style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().from_translation(E.lattice_basis()[2]); x
pi[2] * S1*S2
sage: x.to_fundamental_group()
pi[2]
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupPW0**(*E*)

Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_class.BindableClass

Extended affine Weyl group, realized as the semidirect product of the translation lattice by the finite Weyl group.

INPUT:

- E – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicat
```

S0()

Return the affine simple reflection.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['B',2]).PW0().S0()
t[Lambdacheck[2]] * s2*s1*s2
```

from_classical_weyl(*w*)
Return the image of w under the homomorphism of the classical Weyl group into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup("A3",print_tuple=True)
sage: E.PW0().from_classical_weyl(E.classical_weyl().from_reduced_word([1,2]))
(t[0], s1*s2)
```

from_translation(*la*)
Map the translation lattice element `la` into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau", print_tuple = True)
sage: la = E.lattice().an_element(); la
2*Lambdacheck[1] + 2*Lambdacheck[2]
sage: E.PW0().from_translation(la)
(tau[2*Lambdacheck[1] + 2*Lambdacheck[2]], 1)
```

simple_reflection(*i*)
Return the i-th simple reflection in `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup("G2")
sage: [(i, E.PW0().simple_reflection(i)) for i in E.cartan_type().index_set()]
[(0, t[Lambdacheck[2]] * s2*s1*s2*s1*s2), (1, s1), (2, s2)]
```

simple_reflections()
Return a family for the simple reflections of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup("A3").PW0().simple_reflections()
Finite family {0: t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1, 1: s1, 2: s2, 3: s
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupPW0Element**
Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the "PW0" realization.

action(*la*)
Return the action of `self` on an element `la` of the translation lattice.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0=E.PW0()
sage: x = PW0.an_element(); x
t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2
sage: la = E.lattice().an_element(); la
2*Lambdacheck[1] + 2*Lambdacheck[2]
sage: x.action(la)
-2*Lambdacheck[1] + 4*Lambdacheck[2]
```

has_descent(*i*, *side='right'*, *positive=False*)
Return whether `self` has i as a descent.

INPUT:

- i – an affine Dynkin node

OPTIONAL:

- `side` – 'left' or 'right' (default: 'right')

- positive – True or False (default: False)

EXAMPLES:

```
sage: w = ExtendedAffineWeylGroup(['A',4,2]).PW0().from_reduced_word([0,1]); w
t[Lambda[1]] * s1*s2
sage: w.has_descent(0, side='left')
True
```

to_classical_weyl()

Return the image of self under the homomorphism that projects to the classical Weyl group factor after rewriting it in either style "PW0" or "W0P".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
t[Lambdacheck[1] + Lambdacheck[2]] * s1*s2*s1
sage: s.to_classical_weyl()
s1*s2*s1
```

to_translation_left()

The image of self under the map that projects to the translation lattice factor after factoring it to the left as in style "PW0".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
t[Lambdacheck[1] + Lambdacheck[2]] * s1*s2*s1
sage: s.to_translation_left()
Lambdacheck[1] + Lambdacheck[2]
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupPvW0**(*E*)

Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_class.BindableClass

Extended affine Weyl group, realized as the semidirect product of the dual form of the translation lattice by the finite Weyl group.

INPUT:

- *E* – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicat
```

from_dual_classical_weyl(*w*)

Return the image of *w* under the homomorphism of the dual form of the classical Weyl group into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1],print_tuple=True)
sage: E.PvW0().from_dual_classical_weyl(E.dual_classical_weyl().from_reduced_word([1,2]))
(t[0], s1*s2)
```

from_dual_translation(*la*)

Map the dual translation lattice element la into self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau", print_tuple = True)
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: E.PvW0().from_dual_translation(la)
(tau[2*Lambda[1] + 2*Lambda[2]], 1)
```

simple_reflections()
Return a family for the simple reflections of self.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1, 1: s1, 2: s2, 3: s3}
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupPvW0Element**
Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the "PvW0" realization.

dual_action(*la*)
Return the action of self on an element la of the dual version of the translation lattice.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.PvW0().an_element(); x
t[2*Lambda[1] + 2*Lambda[2]] * s1*s2
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: x.dual_action(la)
-2*Lambda[1] + 4*Lambda[2]
```

has_descent(*i*, *side='right'*, *positive=False*)
Return whether self has i as a descent.

INPUT:

- i - an affine Dynkin index

OPTIONAL:

- side – 'left' or 'right' (default: 'right')
- positive – True or False (default: False)

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',4,2])
sage: w = E.PvW0().from_reduced_word([0,1]); w
t[Lambda[1]] * s1*s2
sage: [(i, w.has_descent(i, side='left')) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]
```

to_dual_classical_weyl()
Return the image of self under the homomorphism that projects to the dual classical Weyl group factor after rewriting it in either style "PvW0" or "W0Pv".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0); s
t[Lambda[1] + Lambda[2]] * s1*s2*s1
sage: s.to_dual_classical_weyl()
s1*s2*s1
```

to_dual_translation_left()
The image of self under the map that projects to the dual translation lattice factor after factoring it to the left as in style "PvW0".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0); s
t[Lambda[1] + Lambda[2]] * s1*s2*s1
sage: s.to_dual_translation_left()
Lambda[1] + Lambda[2]
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupW0P**(*E*)
Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_class.BindableClass

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group by the translation lattice.

INPUT:

- *E* – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0P()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group
```

S0()
Return the zero-th simple reflection in style "W0P".

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["A",3,1]).W0P().S0()
s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]
```

from_classical_weyl(*w*)
Return the image of the classical Weyl group element *w* in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.W0P().from_classical_weyl(E.classical_weyl().from_reduced_word([2,1]))
(s2*s1, t[0])
```

from_translation(*la*)
Return the image of the lattice element la in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.W0P().from_translation(E.lattice().an_element())
(1, t[2*Lambdacheck[1] + 2*Lambdacheck[2]])
```

simple_reflection(*i*)
Return the *i*-th simple reflection in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); W0P = E.W0P()
sage: [(i, W0P.simple_reflection(i)) for i in E.cartan_type().index_set()]
[(0, s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]), (1, s1), (2, s2), (3, s3)]
```

simple_reflections()
Return the family of simple reflections.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["A",3,1]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]], 1: s1, 2: s2, 3:
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupW0PElement**
Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the W0P realization.

has_descent(*i*, *side='right'*, *positive=False*)
Return whether `self` has i as a descent.

INPUT:
- i - an index.

OPTIONAL:
- `side` - 'left' or 'right' (default: 'right')
- `positive` - True or False (default: False)

EXAMPLES:
```
sage: W0P = ExtendedAffineWeylGroup(['A',4,2]).W0P()
sage: w = W0P.from_reduced_word([0,1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True
```

to_classical_weyl()
Project `self` into the classical Weyl group.

EXAMPLES:
```
sage: x = ExtendedAffineWeylGroup(['A',2,1]).W0P().simple_reflection(0); x;
s1*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[2]]
sage: x.to_classical_weyl()
s1*s2*s1
```

to_translation_right()
Project onto the right (translation) factor in the "W0P" style.

EXAMPLES:
```
sage: x = ExtendedAffineWeylGroup(['A',2,1]).W0P().simple_reflection(0); x
s1*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[2]]
sage: x.to_translation_right()
-Lambdacheck[1] - Lambdacheck[2]
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupW0Pv**(*E*)
Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_class.BindableClass

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group, acting on the dual form of the translation lattice.

INPUT:
- E – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:
```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0Pv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group
```

from_dual_classical_weyl(*w*)
Return the image of w under the homomorphism of the dual form of the classical Weyl group into `self`.

EXAMPLES:
```
sage: E = ExtendedAffineWeylGroup(['A',3,1],print_tuple=True)
sage: E.W0Pv().from_dual_classical_weyl(E.dual_classical_weyl().from_reduced_word([1,2]))
(s1*s2, t[0])
```

from_dual_translation(*la*)
Map the dual translation lattice element `la` into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau", print_tuple = True)
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: E.W0Pv().from_dual_translation(la)
(1, tau[2*Lambda[1] + 2*Lambda[2]])
```

simple_reflections()

Return a family for the simple reflections of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).W0Pv().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]], 1: s1, 2: s2, 3: s3}
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupW0PvElement**

Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

The element class for the "W0Pv" realization.

dual_action(*la*)

Return the action of `self` on an element `la` of the dual version of the translation lattice.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.W0Pv().an_element(); x
s1*s2 * t[2*Lambda[1] + 2*Lambda[2]]
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: x.dual_action(la)
-8*Lambda[1] + 4*Lambda[2]
```

has_descent(*i*, *side='right'*, *positive=False*)

Return whether `self` has i as a descent.

INPUT:

- i - an affine Dynkin index

OPTIONAL:

- `side` - 'left' or 'right' (default: 'right')
- `positive` - True or False (default: False)

EXAMPLES:

```
sage: w = ExtendedAffineWeylGroup(['A',4,2]).W0Pv().from_reduced_word([0,1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True
```

to_dual_classical_weyl()

Return the image of `self` under the homomorphism that projects to the dual classical Weyl group factor after rewriting it in either style "PvW0" or "W0Pv".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).W0Pv().simple_reflection(0); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_classical_weyl()
s1*s2*s1
```

to_dual_translation_right()

The image of `self` under the map that projects to the dual translation lattice factor after factoring it to the right as in style "W0Pv".

EXAMPLES:

```
sage: s = ExtendedAffineWeylGroup(['A',2,1]).W0Pv().simple_reflection(0); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_translation_right()
-Lambda[1] - Lambda[2]
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupWF**(E)
Bases: sage.groups.group_semidirect_product.GroupSemidirectProduct, sage.misc.bindable_class.BindableClass

Extended affine Weyl group, realized as the semidirect product of the affine Weyl group by the fundamental group.

INPUT:

- E – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group
```

from_affine_weyl(w)
Return the image of the affine Weyl group element w in self.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['C',2,1],print_tuple=True)
sage: E.WF().from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,0]))
(S1*S2*S1*S0, pi[0])
```

from_fundamental(f)
Return the image of f under the homomorphism from the fundamental group into the right (fundamental group) factor in "WF" style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['E',6,1],print_tuple=True); WF = E.WF(); F = E.fundam
sage: [(x,WF.from_fundamental(x)) for x in F]
[(pi[0], (1, pi[0])), (pi[1], (1, pi[1])), (pi[6], (1, pi[6]))]
```

simple_reflections()
Return the family of simple reflections.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["A",3,1],affine="r").WF().simple_reflections()
Finite family {0: r0, 1: r1, 2: r2, 3: r3}
```

class ExtendedAffineWeylGroup_Class.**ExtendedAffineWeylGroupWFElement**
Bases: sage.groups.group_semidirect_product.GroupSemidirectProductElement

Element class for the "WF" realization.

bruhat_le(x)
Return whether self is less than or equal to x in the Bruhat order.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s", print_tuple=True); WF=E.WF()
sage: r = E.affine_weyl().from_reduced_word
sage: v = r([1,0])
sage: w = r([1,2,0])
sage: v.bruhat_le(w)
True
sage: vv = WF.from_affine_weyl(v); vv
```

```
(s1*s0, pi[0])
sage: ww = WF.from_affine_weyl(w); ww
(s1*s2*s0, pi[0])
sage: vv.bruhat_le(ww)
True
sage: f = E.fundamental_group()(2); f
pi[2]
sage: ff = WF.from_fundamental(f); ff
(1, pi[2])
sage: vv.bruhat_le(ww*ff)
False
sage: (vv*ff).bruhat_le(ww*ff)
True
```

has_descent(*i*, *side='right'*, *positive=False*)

Return whether `self` has i as a descent.

INPUT:

- i – an affine Dynkin index

OPTIONAL:

- `side` – 'left' or 'right' (default: 'right')
- `positive` – True or False (default: False)

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]
```

to_affine_weyl_left()

Project `self` to the left (affine Weyl group) factor in the "WF" style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_affine_weyl_left()
S0*S2
```

to_fundamental_group()

Project `self` to the right (fundamental group) factor in the "WF" style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_fundamental_group()
pi[1]
```

ExtendedAffineWeylGroup_Class.**FW**()

Realizes `self` in "FW"-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Fundamental
```

ExtendedAffineWeylGroup_Class.**PW0**()

Realizes `self` in "PW0"-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicat
```

ExtendedAffineWeylGroup_Class.**PW0_to_WF_func**(*x*)

Implements coercion from style "PW0" to "WF".

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(["A", 2, 1])
sage: x = E.PW0().an_element(); x
t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2
sage: E.PW0_to_WF_func(x)
S0*S1*S2*S0*S1*S0
```

Warning: This function cannot use coercion, because it is used to define the coercion maps.

ExtendedAffineWeylGroup_Class.**PvW0**()

Realizes `self` in "PvW0"-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicat
```

class ExtendedAffineWeylGroup_Class.**Realizations**(*parent_with_realization*)

Bases: `sage.categories.realizations.Category_realization_of_parent`

The category of the realizations of an extended affine Weyl group

class ElementMethods

action(*la*)

Action of `self` on a lattice element `la`.

INPUT:

- `self` – an element of the extended affine Weyl group
- `la` – an element of the translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic "P" in the documentation for `ExtendedAffineWeylGroup()`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.lattice().an_element(); la
2*Lambdacheck[1] + 2*Lambdacheck[2]
sage: x.action(la)
5*Lambdacheck[1] - 3*Lambdacheck[2]
sage: E = ExtendedAffineWeylGroup(['C',2,1],affine="s")
sage: x = E.PW0().from_translation(E.lattice_basis()[1])
sage: x.action(E.lattice_basis()[2])
Lambdacheck[1] + Lambdacheck[2]
```

Warning: Must be implemented by style "PW0".

action_on_affine_roots(*beta*)

Act by `self` on the affine root lattice element `beta`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: beta = E.cartan_type().root_system().root_lattice().an_element(); beta
2*alpha[0] + 2*alpha[1] + 3*alpha[2]
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: x.action_on_affine_roots(beta)
alpha[0] + alpha[1]
```

Warning: Must be implemented by style "FW".

alcove_walk_signs()

Return a signed alcove walk for `self`.

INPUT:

•An element `self` of the extended affine Weyl group.

OUTPUT:

•A 3-tuple (g, `rw`, `signs`).

ALGORITHM:

The element `self` can be uniquely written `self` = g * w where g has length zero and w is an element of the nonextended affine Weyl group. Let w have reduced word `rw`. Starting with g and applying simple reflections from `rw`, one obtains a sequence of extended affine Weyl group elements (that is, alcoves) and simple roots. The signs give the sequence of sides on which the alcoves lie, relative to the face indicated by the simple roots.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); FW=E.FW()
sage: w = FW.from_reduced_word([0,2,1,3,0])*FW.from_fundamental(1); w
pi[1] * S3*S1*S2*S0*S3
sage: w.alcove_walk_signs()
(pi[1], [3, 1, 2, 0, 3], [-1, 1, -1, -1, 1])
```

apply_simple_projection(*i*, *side='right'*, *length_increasing=True*)

Return the product of `self` by the simple reflection s_i if that product is of greater length than `self` and otherwise return `self`.

INPUT:

•`self` – an element of the extended affine Weyl group

•i – a Dynkin node (index of a simple reflection s_i)

•`side` – 'right' or 'left' (default: 'right') according to which side of `self` the reflection s_i should be multiplied

•`length_increasing` – True or False (default True). If False do the above with the word "greater" replaced by "less".

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_projection(1)
S0*S1*S2*S3*S0 * pi[3]
sage: x.apply_simple_projection(1, length_increasing=False)
S0*S1*S2*S3 * pi[3]
```

apply_simple_reflection(*i*, *side='right'*)

Apply the i-th simple reflection to `self`.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_reflection(1)
S0*S1*S2*S3*S0 * pi[3]
sage: x.apply_simple_reflection(0, side='left')
S1*S2*S3 * pi[3]
```

bruhat_le(x)

Return whether `self` <= x in Bruhat order.

INPUT:

- `self` – an element of the extended affine Weyl group
- x – another element with the same parent as `self`

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True); WF=E.WF()
sage: W = E.affine_weyl()
sage: v = W.from_reduced_word([2,1,0])
sage: w = W.from_reduced_word([2,0,1,0])
sage: v.bruhat_le(w)
True
sage: vx = WF.from_affine_weyl(v); vx
(S2*S1*S0, pi[0])
sage: wx = WF.from_affine_weyl(w); wx
(S2*S0*S1*S0, pi[0])
sage: vx.bruhat_le(wx)
True
sage: F = E.fundamental_group()
sage: f = WF.from_fundamental(F(2))
sage: vx.bruhat_le(wx*f)
False
sage: (vx*f).bruhat_le(wx*f)
True
```

Warning: Must be implemented by "WF".

coset_representative(*index_set*, *side='right'*)

Return the minimum length representative in the coset of `self` with respect to the subgroup generated by the reflections given by `index_set`.

INPUT:

- `self` – an element of the extended affine Weyl group
- `index_set` – a subset of the set of Dynkin nodes
- `side` – 'right' or 'left' (default: 'right') the side on which the subgroup acts

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); WF = E.WF()
sage: b = E.lattice_basis()
sage: I0 = E.cartan_type().classical().index_set()
sage: [WF.from_translation(x).coset_representative(index_set=I0) for x in b]
[pi[1], pi[2], pi[3]]
```

dual_action(*la*)

Action of `self` on a dual lattice element `la`.

INPUT:

- `self` – an element of the extended affine Weyl group
- `la` – an element of the dual translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic "Pv" in the documentation for `ExtendedAffineWeylGroup()`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1],affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.dual_lattice().an_element(); la
2*Lambda[1] + 2*Lambda[2]
sage: x.dual_action(la)
5*Lambda[1] - 3*Lambda[2]
sage: E = ExtendedAffineWeylGroup(['C',2,1],affine="s")
sage: x = E.PvW0().from_dual_translation(E.dual_lattice_basis()[1])
sage: x.dual_action(E.dual_lattice_basis()[2])
Lambda[1] + Lambda[2]
```

Warning: Must be implemented by style "PvW0".

face_data(*i*)

Return a description of one of the bounding hyperplanes of the alcove of an extended affine Weyl group element.

INPUT:

- `self` – An element of the extended affine Weyl group
- i – an affine Dynkin node

OUTPUT:

- A 2-tuple (m, β) defined as follows.

ALGORITHM:

Each element of the extended affine Weyl group corresponds to an alcove, and each alcove has a face for each affine Dynkin node. Given the data of `self` and i, let the extended affine Weyl group element `self` act on the affine simple root α_i, yielding a real affine root, which can be expressed uniquely as

$$"self" \cdot \alpha_i = m\delta + \beta$$

where m is an integer (the height of the i-th bounding hyperplane of the alcove of `self`) and β is a classical root (the normal vector for the hyperplane which points towards the alcove).

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',2,1]).PW0().an_element(); x
t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2
sage: x.face_data(0)
(-1, alpha[1])
```

first_descent(*side='right'*, *positive=False*, *index_set=None*)

Return the first descent of `self`.

INPUT:

- `side` – 'left' or 'right' (default: 'right')
- `positive` – True or False (default: False)
- `index_set` – an optional subset of Dynkin nodes

If `index_set` is not None, then the descent must be in the `index_set`.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.first_descent()
0
sage: x.first_descent(side='left')
0
```

```
sage: x.first_descent(positive=True)
1
sage: x.first_descent(side='left',positive=True)
1
```

has_descent(*i*, *side='right'*, *positive=False*)

Return whether `self` * s_i < `self` where s_i is the i-th simple reflection in the realized group.

INPUT:

- `i` – an affine Dynkin index

OPTIONAL:

- `side` – 'right' or 'left' (default: 'right')
- `positive` – True or False (default: False)

If `side``='left'` then the reflection acts on the left. If ``positive` = True then the inequality is reversed.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); WF=E.WF()
sage: F = E.fundamental_group()
sage: x = WF.an_element(); x
S0*S1*S2*S3 * pi[3]
sage: I = E.cartan_type().index_set()
sage: [(i, x.has_descent(i)) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i,side='left')) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i,positive=True)) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

Warning: This method is abstract because it is used in the recursive coercions between "PW0" and "WF" and other methods use this coercion.

is_affine_grassmannian()

Return whether `self` is affine Grassmannian.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0=E.PW0()
sage: F = E.fundamental_group()
sage: [(x,PW0.from_fundamental(x).is_affine_grassmannian()) for x in F]
[(pi[0], True), (pi[1], True), (pi[2], True)]
sage: b = E.lattice_basis()
sage: [(-x,PW0.from_translation(-x).is_affine_grassmannian()) for x in b]
[(-Lambdacheck[1], True), (-Lambdacheck[2], True)]
```

is_grassmannian(*index_set*, *side='right'*)

Return whether `self` is of minimum length in its coset with respect to the subgroup generated by the reflections of `index_set`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: x = PW0.from_translation(E.lattice_basis()[1]); x
t[Lambdacheck[1]]
sage: I = E.cartan_type().index_set()
sage: [(i, x.is_grassmannian(index_set=[i])) for i in I]
[(0, True), (1, False), (2, True), (3, True)]
sage: [(i, x.is_grassmannian(index_set=[i], side='left')) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

is_translation()
Return whether `self` is a translation element or not.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); FW=E.FW()
sage: F = E.fundamental_group()
sage: FW.from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,0])).is_translatio
True
sage: FW.from_translation(E.lattice_basis()[1]).is_translation()
True
sage: FW.simple_reflection(0).is_translation()
False
```

length()
Return the length of `self` in the Coxeter group sense.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: I0 = E.cartan_type().classical().index_set()
sage: [PW0.from_translation(E.lattice_basis()[i]).length() for i in I0]
[3, 4, 3]
```

to_affine_grassmannian()
Return the unique affine Grassmannian element in the same coset of `self` with respect to the finite Weyl group acting on the right.

EXAMPLES:

```
sage: elts = ExtendedAffineWeylGroup(['A',2,1]).PW0().some_elements()
sage: [(x, x.to_affine_grassmannian()) for x in elts]
[(t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2, t[2*Lambdacheck[1] + 2*Lambdacheck[
```

to_affine_weyl_left()
Return the projection of `self` to the affine Weyl group on the left, after factorizing using the style "WF".

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()
sage: b = E.lattice_basis()
sage: [(x,PW0.from_translation(x).to_affine_weyl_left()) for x in b]
[(Lambdacheck[1], S0*S3*S2), (Lambdacheck[2], S0*S3*S1*S0), (Lambdacheck[3], S0*S1*S2
```

Warning: Must be implemented in style "WF".

to_affine_weyl_right()
Return the projection of `self` to the affine Weyl group on the right, after factorizing using the style "FW".

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: b = E.lattice_basis()
sage: [(x,PW0.from_translation(x).to_affine_weyl_right()) for x in b]
[(Lambdacheck[1], S3*S2*S1), (Lambdacheck[2], S2*S3*S1*S2), (Lambdacheck[3], S1*S2*S3
```

Warning: Must be implemented in style "FW".

to_classical_weyl()
Return the image of `self` under the homomorphism to the classical Weyl group.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflection(0).to_classical_weyl(
s1*s2*s3*s2*s1
```

Warning: Must be implemented in style "PW0".

to_dual_classical_weyl()

Return the image of `self` under the homomorphism to the dual form of the classical Weyl group.

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflection(0).to_dual_classi
s1*s2*s3*s2*s1
sage: x.parent()
Weyl Group of type ['A', 3] (as a matrix group acting on the weight lattice)
```

Warning: Must be implemented in style "PvW0".

to_dual_translation_left()

Return the projection of `self` to the dual translation lattice after factorizing it to the left using the style "PvW0".

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflection(0).to_dual_translat
Lambda[1] + Lambda[3]
```

Warning: Must be implemented in style "PvW0".

to_dual_translation_right()

Return the projection of `self` to the dual translation lattice after factorizing it to the right using the style "W0Pv".

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_dual_translati
-Lambda[1] - Lambda[3]
```

Warning: Must be implemented in style "W0Pv".

to_fundamental_group()

Return the image of `self` under the homomorphism to the fundamental group.

EXAMPLES:

```
sage: PW0 = ExtendedAffineWeylGroup(['A',3,1]).PW0()
sage: b = PW0.realization_of().lattice_basis()
sage: [(x, PW0.from_translation(x).to_fundamental_group()) for x in b]
[(Lambdacheck[1], pi[1]), (Lambdacheck[2], pi[2]), (Lambdacheck[3], pi[3])]
```

Warning: Must be implemented in style "WF".

to_translation_left()

Return the projection of `self` to the translation lattice after factorizing it to the left using the style "PW0".

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_le
Lambdacheck[1] + Lambdacheck[3]
```

Warning: Must be implemented in style "PW0".

to_translation_right()
Return the projection of `self` to the translation lattice after factorizing it to the right using the style "W0P".

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_ri
-Lambdacheck[1] - Lambdacheck[3]
```

Warning: Must be implemented in style "W0P".

class ExtendedAffineWeylGroup_Class.Realizations.**ParentMethods**

from_affine_weyl(w)
Return the image of w under the homomorphism from the affine Weyl group into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: W = E.affine_weyl()
sage: w = W.from_reduced_word([2,1,3,0])
sage: x = PW0.from_affine_weyl(w); x
t[Lambdacheck[1] - 2*Lambdacheck[2] + Lambdacheck[3]] * s3*s1
sage: FW = E.FW()
sage: y = FW.from_affine_weyl(w); y
S2*S3*S1*S0
sage: FW(x) == y
True
```

Warning: Must be implemented in style "WF" and "FW".

from_classical_weyl(w)
Return the image of w from the finite Weyl group into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([2,1,3])
sage: y = PW0.from_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PW0
True
sage: y.to_classical_weyl() == w
True
sage: W0P = E.W0P()
sage: z = W0P.from_classical_weyl(w); z
s2*s3*s1
sage: z.parent() == W0P
True
sage: W0P(y) == z
True
sage: FW = E.FW()
```

```
sage: x = FW.from_classical_weyl(w); x
S2*S3*S1
sage: x.parent() == FW
True
sage: FW(y) == x
True
sage: FW(z) == x
True
```

Warning: Must be implemented in style "PW0" and "W0P".

from_dual_classical_weyl(*w*)

Return the image of w from the finite Weyl group of dual form into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PvW0 = E.PvW0()
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([2,1,3])
sage: y = PvW0.from_dual_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PvW0
True
sage: y.to_dual_classical_weyl() == w
True
sage: x = E.FW().from_dual_classical_weyl(w); x
S2*S3*S1
sage: PvW0(x) == y
True
```

Warning: Must be implemented in style "PvW0" and "W0Pv".

from_dual_translation(*la*)

Return the image of `la` under the homomorphism of the dual version of the translation lattice into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PvW0 = E.PvW0()
sage: bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: x = PvW0.from_dual_translation(2*bv[1]-bv[2]); x
t[2*Lambda[1] - Lambda[2]]
sage: FW = E.FW()
sage: y = FW.from_dual_translation(2*bv[1]-bv[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True
```

from_fundamental(*x*)

Return the image of x under the homomorphism from the fundamental group into `self`.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',3,1])
sage: PW0=E.PW0()
sage: F = E.fundamental_group()
sage: Is = F.special_nodes()
sage: [(i, PW0.from_fundamental(F(i))) for i in Is]
[(0, 1), (1, t[Lambdacheck[1]] * s1*s2*s3), (2, t[Lambdacheck[2]] * s2*s3*s1*s2), (3,
```

```
sage: [(i, E.W0P().from_fundamental((F(i)))) for i in Is]
[(0, 1), (1, s1*s2*s3 * t[-Lambdacheck[3]]), (2, s2*s3*s1*s2 * t[-Lambdacheck[2]]), (
sage: [(i, E.WF().from_fundamental(F(i))) for i in Is]
[(0, 1), (1, pi[1]), (2, pi[2]), (3, pi[3])]
```

Warning: This method must be implemented by the "WF" and "FW" realizations.

from_reduced_word(*word*)

Converts an affine or finite reduced word into a group element.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0().from_reduced_word([1,0,1,2])
t[-Lambdacheck[1] + 2*Lambdacheck[2]]
```

from_translation(*la*)

Return the element of translation by `la` in `self`.

INPUT:

- `self` – a realization of the extended affine Weyl group
- `la` – an element of the translation lattice

In the notation of the documentation for `ExtendedAffineWeylGroup()`, `la` must be an element of "P".

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0=E.PW0()
sage: b = E.lattice_basis(); b
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
sage: x = PW0.from_translation(2*b[1]-b[2]); x
t[2*Lambdacheck[1] - Lambdacheck[2]]
sage: FW = E.FW()
sage: y = FW.from_translation(2*b[1]-b[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True
```

Since the implementation as a semidirect product requires wrapping the lattice group to make it multiplicative, we cannot declare that this map is a morphism for sage `Groups()`.

Warning: This method must be implemented by the "PW0" and "W0P" realizations.

simple_reflection(*i*)

Return the i-th simple reflection in `self`.

INPUT:

- `self` – a realization of the extended affine Weyl group
- i – An affine Dynkin node

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0)
t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1
sage: ExtendedAffineWeylGroup(['C',2,1]).WF().simple_reflection(0)
S0
sage: ExtendedAffineWeylGroup(['D',3,2]).PvW0().simple_reflection(1)
s1
```

simple_reflections()

Return a family from the set of affine Dynkin nodes to the simple reflections in the realization of the extended affine Weyl group.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]], 1: s1, 2: s2,
sage: ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflections()
Finite family {0: S0, 1: S1, 2: S2, 3: S3}
sage: ExtendedAffineWeylGroup(['A',3,1], print_tuple=True).FW().simple_reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1), 2: (pi[0], S2), 3: (pi[0], S3)}
sage: ExtendedAffineWeylGroup(['A',3,1],fundamental="f",print_tuple=True).FW().simple
Finite family {0: (f[0], S0), 1: (f[0], S1), 2: (f[0], S2), 3: (f[0], S3)}
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1, 1: s1, 2: s2, 3: s3}
```

ExtendedAffineWeylGroup_Class.Realizations.**super_categories**()

EXAMPLES:

```
sage: R = ExtendedAffineWeylGroup(['A',2,1]).Realizations(); R
Category of realizations of Extended affine Weyl group of type ['A', 2, 1]
sage: R.super_categories()
[Category of associative inverse realizations of unital magmas]
```

ExtendedAffineWeylGroup_Class.**W0P**()

Realizes `self` in "W0P"-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0P()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group
```

ExtendedAffineWeylGroup_Class.**W0Pv**()

Realizes `self` in "W0Pv"-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).W0Pv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group
```

ExtendedAffineWeylGroup_Class.**WF**()

Realizes `self` in "WF"-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group
```

ExtendedAffineWeylGroup_Class.**WF_to_PW0_func**(*x*)

Coercion from style "WF" to "PW0".

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(["A", 2, 1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: E.WF_to_PW0_func(x)
t[Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1
```

Warning: Since this is used to define some coercion maps it cannot itself use coercion.

ExtendedAffineWeylGroup_Class.**a_realization**()

Return the default realization of an extended affine Weyl group.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).a_realization()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicat
```

ExtendedAffineWeylGroup_Class.**affine_weyl**()

Return the affine Weyl group of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).affine_weyl()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).affine_weyl()
Weyl Group of type ['B', 3, 1]^* (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).affine_weyl()
Weyl Group of type ['BC', 2, 2] (as a matrix group acting on the root lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).affine_weyl()
Weyl Group of type ['BC', 2, 2]^* (as a matrix group acting on the root lattice)
```

ExtendedAffineWeylGroup_Class.**cartan_type**()

The Cartan type of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(["D",3,2]).cartan_type()
['C', 2, 1]^*
```

ExtendedAffineWeylGroup_Class.**classical_weyl**()

Return the classical Weyl group of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the coweight lattice)
```

ExtendedAffineWeylGroup_Class.**classical_weyl_to_affine**(w)

The image of w under the homomorphism from the classical Weyl group into the affine Weyl group.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([1,2]); w
s1*s2
sage: v = E.classical_weyl_to_affine(w); v
S1*S2
```

ExtendedAffineWeylGroup_Class.**dual_classical_weyl**()

Return the dual version of the classical Weyl group of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
```

ExtendedAffineWeylGroup_Class.**dual_classical_weyl_to_affine**(*w*)

The image of w under the homomorphism from the dual version of the classical Weyl group into the affine Weyl group.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([1,2]); w
s1*s2
sage: v = E.dual_classical_weyl_to_affine(w); v
S1*S2
```

ExtendedAffineWeylGroup_Class.**dual_lattice**()

Return the dual version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice()
Weight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice()
Weight lattice of the Root system of type ['C', 3]
```

ExtendedAffineWeylGroup_Class.**dual_lattice_basis**()

Return the distinguished basis of the dual version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
```

ExtendedAffineWeylGroup_Class.**exp_dual_lattice**()

Return the multiplicative version of the dual version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).exp_dual_lattice()
Multiplicative form of Weight lattice of the Root system of type ['A', 2]
```

ExtendedAffineWeylGroup_Class.**exp_lattice**()

Return the multiplicative version of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).exp_lattice()
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
```

ExtendedAffineWeylGroup_Class.**fundamental_group**()

Return the abstract fundamental group.

EXAMPLES:

```
sage: F = ExtendedAffineWeylGroup(['D',5,1]).fundamental_group(); F
Fundamental group of type ['D', 5, 1]
sage: [a for a in F]
[pi[0], pi[1], pi[4], pi[5]]
```

ExtendedAffineWeylGroup_Class.**group_generators**()

Return a set of generators for the default realization of `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).group_generators()
(t[Lambdacheck[1]], t[Lambdacheck[2]], s1, s2)
```

ExtendedAffineWeylGroup_Class.**lattice**()

Return the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).lattice()
Coweight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).lattice()
Weight lattice of the Root system of type ['C', 3]
sage: ExtendedAffineWeylGroup(['A',4,2]).lattice()
Weight lattice of the Root system of type ['C', 2]
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice()
Coweight lattice of the Root system of type ['B', 2]
sage: ExtendedAffineWeylGroup(CartanType(['A',2,1]), general_linear=True).lattice()
Ambient space of the Root system of type ['A', 2]
```

ExtendedAffineWeylGroup_Class.**lattice_basis**()

Return the distinguished basis of the translation lattice for `self`.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).lattice_basis()
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
sage: ExtendedAffineWeylGroup(['A',4,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice_basis()
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
```

5.1.231 Fundamental Group of an Extended Affine Weyl Group

AUTHORS:

- Mark Shimozono (2013) initial version

class sage.combinat.root_system.fundamental_group.**FundamentalGroupElement**(*parent*, *x*)

Bases: `sage.structure.element.MultiplicativeGroupElement`

This should not be called directly

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWe
sage: x = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1], prefix="f").an_element()
sage: TestSuite(x).run()
```

act_on_affine_lattice(*wt*)

Act by `self` on the element `wt` of an affine root/weight lattice realization.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: wt = RootSystem(F.cartan_type()).weight_lattice().an_element(); wt
2*Lambda[0] + 2*Lambda[1] + 3*Lambda[2]
```

```
sage: F(3).act_on_affine_lattice(wt)
2*Lambda[0] + 3*Lambda[1] + 2*Lambda[3]
```

Warning: Doesn't work on ambient spaces.

act_on_affine_weyl(*w*)

Act by `self` on the element w of the affine Weyl group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: W = WeylGroup(F.cartan_type(),prefix="s")
sage: w = W.from_reduced_word([2,3,0])
sage: F(1).act_on_affine_weyl(w).reduced_word()
[3, 0, 1]
```

inverse()

Return the inverse element of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: F(1).inverse()
pi[3]
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1], prefix="f")
sage: F(1).inverse()
f[6]
```

value()

Return the special node which indexes the special automorphism `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1], prefix="f")
sage: F.special_nodes()
(0, 1, 2, 3, 4)
sage: x = F(4); x
f[4]
sage: x.value()
4
```

class sage.combinat.root_system.fundamental_group.**FundamentalGroupGL**(*cartan_type*, *prefix='pi'*)

Bases: sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGr

Fundamental group of GL_n. It is just the integers with extra privileges.

Element

alias of FundamentalGroupGLElement

action(*i*)

The action of the i-th automorphism on the affine Dynkin node set.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.action(4)(2)
0
sage: F.action(-4)(2)
1
```

an_element()
An element of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).an_element()
pi[5]
```

dual_node(i)
The node whose special automorphism is inverse to that of i.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.dual_node(2)
-2
```

family()
The family associated with the set of special nodes.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: fam = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).family
sage: fam
Lazy family (<lambda>(i))_{i in Integer Ring}
sage: fam[-3]
-3
```

group_generators()
Return group generators for `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).group_genera
(pi[1],)
```

one()
Return the identity element of the fundamental group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).one()
pi[0]
```

product(x, y)
Return the product of x and y.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.special_nodes()
Integer Ring
sage: F(2)*F(3)
pi[5]
sage: F(1)*F(3)^(-1)
pi[-2]
```

reduced_word(*i*)

A reduced word for the finite permutation part of the special automorphism indexed by i.

More precisely, return a reduced word for the finite Weyl group element u where i-th automorphism (expressed in the extended affine Weyl group) has the form tu where t is a translation element.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.reduced_word(10)
(1, 2)
```

some_elements()

Return some elements of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).some_element
[pi[-2], pi[2], pi[5]]
```

class sage.combinat.root_system.fundamental_group.**FundamentalGroupGLElement**(*parent*, *x*)

Bases: sage.combinat.root_system.fundamental_group.FundamentalGroupElement

This should not be called directly

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWe
sage: x = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1], prefix="f").an_element()
sage: TestSuite(x).run()
```

act_on_classical_ambient(*wt*)

Act by `self` on the classical ambient weight vector `wt`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: f = F.an_element(); f
pi[5]
sage: la = F.cartan_type().classical().root_system().ambient_space().an_element(); la
(2, 2, 3)
sage: f.act_on_classical_ambient(la)
(2, 3, 2)
```

sage.combinat.root_system.fundamental_group.**FundamentalGroupOfExtendedAffineWeylGroup**(*cartan pre- fix='pi gen- eral_li*

Factory for the fundamental group of an extended affine Weyl group.

INPUT:

- `cartan_type` – a Cartan type that is either affine or finite, with the latter being a shorthand for the untwisted affinization
- `prefix` (default: 'pi') – string that labels the elements of the group
- `general_linear` – (default: None, meaning False) In untwisted type A, if True, use the universal central extension

Fundamental group

Associated to each affine Cartan type $\tilde{X}$ is an extended affine Weyl group E. Its subgroup of length-zero elements is called the fundamental group F. The group F can be identified with a subgroup of the group of automorphisms of the affine Dynkin diagram. As such, every element of F can be viewed as a permutation of the set I of affine Dynkin nodes.

Let $0 \in I$ be the distinguished affine node; it is the one whose removal produces the associated finite Cartan type (call it X). A node $i \in I$ is called *special* if some automorphism of the affine Dynkin diagram, sends 0 to i. The node 0 is always special due to the identity automorphism. There is a bijection of the set of special nodes with the fundamental group. We denote the image of i by π_i. The structure of F is determined as follows.

- $\tilde{X}$ is untwisted – F is isomorphic to $P^\vee/Q^\vee$ where $P^\vee$ and $Q^\vee$ are the coweight and coroot lattices of type X. The group $P^\vee/Q^\vee$ consists of the cosets $\omega_i^\vee + Q^\vee$ for special nodes i, where $\omega_0^\vee = 0$ by convention. In this case the special nodes i are the *cominuscule* nodes, the ones such that $\omega_i^\vee(\alpha_j)$ is 0 or 1 for all $j \in I_0 = I \setminus \{0\}$. For i special, addition by $\omega_i^\vee + Q^\vee$ permutes $P^\vee/Q^\vee$ and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.
- $\tilde{X}$ is dual untwisted – (that is, the dual of $\tilde{X}$ is untwisted) F is isomorphic to P/Q where P and Q are the weight and root lattices of type X. The group P/Q consists of the cosets $\omega_i + Q$ for special nodes i, where $\omega_0 = 0$ by convention. In this case the special nodes i are the *minuscule* nodes, the ones such that $\alpha_j^\vee(\omega_i)$ is 0 or 1 for all $j \in I_0$. For i special, addition by $\omega_i + Q$ permutes P/Q and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.
- $\tilde{X}$ is mixed – (that is, not of the above two types) F is the trivial group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWe
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1]); F
Fundamental group of type ['A', 3, 1]

We also implement a fundamental group for GL_n. It is defined to be the group of integers, which is the covering group of the fundamental group Z/nZ for affine SL_n:

```
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True); F
Fundamental group of GL(3)
sage: x = F.an_element(); x
pi[5]
sage: x*x
pi[10]
sage: x.inverse()
pi[-5]
sage: wt = F.cartan_type().classical().root_system().ambient_space().an_element(); wt
(2, 2, 3)
sage: x.act_on_classical_ambient(wt)
(2, 3, 2)
sage: w = WeylGroup(F.cartan_type(),prefix="s").an_element(); w
s0*s1*s2
sage: x.act_on_affine_weyl(w)
s2*s0*s1
```

class sage.combinat.root_system.fundamental_group.**FundamentalGroupOfExtendedAffineWeylGroup_C**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

The group of length zero elements in the extended affine Weyl group.

Element
alias of FundamentalGroupElement

action(*i*)
Return a function which permutes the affine Dynkin node set by the i-th special automorphism.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1])
sage: [[(i, j, F.action(i)(j)) for j in F.index_set()] for i in F.special_nodes()]
[[(0, 0, 0), (0, 1, 1), (0, 2, 2)], [(1, 0, 1), (1, 1, 2), (1, 2, 0)], [(2, 0, 2), (2, 1, 0)
sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['D',4,1])
sage: [[(i, j, G.action(i)(j)) for j in G.index_set()] for i in G.special_nodes()]
[[(0, 0, 0), (0, 1, 1), (0, 2, 2), (0, 3, 3), (0, 4, 4)], [(1, 0, 1), (1, 1, 0), (1, 2, 2),
```

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1],prefix="f").an_element()
f[4]
```

cartan_type()

The Cartan type of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1]).cartan_type()
['A', 3, 1]
```

dual_node(i)

Return the node that indexes the inverse of the i-th element.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1])
sage: [(i, F.dual_node(i)) for i in F.special_nodes()]
[(0, 0), (1, 4), (2, 3), (3, 2), (4, 1)]
sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1])
sage: [(i, G.dual_node(i)) for i in G.special_nodes()]
[(0, 0), (1, 6), (6, 1)]
sage: H = FundamentalGroupOfExtendedAffineWeylGroup(['D',5,1])
sage: [(i, H.dual_node(i)) for i in H.special_nodes()]
[(0, 0), (1, 1), (4, 5), (5, 4)]
```

group_generators()

Return a tuple of generators of the fundamental group.

Warning: This returns the entire group, a necessary behavior because it is used in `__iter__()`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['E',6,1],prefix="f").group_generators()
Finite family {0: f[0], 1: f[1], 6: f[6]}
```

index_set()

The node set of the affine Cartan type of `self`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1]).index_set()
(0, 1, 2)
```

one()

Return the identity element of the fundamental group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: F.one()
pi[0]
```

product(x, y)

Return the product of x and y.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: F.special_nodes()
(0, 1, 2, 3)
sage: F(2)*F(3)
pi[1]
sage: F(1)*F(3)^(-1)
pi[2]
```

reduced_word(i)

Return a reduced word for the finite Weyl group element associated with the i-th special automorphism.

More precisely, for each special node i, `self.reduced_word(i)` is a reduced word for the element v in the finite Weyl group such that in the extended affine Weyl group, the i-th special automorphism is equal to tv where t is a translation element.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: [(i, F.reduced_word(i)) for i in F.special_nodes()]
[(0, ()), (1, (1, 2, 3)), (2, (2, 1, 3, 2)), (3, (3, 2, 1))]
```

special_nodes()

Return the special nodes of `self`.

See `sage.combinat.root_system.cartan_type.special_nodes()`.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffi
sage: FundamentalGroupOfExtendedAffineWeylGroup(['D',4,1]).special_nodes()
(0, 1, 3, 4)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1]).special_nodes()
(0, 1, 2)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['C',3,1]).special_nodes()
(0, 3)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['D',4,2]).special_nodes()
(0, 3)
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).special_node
Integer Ring
```

5.1.232 Root system data for folded Cartan types

AUTHORS:

- Travis Scrimshaw (2013-01-12) - Initial version

class sage.combinat.root_system.type_folded.**CartanTypeFolded**(*cartan_type*, *folding_of*, *orbit*)

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.sage_object.SageObject

A Cartan type realized from a (Dynkin) diagram folding.

Given a Cartan type X, we say $\hat{X}$ is a folded Cartan type of X if there exists a diagram folding of the Dynkin diagram of $\hat{X}$ onto X.

A folding of a simply-laced Dynkin diagram D with index set I is an automorphism σ of D where all nodes any orbit of σ are not connected. The resulting Dynkin diagram $\hat{D}$ is induced by I/σ where we identify edges in $\hat{D}$ which are not incident and add a k-edge if we identify k incident edges and the arrow is pointing towards the indicent note. We denote the index set of $\hat{D}$ by $\hat{I}$, and by abuse of notation, we denote the folding by σ.

We also have scaling factors γ_i for $i \in \hat{I}$ and defined as the unique numbers such that the map $\Lambda_j \mapsto \gamma_j \sum_{i \in \sigma^{-1}(j)} \Lambda_i$ is the smallest proper embedding of the weight lattice of X to $\hat{X}$.

If the Cartan type is simply laced, the default folding is the one induced from the identity map on D.

If X is affine type, the default embeddings we consider here are:

$$\begin{aligned} C_n^{(1)}, A_{2n}^{(2)}, A_{2n}^{(2)\dagger}, D_{n+1}^{(2)} &\hookrightarrow A_{2n-1}^{(1)}, \\ A_{2n-1}^{(2)}, B_n^{(1)} &\hookrightarrow D_{n+1}^{(1)}, \\ E_6^{(2)}, F_4^{(1)} &\hookrightarrow E_6^{(1)}, \\ D_4^{(3)}, G_2^{(1)} &\hookrightarrow D_4^{(1)}, \end{aligned}$$

and were chosen based on virtual crystals. In particular, the diagram foldings extend to crystal morphisms and gives a realization of Kirillov-Reshetikhin crystals for non-simply-laced types as simply-laced types. See [OS-Shimo03] and [FOS09] for more details. Here we can compute $\gamma_i = \max(c)/c_i$ where $(c_i)_i$ are the translation factors of the root system. In a more type-dependent way, we can define γ_i as follows:

1. There exists a unique arrow (multiple bond) in X.
   (a) Suppose the arrow points towards 0. Then $\gamma_i = 1$ for all $i \in I$.
   (b) Otherwise γ_i is the order of σ for all i in the connected component of 0 after removing the arrow, else $\gamma_i = 1$.
2. There is not a unique arrow. Thus $\hat{X} = A_{2n-1}^{(1)}$ and $\gamma_i = 1$ for all $1 \leq i \leq n-1$. If $i \in \{0, n\}$, then $\gamma_i = 2$ if the arrow incident to i points away and is 1 otherwise.

We note that γ_i only depends upon X.

If the Cartan type is finite, then we consider the classical foldings/embeddings induced by the above affine foldings/embeddings:

$$\begin{aligned} C_n &\hookrightarrow A_{2n-1}, \\ B_n &\hookrightarrow D_{n+1}, \\ F_4 &\hookrightarrow E_6, \\ G_2 &\hookrightarrow D_4. \end{aligned}$$

For more information on Cartan types, see sage.combinat.root_system.cartan_type.

Other foldings may be constructed by passing in an optional folding_of second argument. See below.

INPUT:

- `cartan_type` – the Cartan type X to create the folded type
- `folding_of` – the Cartan type $\hat{X}$ which X is a folding of
- `orbit` – the orbit of the Dynkin diagram automorphism σ given as a list of lists where the a-th list corresponds to the a-th entry in I or a dictionary with keys in I and values as lists

Note: If X is an affine type, we assume the special node is fixed under σ.

EXAMPLES:

```
sage: fct = CartanType(['C',4,1]).as_folding(); fct
['C', 4, 1] as a folding of ['A', 7, 1]
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}
```

A simply laced Cartan type can be considered as a virtual type of itself:

```
sage: fct = CartanType(['A',4,1]).as_folding(); fct
['A', 4, 1] as a folding of ['A', 4, 1]
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1,), 2: (2,), 3: (3,), 4: (4,)}
```

Finite types:

```
sage: fct = CartanType(['C',4]).as_folding(); fct
['C', 4] as a folding of ['A', 7]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 1, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

sage: fct = CartanType(['F',4]).dual().as_folding(); fct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1} as a folding of ['E', 6]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 2, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 6), 2: (3, 5), 3: (4,), 4: (2,)}
```

REFERENCES:

- Wikipedia article Dynkin_diagram#Folding

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.cartan_type()
['C', 4, 1]
```

folding_of()

Return the Cartan type of the virtual space.

EXAMPLES:

```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_of()
['A', 7, 1]
```

folding_orbit()
Return the orbits under the automorphism σ as a dictionary (of tuples).

EXAMPLES:

```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}
```

scaling_factors()
Return the scaling factors of `self`.

EXAMPLES:

```
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).dual().as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['BC', 4, 2]).relabel({0:4, 1:3, 2:2, 3:1, 4:0}).as_folding().scaling_facto
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}
```

5.1.233 Root system data for Cartan types with marked nodes

class sage.combinat.root_system.type_marked.**AmbientSpace**(*root_system*, *base_ring*)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace

Ambient space for a marked finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type.

EXAMPLES:

```
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] with nodes (1, 3) marked
sage: TestSuite(L).run()
```

dimension()
Return the dimension of this ambient space.

See also:

sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

EXAMPLES:

```
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weight(*i*)
Return the `i`-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.fundamental_weight(1)
(1, 1, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0),
               3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
```

simple_root(*i*)

Return the `i`-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space()
sage: L.simple_root(1)
(0, 1, -1, 0)
sage: L.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1),
               3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
sage: L.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1),
               3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

class sage.combinat.root_system.type_marked.**CartanType**(*ct*, *marked_nodes*)

Bases: sage.combinat.root_system.cartan_type.CartanType_decorator

A class for Cartan types with marked nodes.

INPUT:

- `ct` – a Cartan type
- `marked_nodes` – a list of marked nodes

EXAMPLES:

We take the Cartan type B_4:

```
sage: T = CartanType(['B',4])
sage: T.dynkin_diagram()
O---O---O=>=O
1   2   3   4
B4
```

And mark some of its nodes:

```
sage: T = T.marked_nodes([2,3])
sage: T.dynkin_diagram()
O---X---X=>=O
1   2   3   4
B4 with nodes (2, 3) marked
```

Markings are not additive:

```
sage: T.marked_nodes([1,4]).dynkin_diagram()
X---O---O=>=X
```

```
1   2   3   4
B4 with nodes (1, 4) marked
```

And trivial relabelling are honoured nicely:

```
sage: T = T.marked_nodes([])
sage: T.dynkin_diagram()
O---O---O=>=O
1   2   3   4
B4
```

ascii_art(*label=<function <lambda>>*, *node=None*)

Return an ascii art representation of this Cartan type.

EXAMPLES:

```
sage: print CartanType(["G", 2]).marked_nodes([2]).ascii_art()
  3
O=<=X
1   2
sage: print CartanType(["B", 3, 1]).marked_nodes([0, 3]).ascii_art()
    X 0
    |
    |
O---O=>=X
1   2   3
sage: print CartanType(["F", 4, 1]).marked_nodes([0, 2]).ascii_art()
X---O---X=>=O---O
0   1   2   3   4
```

dual()

Implements sage.combinat.root_system.cartan_type.CartanType_abstract.dual(), using that taking the dual and marking nodes are commuting operations.

EXAMPLES:

```
sage: T = CartanType(["BC",3, 2])
sage: T.marked_nodes([1,3]).dual().dynkin_diagram()
O=>=X---O=>=X
0   1   2   3
BC3~* with nodes (1, 3) marked
sage: T.dual().marked_nodes([1,3]).dynkin_diagram()
O=>=X---O=>=X
0   1   2   3
BC3~* with nodes (1, 3) marked
```

dynkin_diagram()

Returns the Dynkin diagram for this Cartan type.

EXAMPLES:

```
sage: CartanType(["G", 2]).marked_nodes([2]).dynkin_diagram()
  3
O=<=X
1   2
G2 with node 2 marked
```

TESTS:

To be compared with the examples in ascii_art():

```
sage: sorted(CartanType(["G", 2]).relabel({1:2,2:1}).dynkin_diagram().edges())
[(1, 2, 3), (2, 1, 1)]
sage: sorted(CartanType(["B", 3, 1]).relabel([1,3,2,0]).dynkin_diagram().edges())
[(0, 2, 1), (1, 2, 1), (2, 0, 2), (2, 1, 1), (2, 3, 1), (3, 2, 1)]
sage: sorted(CartanType(["F", 4, 1]).relabel(lambda n: 4-n).dynkin_diagram().edges())
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 2), (2, 3, 1), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

marked_nodes (*marked_nodes*)

Return `self` with nodes `marked_nodes` marked.

EXAMPLES:

```
sage: ct = CartanType(['A',12])
sage: m = ct.marked_nodes([1,4,6,7,8,12]); m
['A', 12] with nodes (1, 4, 6, 7, 8, 12) marked
sage: m.marked_nodes([2])
['A', 12] with node 2 marked
sage: m.marked_nodes([]) is ct
True
```

relabel (*relabelling*)

Return the relabelling of `self`.

EXAMPLES:

```
sage: T = CartanType(["BC",3, 2])
sage: T.marked_nodes([1,3]).relabel(lambda x: x+2).dynkin_diagram()
O=<=X---O=<=X
2   3   4   5
BC3~ relabelled by {0: 2, 1: 3, 2: 4, 3: 5} with nodes (3, 5) marked
sage: T.relabel(lambda x: x+2).marked_nodes([3,5]).dynkin_diagram()
O=<=X---O=<=X
2   3   4   5
BC3~ relabelled by {0: 2, 1: 3, 2: 4, 3: 5} with nodes (3, 5) marked
```

type()

Return the type of `self` or `None` if unknown.

EXAMPLES:

```
sage: ct = CartanType(['F', 4]).marked_nodes([1,3])
sage: ct.type()
'F'
```

class sage.combinat.root_system.type_marked.**CartanType_affine**(*ct*, *marked_nodes*)

Bases: sage.combinat.root_system.type_marked.CartanType, sage.combinat.root_system.cartan_type.CartanType_affine

TESTS:

```
sage: ct = CartanType(['B',3,1]).marked_nodes([1,3])
sage: ct
['B', 3, 1] with nodes (1, 3) marked

sage: L = ct.root_system().ambient_space(); L
Ambient space of the Root system of type ['B', 3, 1] with nodes (1, 3) marked
sage: L.classical()
Ambient space of the Root system of type ['B', 3] with nodes (1, 3) marked
sage: TestSuite(L).run()
```

basic_untwisted()
Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: CartanType(['A', 7, 2]).marked_nodes([1,3]).basic_untwisted()
['A', 7] with nodes (1, 3) marked
sage: CartanType(['D', 4, 3]).marked_nodes([0,2]).basic_untwisted()
['D', 4] with node 2 marked
```

classical()
Return the classical Cartan type associated with `self`.

EXAMPLES:

```
sage: T = CartanType(['A',4,1]).marked_nodes([0,2,4])
sage: T.dynkin_diagram()
0
X-----------+
|           |
|           |
O---X---O---X
1   2   3   4
A4~ with nodes (0, 2, 4) marked

sage: T0 = T.classical()
sage: T0
['A', 4] with nodes (2, 4) marked
sage: T0.dynkin_diagram()
O---X---O---X
1   2   3   4
A4 with nodes (2, 4) marked
```

is_untwisted_affine()
Implements :meth:'CartanType_affine.is_untwisted_affine'.

A marked Cartan type is untwisted affine if the original is.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).is_untwisted_affine()
True
```

special_node()
Return the special node of the Cartan type.

See also:

`special_node()`

It is the special node of the non-marked Cartan type..

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).special_node()
0
```

class sage.combinat.root_system.type_marked.**CartanType_finite**(*ct*, *marked_nodes*)
Bases: sage.combinat.root_system.type_marked.CartanType, sage.combinat.root_system.cartan_type.CartanType_finite

Return an isomorphic Cartan type obtained by marking the nodes of the Dynkin diagram.

TESTS:

Test that the produced Cartan type is in the appropriate abstract classes:

```
sage: ct = CartanType(['B',4]).marked_nodes([1,2])
sage: TestSuite(ct).run()
sage: from sage.combinat.root_system import cartan_type
sage: isinstance(ct, cartan_type.CartanType_finite)
True
sage: isinstance(ct, cartan_type.CartanType_simple)
True
sage: isinstance(ct, cartan_type.CartanType_affine)
False
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
False

sage: ct = CartanType(['A',3,1]).marked_nodes([1,2])
sage: TestSuite(ct).run()
sage: isinstance(ct, cartan_type.CartanType_simple)
True
sage: isinstance(ct, cartan_type.CartanType_finite)
False
sage: isinstance(ct, cartan_type.CartanType_affine)
True
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
True
```

AmbientSpace
alias of AmbientSpace

affine()
Return the affine Cartan type associated with self.

EXAMPLES:

```
sage: B4 = CartanType(['B',4]).marked_nodes([1,3])
sage: B4.dynkin_diagram()
X---O---X=>=O
1   2   3   4
B4 with nodes (1, 3) marked
sage: B4.affine().dynkin_diagram()
    O 0
    |
    |
X---O---X=>=O
1   2   3   4
B4~ with nodes (1, 3) marked
```

TESTS:

Check that we don't inadvertently change the internal marking of ct:

```
sage: ct = CartanType(['F', 4]).marked_nodes([1,3])
sage: ct.affine()
['F', 4, 1] with nodes (1, 3) marked
sage: ct
```

```
['F', 4] with nodes (1, 3) marked
```

5.1.234 Root system data for reducible Cartan types

class sage.combinat.root_system.type_reducible.**AmbientSpace**(*root_system*, *base_ring*)

Bases: sage.combinat.root_system.ambient_space.AmbientSpace

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space()
Ambient space of the Root system of type A2xB2
```

ambient_spaces()

Returns a list of the irreducible Cartan types of which the given reducible Cartan type is a product.

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().ambient_spaces()
[Ambient space of the Root system of type ['A', 2],
 Ambient space of the Root system of type ['B', 2]]
```

cartan_type()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().cartan_type()
A2xB2
```

component_types()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().component_types()
[['A', 2], ['B', 2]]
```

dimension()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().dimension()
5
```

fundamental_weights()

EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0, 0), 2: (1, 1, 0, 0, 0), 3: (0, 0, 0, 1, 0), 4: (0, 0, 0, 1/2,
```

inject_weights(*i*, *v*)

Produces the corresponding element of the lattice.

INPUT:

- i - an integer in range(self.components)
- v - a vector in the i-th component weight lattice

EXAMPLES:

```
sage: V = RootSystem("A2xB2").ambient_space()
sage: [V.inject_weights(i,V.ambient_spaces()[i].fundamental_weights()[1]) for i in range(2)]
[(1, 0, 0, 0, 0), (0, 0, 0, 1, 0)]
```

```
sage: [V.inject_weights(i,V.ambient_spaces()[i].fundamental_weights()[2]) for i in range(2)]
[(1, 1, 0, 0, 0), (0, 0, 0, 1/2, 1/2)]
```

negative_roots()

EXAMPLES:

```
sage: RootSystem("A1xA2").ambient_space().negative_roots()
[(-1, 1, 0, 0, 0), (0, 0, -1, 1, 0), (0, 0, -1, 0, 1), (0, 0, 0, -1, 1)]
```

positive_roots()

EXAMPLES:

```
sage: RootSystem("A1xA2").ambient_space().positive_roots()
[(1, -1, 0, 0, 0), (0, 0, 1, -1, 0), (0, 0, 1, 0, -1), (0, 0, 0, 1, -1)]
```

simple_coroot(*i*)

EXAMPLES:

```
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_coroot(2)
(0, 0, 1, -1)
sage: A.simple_coroots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2)}
```

simple_root(*i*)

EXAMPLES:

```
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_root(2)
(0, 0, 1, -1)
sage: A.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1)}
```

class sage.combinat.root_system.type_reducible.**CartanType**(*types*)

Bases: sage.structure.sage_object.SageObject, sage.combinat.root_system.cartan_type.Cartar

A class for reducible Cartan types.

Reducible root systems are ones that can be factored as direct products. Strictly speaking type D_2 (corresponding to orthogonal groups of degree 4) is reducible since it is isomorphic to $A_1 \times A_1$. However type D_2 is not built using this class for our purposes.

INPUT:

- types - a list of simple Cartan types

EXAMPLES:

```
sage: [t1,t2]=[CartanType(x) for x in ['A',1],['B',2]]
sage: CartanType([t1,t2])
A1xB2
sage: t = CartanType("A2xB2")
```

A reducible Cartan type is finite (resp. crystallographic, simply laced) if all its components are:

```
sage: t.is_finite()
True
sage: t.is_crystallographic()
True
sage: t.is_simply_laced()
False
```

This is implemented by inserting the appropriate abstract super classes (see `_add_abstract_superclass()`):

```
sage: t.__class__.mro()
[<class 'sage.combinat.root_system.type_reducible.CartanType_with_superclass'>, <class 'sage.com
```

The index set of the reducible Cartan type is obtained by relabelling successively the nodes of the Dynkin diagrams of the components by 1,2,...:

```
sage: t = CartanType(["A",4], ["BC",5,2], ["C",3])
sage: t.index_set()
(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13)

sage: t.dynkin_diagram()
O---O---O---O
1   2   3   4
O=<=O---O---O---O=<=O
5   6   7   8   9   10
O---O=<=O
11   12   13
A4xBC5~xC3
```

AmbientSpace
alias of `AmbientSpace`

ascii_art(*label=<function <lambda>>*, *node=None*)
Return an ascii art representation of this reducible Cartan type.

EXAMPLES:

```
sage: print CartanType("F4xA2").ascii_art(label = lambda x: x+2)
O---O=>=O---O
3   4   5   6
O---O
7   8

sage: print CartanType(["BC",5,2], ["A",4]).ascii_art()
O=<=O---O---O---O=<=O
1   2   3   4   5   6
O---O---O---O
7   8   9   10

sage: print CartanType(["A",4], ["BC",5,2], ["C",3]).ascii_art()
O---O---O---O
1   2   3   4
O=<=O---O---O---O=<=O
5   6   7   8   9   10
O---O=<=O
11   12   13
```

cartan_matrix(*subdivide=True*)
Return the Cartan matrix associated with `self`. By default the Cartan matrix is a subdivided block matrix showing the reducibility but the subdivision can be suppressed with the option `subdivide = False`.

Todo

Currently `subdivide` is currently ignored.

EXAMPLES:

```
sage: ct = CartanType("A2","B2")
sage: ct.cartan_matrix()
[ 2 -1| 0  0]
[-1  2| 0  0]
[-----+-----]
[ 0  0| 2 -1]
[ 0  0|-2  2]
sage: ct.cartan_matrix(subdivide=False)
[ 2 -1  0  0]
[-1  2  0  0]
[ 0  0  2 -1]
[ 0  0 -2  2]
```

component_types()

A list of Cartan types making up the reducible type.

EXAMPLES:

```
sage: CartanType(['A',2],['B',2]).component_types()
[['A', 2], ['B', 2]]
```

dual()

EXAMPLES:

```
sage: CartanType("A2xB2").dual()
A2xC2
```

dynkin_diagram()

Returns a Dynkin diagram for type reducible.

EXAMPLES:

```
sage: dd = CartanType("A2xB2xF4").dynkin_diagram()
sage: dd
O---O
1   2
O=>=O
3   4
O---O=>=O---O
5   6   7   8
A2xB2xF4
sage: dd.edges()
[(1, 2, 1), (2, 1, 1), (3, 4, 2), (4, 3, 1), (5, 6, 1), (6, 5, 1), (6, 7, 2), (7, 6, 1), (7,

sage: CartanType("F4xA2").dynkin_diagram()
O---O=>=O---O
1   2   3   4
O---O
5   6
F4xA2
```

index_set()

Implements `CartanType_abstract.index_set()`.

For the moment, the index set is always of the form $\{1, \ldots, n\}$.

EXAMPLES:

```
sage: CartanType("A2","A1").index_set()
(1, 2, 3)
```

is_affine()
Report that this reducible Cartan type is not affine

EXAMPLES:

```
sage: CartanType(['A',2],['B',2]).is_affine()
False
```

is_finite()
EXAMPLES:

```
sage: ct1 = CartanType(['A',2],['B',2])
sage: ct1.is_finite()
True
sage: ct2 = CartanType(['A',2],['B',2,1])
sage: ct2.is_finite()
False
```

TESTS:

```
sage: isinstance(ct1, sage.combinat.root_system.cartan_type.CartanType_finite)
True
sage: isinstance(ct2, sage.combinat.root_system.cartan_type.CartanType_finite)
False
```

is_irreducible()
Report that this Cartan type is not irreducible.

EXAMPLES:

```
sage: ct = CartanType(['A',2],['B',2])
sage: ct.is_irreducible()
False
```

rank()
Returns the rank of self.

EXAMPLES:

```
sage: CartanType("A2","A1").rank()
3
```

type()
Returns "reducible" since the type is reducible.

EXAMPLES:

```
sage: CartanType(['A',2],['B',2]).type()
'reducible'
```

5.1.235 Root system data for relabelled Cartan types

class sage.combinat.root_system.type_relabel.**AmbientSpace**(*root_system*, *base_ring*)
Bases: sage.combinat.root_system.ambient_space.AmbientSpace

Ambient space for a relabelled finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type, by relabelling the simple roots, fundamental weights, etc.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: TestSuite(L).run()
```

dimension()

Return the dimension of this ambient space.

See also:

sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weight(*i*)

Return the `i`-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(["F",4]).root_system().ambient_space()
sage: K.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
sage: L.fundamental_weight(1)
(1, 0, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (2, 1, 1, 0), 4: (3/2, 1/2, 1/2, 1/2)}
```

simple_root(*i*)

Return the `i`-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(["F",4]).root_system().ambient_space()
sage: K.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/
sage: K.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
sage: L.simple_root(1)
(1/2, -1/2, -1/2, -1/2)

sage: L.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0,

sage: L.simple_coroots()
Finite family {1: (1, -1, -1, -1), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 2)}
```

class sage.combinat.root_system.type_relabel.**CartanType**(*type*, *relabelling*)
Bases: sage.combinat.root_system.cartan_type.CartanType_decorator

A class for relabelled Cartan types.

ascii_art(*label=<function <lambda>>*, *node=None*)
Return an ascii art representation of this Cartan type.

EXAMPLES:

```
sage: print CartanType(["G", 2]).relabel({1:2,2:1}).ascii_art()
  3
O=<=O
2   1
sage: print CartanType(["B", 3, 1]).relabel([1,3,2,0]).ascii_art()
    O 1
    |
    |
O---O=>=O
3   2   0
sage: print CartanType(["F", 4, 1]).relabel(lambda n: 4-n).ascii_art()
O---O---O=>=O---O
4   3   2   1   0
```

dual()
Implements sage.combinat.root_system.cartan_type.CartanType_abstract.dual(), using that taking the dual and relabelling are commuting operations.

EXAMPLES:

```
sage: T = CartanType(["BC",3, 2])
sage: cycle = {1:2, 2:3, 3:0, 0:1}
sage: T.relabel(cycle).dual().dynkin_diagram()
O=>=O---O=>=O
1   2   3   0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
sage: T.dual().relabel(cycle).dynkin_diagram()
O=>=O---O=>=O
1   2   3   0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
```

dynkin_diagram()
Returns the Dynkin diagram for this Cartan type.

EXAMPLES:

```
sage: CartanType(["G", 2]).relabel({1:2,2:1}).dynkin_diagram()
  3
O=<=O
2   1
G2 relabelled by {1: 2, 2: 1}
```

TESTS:

To be compared with the examples in ascii_art():

```
sage: sorted(CartanType(["G", 2]).relabel({1:2,2:1}).dynkin_diagram().edges())
[(1, 2, 3), (2, 1, 1)]
sage: sorted(CartanType(["B", 3, 1]).relabel([1,3,2,0]).dynkin_diagram().edges())
[(0, 2, 1), (1, 2, 1), (2, 0, 2), (2, 1, 1), (2, 3, 1), (3, 2, 1)]
sage: sorted(CartanType(["F", 4, 1]).relabel(lambda n: 4-n).dynkin_diagram().edges())
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 2), (2, 3, 1), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

index_set()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.index_set()
(1, 2)
```

type()

Return the type of `self` or `None` if unknown.

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.type()
'G'
```

class sage.combinat.root_system.type_relabel.**CartanType_affine**(*type*, *relabelling*)

Bases: sage.combinat.root_system.type_relabel.CartanType, sage.combinat.root_system.cartan_type.CartanType_affine

TESTS:

```
sage: ct = CartanType(['D',4,3]); ct
['G', 2, 1]^* relabelled by {0: 0, 1: 2, 2: 1}

sage: L = ct.root_system().ambient_space(); L
Ambient space of the Root system of type ['G', 2, 1]^* relabelled by {0: 0, 1: 2, 2: 1}
sage: L.classical()
Ambient space of the Root system of type ['G', 2]
sage: TestSuite(L).run()
```

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: ct = CartanType(['A', 5, 2]).relabel({0:1, 1:0, 2:2, 3:3})
sage: ct.basic_untwisted()
['A', 5]
```

classical()

Return the classical Cartan type associated with `self`.

EXAMPLES:

```
sage: A41 = CartanType(['A',4,1])
sage: A41.dynkin_diagram()
0
O-----------+
|           |
|           |
O---O---O---O
1   2   3   4
A4~

sage: T = A41.relabel({0:1, 1:2, 2:3, 3:4, 4:0})
sage: T
['A', 4, 1] relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}
sage: T.dynkin_diagram()
```

```
1
O-----------+
|           |
|           |
O---O---O---O
2   3   4   0
A4~ relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}

sage: T0 = T.classical()
sage: T0
['A', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
sage: T0.dynkin_diagram()
O---O---O---O
2   3   4   0
A4 relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
```

is_untwisted_affine()

Implements :meth:'CartanType_affine.is_untwisted_affine'

A relabelled Cartan type is untwisted affine if the original is.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).is_untwisted_affine()
True
```

special_node()

Returns a special node of the Dynkin diagram

See also:

`special_node()`

It is obtained by relabelling of the special node of the non relabelled Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).special_node()
0
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).special_node()
1
```

class sage.combinat.root_system.type_relabel.**CartanType_finite**(*type*, *relabelling*)

Bases: sage.combinat.root_system.type_relabel.CartanType, sage.combinat.root_system.cartan_type.CartanType_finite

INPUT:

- `type` – a Cartan type
- `relabelling` – a function (or a list, or a dictionary)

Returns an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely the node with label `i` is relabelled `f(i)` (or, by `f[i]` if `f` is a list or dictionary).

EXAMPLES:

We take the Cartan type B_4:

```
sage: T = CartanType(['B',4])
sage: T.dynkin_diagram()
O---O---O=>=O
```

```
1   2   3   4
B4
```

And relabel its nodes:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}

sage: T = T.relabel(cycle)
sage: T.dynkin_diagram()
O---O---O=>=O
2   3   4   1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: sorted(T.dynkin_diagram().edges())
[(1, 4, 1), (2, 3, 1), (3, 2, 1), (3, 4, 1), (4, 1, 2), (4, 3, 1)]
```

Multiple relabelling are recomposed into a single one:

```
sage: T = T.relabel(cycle)
sage: T.dynkin_diagram()
O---O---O=>=O
3   4   1   2
B4 relabelled by {1: 3, 2: 4, 3: 1, 4: 2}

sage: T = T.relabel(cycle)
sage: T.dynkin_diagram()
O---O---O=>=O
4   1   2   3
B4 relabelled by {1: 4, 2: 1, 3: 2, 4: 3}
```

And trivial relabelling are honoured nicely:

```
sage: T = T.relabel(cycle)
sage: T.dynkin_diagram()
O---O---O=>=O
1   2   3   4
B4
```

Test that the produced Cartan type is in the appropriate abstract classes (see trac ticket #13724):

```
sage: ct = CartanType(['B',4]).relabel(cycle)
sage: TestSuite(ct).run()
sage: from sage.combinat.root_system import cartan_type
sage: isinstance(ct, cartan_type.CartanType_finite)
True
sage: isinstance(ct, cartan_type.CartanType_simple)
True
sage: isinstance(ct, cartan_type.CartanType_affine)
False
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
False

sage: ct = CartanType(['A',3,1]).relabel({0:3,1:2, 2:1,3:0})
sage: TestSuite(ct).run()
sage: isinstance(ct, cartan_type.CartanType_simple)
True
sage: isinstance(ct, cartan_type.CartanType_finite)
False
sage: isinstance(ct, cartan_type.CartanType_affine)
```

```
True
sage: isinstance(ct, cartan_type.CartanType_crystallographic)
True
sage: isinstance(ct, cartan_type.CartanType_simply_laced)
True
```

Check for the original issues of trac ticket #13724:

```
sage: A3 = CartanType("A3")
sage: A3.cartan_matrix()
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
sage: A3r = A3.relabel({1:2,2:3,3:1})
sage: A3r.cartan_matrix()
[ 2  0 -1]
[ 0  2 -1]
[-1 -1  2]

sage: ct = CartanType(["D",4,3]).classical(); ct
['G', 2]
sage: ct.symmetrizer()
Finite family {1: 1, 2: 3}
```

AmbientSpace
alias of AmbientSpace

affine()
Return the affine Cartan type associated with self.

EXAMPLES:

```
sage: B4 = CartanType(['B',4])
sage: B4.dynkin_diagram()
O---O---O=>=O
1   2   3   4
B4
sage: B4.affine().dynkin_diagram()
    O 0
    |
    |
O---O---O=>=O
1   2   3   4
B4~
```

If possible, this reuses the original label for the special node:

```
sage: T = B4.relabel({1:2, 2:3, 3:4, 4:1}); T.dynkin_diagram()
O---O---O=>=O
2   3   4   1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: T.affine().dynkin_diagram()
    O 0
    |
    |
O---O---O=>=O
2   3   4   1
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}
```

Otherwise, it chooses a label for the special_node in $0, 1, ...$:

```
sage: T = B4.relabel({1:0, 2:1, 3:2, 4:3}); T.dynkin_diagram()
O---O---O=>=O
0   1   2   3
B4 relabelled by {1: 0, 2: 1, 3: 2, 4: 3}
sage: T.affine().dynkin_diagram()
    O 4
    |
    |
O---O---O=>=O
0   1   2   3
B4~ relabelled by {0: 4, 1: 0, 2: 1, 3: 2, 4: 3}
```

This failed before trac ticket #13724:

```
sage: ct = CartanType(["G",2]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}

sage: ct = CartanType(["F",4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}
```

Check that we don't inadvertently change the internal relabelling of `ct`:

```
sage: ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

5.1.236 Weight lattice realizations

class sage.combinat.root_system.weight_lattice_realizations.**WeightLatticeRealizations**(*base*, *name=No*

Bases: sage.categories.category_types.Category_over_base_ring

The category of weight lattice realizations over a given base ring

A *weight lattice realization* L over a base ring R is a free module (or vector space if R is a field) endowed with an embedding of the root lattice of some root system. By restriction, this embedding defines an embedding of the root lattice of this root system, which makes L a root lattice realization.

Typical weight lattice realizations over $\mathbf{Z}$ include the weight lattice, and ambient lattice. Typical weight lattice realizations over $\mathbf{Q}$ include the weight space, and ambient space.

To describe the embedding, a weight lattice realization must implement a method `fundamental_weight`(i) returning for each `i() in the index set the image of the fundamental weight Λ_i under the embedding.

In order to be a proper root lattice realization, a weight lattice realization should also implement the scalar product with the coroot lattice; on the other hand, the embedding of the simple roots is given for free.

See also:

- RootSystem
- RootLatticeRealizations
- WeightSpace
- AmbientSpace

EXAMPLES:

Here, we consider the root system of type A_7, and embed the weight lattice element $x = \Lambda_1 + 2\Lambda_3$ in several root lattice realizations:

```
sage: R = RootSystem(["A",7])
sage: Lambda = R.weight_lattice().fundamental_weights()
sage: x = Lambda[2] + 2 * Lambda[5]

sage: L = R.weight_space()
sage: L(x)
Lambda[2] + 2*Lambda[5]

sage: L = R.ambient_lattice()
sage: L(x)
(3, 3, 2, 2, 2, 0, 0, 0)
```

We embed the weight space element $x = \Lambda_1 + 1/2\Lambda_3$ in the ambient space:

```
sage: Lambda = R.weight_space().fundamental_weights()
sage: x = Lambda[2] + 1/2 * Lambda[5]

sage: L = R.ambient_space()
sage: L(x)
(3/2, 3/2, 1/2, 1/2, 1/2, 0, 0, 0)
```

Of course, one can't embed the weight space in the ambient lattice:

```
sage: L = R.ambient_lattice()
sage: L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[2] + 1/2*Lambda[5]) an element of self (=Ambient
```

If K_1 is a subring of K_2, then one could in theory have an embedding from the weight space over K_1 to any weight lattice realization over K_2; this is not implemented:

```
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.ambient_space(K2)

sage: Lambda = R.weight_space(K2).fundamental_weights()
sage: L(Lambda[1])
(1, 0, 0, 0, 0, 0, 0, 0)

sage: Lambda = R.weight_space(K1).fundamental_weights()
sage: L(Lambda[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[1]) an element of self (=Ambient space of the Roo
```

class ElementMethods

symmetric_form(*la*)

Return the symmetric form of `self` with `la`.

Return the pairing $(|)$ on the weight lattice. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

Warning: For affine root systems, if you are not working in the extended weight lattice/space, this may return incorrect results.

EXAMPLES:

```
sage: P = RootSystem(['C',2]).weight_lattice()
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[2].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....:     for i in P.index_set() for j in P.index_set())
True

sage: P = RootSystem(['C',2,1]).weight_lattice(extended=True)
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[1].symmetric_form(al[0])
-2
sage: al[0].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2,1]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....:     for i in P.index_set() for j in P.index_set())
True
sage: La = P.basis()
sage: [La['delta'].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[1, 0, 0]

sage: P = RootSystem(['C',2,1]).weight_lattice()
sage: Q = RootSystem(['C',2,1]).root_lattice()
sage: al = P.simple_roots()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....:     for i in P.index_set() for j in P.index_set())
True
```

The result of $(\Lambda_0|\alpha_0)$ should be 1, however we get 0 because we are not working in the extended weight lattice:

```
sage: La = P.basis()
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
```

TESTS:

We check that $A_{2n}^{(2)}$ has 3 different root lengths:

```
sage: P = RootSystem(['A',4,2]).weight_lattice()
sage: al = P.simple_roots()
sage: [al[i].symmetric_form(al[i]) for i in P.index_set()]
[2, 4, 8]
```

to_weight_space(*base_ring=None*)

Map `self` to the weight space.

Warning: Implemented for finite Cartan type.

EXAMPLES:

```
sage: b = CartanType(['B',2]).root_system().ambient_space().from_vector(vector([1,-2]));
(1, -2)
sage: b.to_weight_space()
3*Lambda[1] - 4*Lambda[2]
sage: b = CartanType(['B',2]).root_system().ambient_space().from_vector(vector([1/2,0]))
(1/2, 0)
sage: b.to_weight_space()
1/2*Lambda[1]
sage: b.to_weight_space(ZZ)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
sage: b = CartanType(['G',2]).root_system().ambient_space().from_vector(vector([4,-5,1]))
(4, -5, 1)
sage: b.to_weight_space()
-6*Lambda[1] + 5*Lambda[2]
```

class WeightLatticeRealizations.**ParentMethods**

dynkin_diagram_automorphism_of_alcove_morphism(*f*)

Returns the Dynkin diagram automorphism induced by an alcove morphism

INPUT:

- `f` - a linear map from `self` to `self` which preserves alcoves

This method returns the Dynkin diagram automorphism for the decomposition $f = dw$ (see `reduced_word_of_alcove_morphism()`), as a dictionary mapping elements of the index set to itself.

EXAMPLES:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
```

Translations by elements of the root lattice induce a trivial Dynkin diagram automorphism:

```
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[0].translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[2].translation)
{0: 0, 1: 1, 2: 2}
```

This is no more the case for translations by general elements of the (classical) weight lattice at level 0:

```
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - Lambda[0]
```

```
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 2, 2: 0}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 2, 1: 0, 2: 1}

sage: R = RootSystem(['C',2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].translation)
{0: 2, 1: 1, 2: 0}

sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 0, 2: 2, 3: 3, 4: 5, 5: 4}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 0, 1: 1, 2: 2, 3: 3, 4: 4, 5: 5}
```

Algorithm: computes w of the decomposition, and see how $f \circ w^{-1}$ permutes the simple roots.

embed_at_level (*x*, *level=1*)

Embed the classical weight x in the level `level` hyperplane

This is achieved by translating the straightforward embedding of x by $c\Lambda_0$ for c some appropriate scalar.

INPUT:

- `x` – an element of the corresponding classical weight/ambient lattice
- `level` – an integer or element of the base ring (default: 1)

EXAMPLES:

```
sage: L = RootSystem(["B",3,1]).weight_space()
sage: L0 = L.classical()
sage: alpha = L0.simple_roots()
sage: omega = L0.fundamental_weights()
sage: L.embed_at_level(omega[1], 1)
Lambda[1]
sage: L.embed_at_level(omega[2], 1)
-Lambda[0] + Lambda[2]
sage: L.embed_at_level(omega[3], 1)
Lambda[3]
sage: L.embed_at_level(alpha[1], 1)
Lambda[0] + 2*Lambda[1] - Lambda[2]
```

fundamental_weight (*i*)

Returns the i^{th} fundamental weight

INPUT:

- `i` – an element of the index set

By a slight notational abuse, for an affine type this method should also accept `"delta"` as input, and return the image of δ of the extended weight lattice in this realization.

This should be overridden by any subclass, and typically be implemented as a cached method for efficiency.

EXAMPLES:

```
sage: L = RootSystem(["A",3]).ambient_lattice()
sage: L.fundamental_weight(1)
(1, 0, 0, 0)
```

```
sage: L = RootSystem(["A",3,1]).weight_lattice(extended=True)
sage: L.fundamental_weight(1)
Lambda[1]
sage: L.fundamental_weight("delta")
delta
```

TESTS:

```
sage: super(sage.combinat.root_system.weight_space.WeightSpace, L).fundamental_weight(1)
Traceback (most recent call last):
...
NotImplementedError: <abstract method fundamental_weight at ...>
```

fundamental_weights()

Returns the family $(\Lambda_i)_{i \in I}$ of the fundamental weights.

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: f = e.fundamental_weights()
sage: [f[i] for i in [1,2,3]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

is_extended()

Returns whether this is a realization of the extended weight lattice

See also:

sage.combinat.root_system.weight_space.WeightSpace

EXAMPLES:

```
sage: RootSystem(["A",3,1]).weight_lattice().is_extended()
False
sage: RootSystem(["A",3,1]).weight_lattice(extended=True).is_extended()
True
```

This method is irrelevant for finite root systems, since the weight lattice need not be extended to ensure that the root lattice embeds faithfully:

```
sage: RootSystem(["A",3]).weight_lattice().is_extended()
False
```

reduced_word_of_alcove_morphism(f)

INPUT:

- f – a linear map from `self` to `self` which preserves alcoves.

Let A be the fundamental alcove. This returns a reduced word $i_1, ..., i_k$ such that the affine Weyl group element $w = s_{i_1} \circ \cdots \circ s_{i_k}$ maps the alcove $f(A)$ back to A. In other words, the alcove walk $i_1, ..., i_k$ brings the fundamental alcove to the corresponding translated alcove.

Let us throw in a bit of context to explain the main use case. It is customary to realize the alcove picture in the coroot or coweight lattice $R^\vee$. The extended affine Weyl group is then the group of linear maps on $R^\vee$ which preserve the alcoves. By [Kac "Infinite-dimensional Lie algebra", Proposition 6.5] the affine Weyl group is the semidirect product of the associated finite Weyl group and the group of translations in the coroot lattice (the extended affine Weyl group uses the coweight lattice instead). In other words, an element of the extended affine Weyl group admits a unique decomposition of the form:

$$f = dw,$$

where w is in the Weyl group, and d is a function which maps the fundamental alcove to itself. As d permutes the walls of the fundamental alcove, it permutes accordingly the corresponding simple roots, which induces an automorphism of the Dynkin diagram.

This method returns a reduced word for w, whereas the method dynkin_diagram_automorphism_of_alcove_morphism() returns d as a permutation of the nodes of the Dynkin diagram.

Nota bene: recall that the coroot (resp. coweight) lattice is implemented as the root (resp weight) lattice of the dual root system. Hence, this method is implemented for weight lattice realizations, but in practice is most of the time used on the dual side.

EXAMPLES:

We start with type A which is simply laced; hence we do not have to worry about the distinction between the weight and coweight lattice:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
```

We consider first translations by elements of the root lattice:

```
sage: R.reduced_word_of_alcove_morphism(alpha[0].translation)
[1, 2, 1, 0]
sage: R.reduced_word_of_alcove_morphism(alpha[1].translation)
[0, 2, 0, 1]
sage: R.reduced_word_of_alcove_morphism(alpha[2].translation)
[0, 1, 0, 2]
```

We continue with translations by elements of the classical weight lattice, embedded at level 0:
sage: omega1 = Lambda[1] - Lambda[0] sage: omega2 = Lambda[2] - Lambda[0]

sage: R.reduced_word_of_alcove_morphism(omega1.translation) [0, 2] sage: R.reduced_word_of_alcove_morphism(omega2.translation) [0, 1]

The following tests ensure that the code agrees with the tables in Kashiwara's private notes on affine quantum algebras (2008).

TESTS:

```
sage: R = RootSystem(['A',5,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: R.reduced_word_of_alcove_morphism(omega1.translation)
[0, 5, 4, 3, 2]
sage: R.reduced_word_of_alcove_morphism(alpha[0].translation)
[1, 2, 3, 4, 5, 4, 3, 2, 1, 0]

sage: R = RootSystem(['C',3,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: Lambda = R.fundamental_weights()
sage: omega1 = 2*(Lambda[1] - Lambda[0])
sage: omega2 = 2*(Lambda[2] - Lambda[0])
sage: omega3 = Lambda[3] - Lambda[0]
sage: R.reduced_word_of_alcove_morphism(omega1.translation)
[0, 1, 2, 3, 2, 1]
sage: R.reduced_word_of_alcove_morphism(omega2.translation)
[0, 1, 0, 2, 1, 3, 2, 1, 3, 2]
sage: R.reduced_word_of_alcove_morphism(omega3.translation)
[0, 1, 0, 2, 1, 0]
sage: W = WeylGroup(['C',3,1])
sage: s = W.simple_reflections()
sage: w = s[0]*s[1]*s[2]*s[3]*s[2]
sage: W.from_reduced_word(R.reduced_word_of_alcove_morphism(omega2.translation)) == w*w
True
```

```
sage: w = s[0]*s[1]*s[2]*s[0]*s[1]*s[0]
sage: W.from_reduced_word(R.reduced_word_of_alcove_morphism(omega3.translation)) == w
True

sage: R = RootSystem(['D',4,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: omega3 = Lambda[3] - Lambda[0]
sage: omega4 = Lambda[4] - Lambda[0]
sage: R.reduced_word_of_alcove_morphism(omega1.translation)
[0, 2, 3, 4, 2, 0]
sage: R.reduced_word_of_alcove_morphism(omega2.translation)
[0, 2, 1, 3, 2, 4, 2, 1, 3, 2]
sage: R.reduced_word_of_alcove_morphism(omega3.translation)
[0, 2, 1, 4, 2, 0]
sage: R.reduced_word_of_alcove_morphism(omega4.translation)
[0, 2, 1, 3, 2, 0]
sage: W = WeylGroup(['D',4,1])
sage: s = W.simple_reflections()
sage: w = s[0]*s[2]*s[3]*s[4]*s[2]
sage: w1= s[1]*s[2]*s[3]*s[4]*s[2]
sage: W.from_reduced_word(R.reduced_word_of_alcove_morphism(omega2.translation)) == w*w1
True

sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.reduced_word_of_alcove_morphism(omega1.translation)
[0, 2, 3, 4, 5, 3, 2, 0]
sage: W = WeylGroup(['D',5,1])
sage: s = W.simple_reflections()
sage: w = s[0]*s[2]*s[3]*s[4]*s[5]*s[3]*s[2]
sage: w1= s[1]*s[2]*s[3]*s[4]*s[5]*s[3]*s[2]
sage: W.from_reduced_word(R.reduced_word_of_alcove_morphism(omega2.translation)) == w*w1
True
```

reduced_word_of_translation(*t*)

Given an element of the root lattice, this returns a reduced word $i_1, ..., i_k$ such that the Weyl group element $s_{i_1} \circ \cdots \circ s_{i_k}$ implements the "translation" where x maps to $x + level(x) * t$. In other words, the alcove walk $i_1, ..., i_k$ brings the fundamental alcove to the corresponding translated alcove.

Note: there are some technical conditions for t to actually be a translation; those are not tested (TODO: detail).

EXAMPLES:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.reduced_word_of_translation(alpha[1])
[0, 2, 0, 1]
sage: R.reduced_word_of_translation(alpha[2])
[0, 1, 0, 2]
sage: R.reduced_word_of_translation(alpha[0])
[1, 2, 1, 0]

sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
```

```
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.reduced_word_of_translation(omega1)
[0, 2, 3, 4, 5, 3, 2, 0]
sage: R.reduced_word_of_translation(omega2)
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

A non simply laced case:

```
sage: R = RootSystem(["C",2,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: c = R.cartan_type().translation_factors()
sage: c
Finite family {0: 1, 1: 2, 2: 1}
sage: R.reduced_word_of_translation((Lambda[1]-Lambda[0]) * c[1])
[0, 1, 2, 1]
sage: R.reduced_word_of_translation((Lambda[2]-Lambda[0]) * c[2])
[0, 1, 0]
```

See also `_test_reduced_word_of_translation()`.

TODO:

- Add a picture in the doc
- Add a method which, given an element of the classical weight lattice, constructs the appropriate value for t

rho()

EXAMPLES:

```
sage: RootSystem(['A',3]).ambient_lattice().rho()
(3, 2, 1, 0)
```

rho_classical()

Return the embedding at level 0 of ρ of the classical lattice.

EXAMPLES:

```
sage: RootSystem(['C',4,1]).weight_lattice().rho_classical()
-4*Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3] + Lambda[4]
sage: L = RootSystem(['D',4,1]).weight_lattice()
sage: L.rho_classical().scalar(L.null_coroot())
0
```

Warning: In affine type BC dual, this does not live in the weight lattice:

```
sage: L = CartanType(["BC",2,2]).dual().root_system().weight_space()
sage: L.rho_classical()
-3/2*Lambda[0] + Lambda[1] + Lambda[2]
sage: L = CartanType(["BC",2,2]).dual().root_system().weight_lattice()
sage: L.rho_classical()
Traceback (most recent call last):
...
ValueError: 5 is not divisible by 2
```

signs_of_alcovewalk(*walk*)

Let walk = $[i_1, \ldots, i_n]$ denote an alcove walk starting from the fundamental alcove y_0, crossing at step 1 the wall i_1, and so on.

For each k, set $w_k = s_{i_1} \circ s_{i_k}$, and denote by $y_k = w_k(y_0)$ the alcove reached after k steps. Then, y_k

is obtained recursively from y_{k-1} by applying the following reflection:

$$y_k = s_{w_{k-1}\alpha_{i_k}} y_{k-1}$$

The step is said positive if $w_{k-1}\alpha_{i_k}$ is a negative root (considering w_{k-1} as element of the classical Weyl group and α_{i_k} as a classical root) and negative otherwise. The algorithm implemented here use the equivalent property:

```
.. MATH:: \langle w_{k-1}^{-1} \rho_0, \alpha^\vee_{i_k}\rangle > 0
```

Where ρ_0 is the sum of the classical fundamental weights embedded at level 0 in this space (see `rho_classical()`), and $\alpha^\vee_{i_k}$ is the simple coroot associated to α_{i_k}.

This function returns a list of the form $[+1, +1, -1, ...]$, where the k^{th} entry denotes whether the k^{th} step was positive or negative.

See equation 3.4, of Ram: Alcove walks ..., arxiv:math/0601343v1 [math.RT]

EXAMPLES:

```
sage: L = RootSystem(['C',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([1,2,0,1,2,1,2,0,1,2])
[-1, -1, 1, -1, 1, 1, 1, 1, 1, 1]

sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,1,2,0,1,2,0,1,2,0])
[1, 1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1]

sage: L = RootSystem(['B',2,1]).coweight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,0,1,2])
[1, -1, 1, -1, 1, 1]
```

Warning: This method currently does not work in the weight lattice for type BC dual because ρ_0 does not live in this lattice (but an integral multiple of it would do the job as well).

simple_root(i)

Returns the i-th simple root

This default implementation takes the i-th simple root in the weight lattice and embeds it in `self`.

EXAMPLES:

Since all the weight lattice realizations in Sage currently implement a simple_root method, we have to call this one by hand:

```
sage: from sage.combinat.root_system.weight_lattice_realizations import WeightLatticeRea
sage: simple_root = WeightLatticeRealizations(QQ).parent_class.simple_root.f
sage: L = RootSystem("A3").ambient_space()
sage: simple_root(L, 1)
(1, -1, 0, 0)
sage: simple_root(L, 2)
(0, 1, -1, 0)
sage: simple_root(L, 3)
(1, 1, 2, 0)
```

Note that this last root differs from the one implemented in `L` by a multiple of the vector `(1,1,1,1)`:

```
sage: L.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

This is a harmless artefact of the SL versus GL interpretation of type A; see the thematic tutorial on Lie Methods and Related Combinatorics in Sage for details.

weyl_dimension(*highest_weight*)
Return the dimension of the highest weight representation of highest weight `highest_weight`.

EXAMPLES:

```
sage: RootSystem(['A',3]).ambient_lattice().weyl_dimension([2,1,0,0])
20
sage: P = RootSystem(['C',2]).weight_lattice()
sage: La = P.basis()
sage: P.weyl_dimension(La[1]+La[2])
16

sage: type(RootSystem(['A',3]).ambient_lattice().weyl_dimension([2,1,0,0]))
<type 'sage.rings.integer.Integer'>
```

`WeightLatticeRealizations.`**super_categories**()
EXAMPLES:

```
sage: from sage.combinat.root_system.weight_lattice_realizations import WeightLatticeRealiza
sage: WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```

5.1.237 Weight lattices and weight spaces

class `sage.combinat.root_system.weight_space.`**WeightSpace**(*root_system*, *base_ring*, *extended*)
Bases: `sage.combinat.free_module.CombinatorialFreeModule`

INPUT:

- `root_system` – a root system
- `base_ring` – a ring R
- `extended` – a boolean (default: False)

The weight space (or lattice if `base_ring` is $\mathbf{Z}$) of a root system is the formal free module $\bigoplus_i R\Lambda_i$ generated by the fundamental weights $(\Lambda_i)_{i\in I}$ of the root system.

This class is also used for coweight spaces (or lattices).

See also:

- `RootSystem()`
- `RootSystem.weight_lattice()` and `RootSystem.weight_space()`
- `WeightLatticeRealizations()`

EXAMPLES:

```
sage: Q = RootSystem(['A', 3]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3]
sage: Q.simple_roots()
Finite family {1: 2*Lambda[1] - Lambda[2], 2: -Lambda[1] + 2*Lambda[2] - Lambda[3], 3: -Lambda[2

sage: Q = RootSystem(['A', 3, 1]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3, 1]
sage: Q.simple_roots()
Finite family {0: 2*Lambda[0] -   Lambda[1]               -   Lambda[3],
               1:  -Lambda[0] + 2*Lambda[1] -   Lambda[2],
```

```
                2:                 -Lambda[1] + 2*Lambda[2] -   Lambda[3],
                3:  -Lambda[0]                -   Lambda[2] + 2*Lambda[3]}
```

For infinite types, the Cartan matrix is singular, and therefore the embedding of the root lattice is not faithful:

```
sage: sum(Q.simple_roots())
0
```

In particular, the null root is zero:

```
sage: Q.null_root()
0
```

This can be compensated by extending the basis of the weight space and slightly deforming the simple roots to make them linearly independent, without affecting the scalar product with the coroots. This feature is currently only implemented for affine types. In that case, if `extended` is set, then the basis of the weight space is extended by an element δ:

```
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended = True); Q
Extended weight lattice of the Root system of type ['A', 3, 1]
sage: Q.basis().keys()
{0, 1, 2, 3, 'delta'}
```

And the simple root α_0 associated to the special node is deformed as follows:

```
sage: Q.simple_roots()
Finite family {0: 2*Lambda[0] -   Lambda[1]                -   Lambda[3] + delta,
               1:  -Lambda[0] + 2*Lambda[1] -   Lambda[2],
               2:                 -Lambda[1] + 2*Lambda[2] -   Lambda[3],
               3:  -Lambda[0]                -   Lambda[2] + 2*Lambda[3]}
```

Now, the null root is nonzero:

```
sage: Q.null_root()
delta
```

Warning: By a slight notational abuse, the extra basis element used to extend the fundamental weights is called `\delta` in the current implementation. However, in the literature, `\delta` usually denotes instead the null root. Most of the time, those two objects coincide, but not for type BC (aka. $A_{2n}^{(2)}$). Therefore we currently have:

```
sage: Q = RootSystem(["A",4,2]).weight_lattice(extended=True)
sage: Q.simple_root(0)
2*Lambda[0] - Lambda[1] + delta
sage: Q.null_root()
2*delta
```

whereas, with the standard notations from the literature, one would expect to get respectively $2\Lambda_0-\Lambda_1+1/2\delta$ and δ.
Other than this notational glitch, the implementation remains correct for type BC.
The notations may get improved in a subsequent version, which might require changing the index of the extra basis element. To guarantee backward compatibility in code not included in Sage, it is recommended to use the following idiom to get that index:

```
sage: F = Q.basis_extension(); F
Finite family {'delta': delta}
sage: index = F.keys()[0]; index
'delta'
```

Then, for example, the coefficient of an element of the extended weight lattice on that basis element can be recovered with:

```
sage: Q.null_root()[index]
2
```

TESTS:

```
sage: for ct in CartanType.samples(crystallographic=True)+[CartanType(["A",2],["C",5,1])]:
...       TestSuite(ct.root_system().weight_lattice()).run()
...       TestSuite(ct.root_system().weight_space()).run()
sage: for ct in CartanType.samples(affine=True):
...       if ct.is_implemented():
...           P = ct.root_system().weight_space(extended=True)
...           TestSuite(P).run()
```

Element
alias of WeightSpaceElement

basis_extension()
Return the basis elements used to extend the fundamental weights

EXAMPLES:

```
sage: Q = RootSystem(["A",3,1]).weight_lattice()
sage: Q.basis_extension()
Family ()

sage: Q = RootSystem(["A",3,1]).weight_lattice(extended=True)
sage: Q.basis_extension()
Finite family {'delta': delta}
```

This method is irrelevant for finite types:

```
sage: Q = RootSystem(["A",3]).weight_lattice()
sage: Q.basis_extension()
Family ()
```

fundamental_weight(i)

Returns the i-th fundamental weight

INPUT:

- i – an element of the index set or "delta"

By a slight notational abuse, for an affine type this method also accepts "delta" as input, and returns the image of δ of the extended weight lattice in this realization.

EXAMPLES:

```
sage: Q = RootSystem(["A",3]).weight_lattice()
sage: Q.fundamental_weight(1)
Lambda[1]

sage: Q = RootSystem(["A",3,1]).weight_lattice(extended=True)
sage: Q.fundamental_weight(1)
Lambda[1]
sage: Q.fundamental_weight("delta")
delta
```

is_extended()

Returns whether this is an extended weight lattice

EXAMPLES:

```
sage: RootSystem(["A",3,1]).weight_lattice().is_extended()
False
sage: RootSystem(["A",3,1]).weight_lattice(extended=True).is_extended()
True
```

simple_root(j)

Returns the j^{th} simple root

EXAMPLES:

```
sage: L = RootSystem(["C",4]).weight_lattice()
sage: L.simple_root(3)
-Lambda[2] + 2*Lambda[3] - Lambda[4]
```

Its coefficients are given by the corresponding column of the Cartan matrix:

```
sage: L.cartan_type().cartan_matrix()[:,2]
[ 0]
[-1]
[ 2]
[-1]
```

Here are all simple roots:

```
sage: L.simple_roots()
Finite family {1:  2*Lambda[1]   - Lambda[2],
               2:   -Lambda[1] + 2*Lambda[2]   - Lambda[3],
               3:   -Lambda[2] + 2*Lambda[3]   - Lambda[4],
               4:               -2*Lambda[3] + 2*Lambda[4]}
```

For the extended weight lattice of an affine type, the simple root associated to the special node is deformed by adding δ, where δ is the null root:

```
sage: L = RootSystem(["C",4,1]).weight_lattice(extended=True)
sage: L.simple_root(0)
2*Lambda[0] - 2*Lambda[1] + delta
```

In fact δ is really $1/a_0$ times the null root (see the discussion in WeightSpace) but this only makes a difference in type BC:

```
sage: L = RootSystem(CartanType(["BC",4,2])).weight_lattice(extended=True)
sage: L.simple_root(0)
2*Lambda[0] - Lambda[1] + delta
sage: L.null_root()
2*delta
```

See also:

- simple_root()
- CartanType.col_annihilator()

to_ambient_space_morphism()

The morphism from self to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A',2]).root_system().weight_lattice().to_ambient_space_morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To:   Ambient space of the Root system of type ['A', 2]
```

Warning: Implemented only for finite Cartan type.

class sage.combinat.root_system.weight_space.**WeightSpaceElement**(M, x)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

is_dominant()

Checks whether an element in the weight space lies in the positive cone spanned by the basis elements (fundamental weights).

EXAMPLES:

```
sage: W = RootSystem(['A',3]).weight_space()
sage: Lambda = W.basis()
sage: w = Lambda[1]+Lambda[3]
sage: w.is_dominant()
True
sage: w = Lambda[1]-Lambda[2]
```

```
sage: w.is_dominant()
False
```

In the extended affine weight lattice, 'delta' is orthogonal to the positive coroots, so adding or subtracting it should not effect dominance

```
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=true)
sage: Lambda = P.fundamental_weights()
sage: delta = P.null_root()
sage: w = Lambda[1]-delta
sage: w.is_dominant()
True
```

scalar(*lambdacheck*)

The canonical scalar product between the weight lattice and the coroot lattice.

Todo

- merge with_apply_multi_module_morphism
- allow for any root space / lattice
- define properly the return type (depends on the base rings of the two spaces)
- make this robust for extended weight lattices (i might be "delta")

EXAMPLES:

```
sage: L = RootSystem(["C",4,1]).weight_lattice()
sage: Lambda     = L.fundamental_weights()
sage: alphacheck = L.simple_coroots()
sage: Lambda[1].scalar(alphacheck[1])
1
sage: Lambda[1].scalar(alphacheck[2])
0
```

The fundamental weights and the simple coroots are dual bases:

```
sage: matrix([ [ Lambda[i].scalar(alphacheck[j])
...              for i in L.index_set() ]
...            for j in L.index_set() ])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

Note that the scalar product is not yet implemented between the weight space and the coweight space; in any cases, that won't be the job of this method:

```
sage: R = RootSystem(["A",3])
sage: alpha = R.weight_space().roots()
sage: alphacheck = R.coweight_space().roots()
sage: alpha[1].scalar(alphacheck[1])
Traceback (most recent call last):
...
ValueError: -Lambdacheck[1] + 2*Lambdacheck[2] - Lambdacheck[3] is not in the coroot space
```

to_ambient()

Maps `self` to the ambient space.

EXAMPLES:

```
sage: mu = CartanType(['B',2]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2]
sage: mu.to_ambient()
(3, 1)
```

..warning:

```
Only implemented in finite Cartan type.
Does not work for coweight lattices because there is no implemented map
from the coweight lattice to the ambient space.
```

to_weight_space()

Map `self` to the weight space.

Since $self.parent()$ is the weight space, this map just returns `self`. This overrides the generic method in $WeightSpaceRealizations$.

EXAMPLES:

```
sage: mu = CartanType(['A',2]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2]
sage: mu.to_weight_space()
2*Lambda[1] + 2*Lambda[2]
```

5.1.238 Weyl Character Rings

class sage.combinat.root_system.weyl_characters.**WeightRing**(*parent*, *prefix*)

Bases: sage.combinat.free_module.CombinatorialFreeModule

The weight ring, which is the group algebra over a weight lattice.

A Weyl character may be regarded as an element of the weight ring. In fact, an element of the weight ring is an element of the `Weyl character ring` if and only if it is invariant under the action of the Weyl group.

The advantage of the weight ring over the Weyl character ring is that one may conduct calculations in the weight ring that involve sums of weights that are not Weyl group invariant.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: wd = prod(a2(x/2)-a2(-x/2) for x in a2.space().positive_roots()); wd
a2(-1,1,0) - a2(-1,0,1) - a2(1,-1,0) + a2(1,0,-1) + a2(0,-1,1) - a2(0,1,-1)
sage: chi = A2([5,3,0]); chi
A2(5,3,0)
sage: a2(chi)
a2(1,2,5) + 2*a2(1,3,4) + 2*a2(1,4,3) + a2(1,5,2) + a2(2,1,5)
+ 2*a2(2,2,4) + 3*a2(2,3,3) + 2*a2(2,4,2) + a2(2,5,1) + 2*a2(3,1,4)
+ 3*a2(3,2,3) + 3*a2(3,3,2) + 2*a2(3,4,1) + a2(3,5,0) + a2(3,0,5)
+ 2*a2(4,1,3) + 2*a2(4,2,2) + 2*a2(4,3,1) + a2(4,4,0) + a2(4,0,4)
+ a2(5,1,2) + a2(5,2,1) + a2(5,3,0) + a2(5,0,3) + a2(0,3,5)
+ a2(0,4,4) + a2(0,5,3)
sage: a2(chi)*wd
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
sage: sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().weyl_group())
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
sage: a2(chi)*wd == sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().we
True
```

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

A class for weight ring elements.

cartan_type()

Return the Cartan type.

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2([0,1,0]).cartan_type()
['A', 2]
```

character()

Assuming that `self` is invariant under the Weyl group, this will express it as a linear combination of characters. If `self` is not Weyl group invariant, this method will not terminate.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: W = a2.space().weyl_group()
sage: mu = a2(2,1,0)
sage: nu = sum(mu.weyl_group_action(w) for w in W) ; nu
a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,2,1)
sage: nu.character()
-2*A2(1,1,1) + A2(2,1,0)
```

demazure(*w*, *debug=False*)

Return the result of applying the Demazure operator ∂_w to `self`.

INPUT:

- `w` – a Weyl group element, or its reduced word

If $w = s_i$ is a simple reflection, the operation ∂_w sends the weight λ to

$$\frac{\lambda - s_i \cdot \lambda + \alpha_i}{1 + \alpha_i}$$

where the numerator is divisible the denominator in the weight ring. This is extended by multiplicativity to all w in the Weyl group.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style="coroots")
sage: b2=WeightRing(B2)
sage: b2(1,0).demazure([1])
b2(1,0) + b2(-1,2)
sage: b2(1,0).demazure([2])
b2(1,0)
sage: r=b2(1,0).demazure([1,2]); r
b2(1,0) + b2(-1,2)
sage: r.demazure([1])
b2(1,0) + b2(-1,2)
sage: r.demazure([2])
b2(0,0) + b2(1,0) + b2(1,-2) + b2(-1,2)
```

demazure_lusztig(*i*, *v*)

Return the result of applying the Demazure-Lusztig operator T_i to `self`.

INPUT:

- `i` – an element of the index set (or a reduced word or Weyl group element)

•v – an element of the base ring

If R is the parent WeightRing, the Demazure-Lusztig operator T_i is the linear map $R \to R$ that sends (for a weight λ) $R(\lambda)$ to

$$(R(\alpha_i) - 1)^{-1}\big(R(\lambda) - R(s_i\lambda) - v(R(\lambda) - R(\alpha_i + s_i\lambda))\big)$$

where the numerator is divisible by the denominator in R. The Demazure-Lusztig operators give a representation of the Iwahori–Hecke algebra associated to the Weyl group. See

•Lusztig, Equivariant K-theory and representations of Hecke algebras, Proc. Amer. Math. Soc. 94 (1985), no. 2, 337-342.

•Cherednik, *Nonsymmetric Macdonald polynomials*. IMRN 10, 483-515 (1995).

In the examples, we confirm the braid and quadratic relations for type B_2.

EXAMPLES:

```
sage: P.<v> = PolynomialRing(QQ)
sage: B2 = WeylCharacterRing("B2",style="coroots",base_ring=P); b2 = B2.ambient()
sage: def T1(f) : return f.demazure_lusztig(1,v)
sage: def T2(f) : return f.demazure_lusztig(2,v)
sage: T1(T2(T1(T2(b2(1,-1)))))
(v^2-v)*b2(0,-1) + v^2*b2(-1,1)
sage: [T1(T1(f))==(v-1)*T1(f)+v*f for f in [b2(0,0), b2(1,0), b2(2,3)]]
[True, True, True]
sage: [T1(T2(T1(T2(b2(i,j))))) == T2(T1(T2(T1(b2(i,j))))) for i in [-2..2] for j in [-1,
[True, True, True, True, True, True, True, True, True, True]
```

Instead of an index i one may use a reduced word or Weyl group element:

```
sage: b2(1,0).demazure_lusztig([2,1],v)==T2(T1(b2(1,0)))
True
sage: W = B2.space().weyl_group(prefix="s")
sage: [s1,s2]=W.simple_reflections()
sage: b2(1,0).demazure_lusztig(s2*s1,v)==T2(T1(b2(1,0)))
True
```

scale(*k*)

Multiplies a weight by k. The operation is extended by linearity to the weight ring.

INPUT:

•k – a nonzero integer

EXAMPLES:

```
sage: g2 = WeylCharacterRing("G2",style="coroots").ambient()
sage: g2(2,3).scale(2)
g2(4,6)
```

shift(*mu*)

Add μ to any weight. Extended by linearity to the weight ring.

INPUT:

•mu – a weight

EXAMPLES:

```
sage: g2 = WeylCharacterRing("G2",style="coroots").ambient()
sage: [g2(1,2).shift(fw) for fw in g2.fundamental_weights()]
[g2(2,2), g2(1,3)]
```

weyl_group_action(*w*)

Return the action of the Weyl group element `w` on `self`.

EXAMPLES:

```
sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: L = g2.space()
sage: [fw1, fw2] = L.fundamental_weights()
sage: sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-2) + 2*g2(2,-1,-
```

WeightRing.**cartan_type**()

Return the Cartan type.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: WeightRing(A2).cartan_type()
['A', 2]
```

WeightRing.**fundamental_weights**()

Return the fundamental weights.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

WeightRing.**one_basis**()

Return the index of 1.

EXAMPLES:

```
sage: A3=WeylCharacterRing("A3")
sage: WeightRing(A3).one_basis()
(0, 0, 0, 0)
sage: WeightRing(A3).one()
a3(0,0,0,0)
```

WeightRing.**parent**()

Return the parent Weyl character ring.

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: a2=WeightRing(A2)
sage: a2.parent()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: a2.parent() == A2
True
```

WeightRing.**positive_roots**()

Return the positive roots.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

WeightRing.**product_on_basis**(a, b)

Return the product of basis elements indexed by `a` and `b`.

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: a2=WeightRing(A2)
```

```
sage: a2(1,0,0) * a2(0,1,0) # indirect doctest
a2(1,1,0)
```

WeightRing.**simple_roots**()
Return the simple roots.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

WeightRing.**some_elements**()
Return some elements of `self`.

EXAMPLES:

```
sage: A3=WeylCharacterRing("A3")
sage: a3=WeightRing(A3)
sage: a3.some_elements()
[a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

WeightRing.**space**()
Return the weight space realization associated to `self`.

EXAMPLES:

```
sage: E8 = WeylCharacterRing(['E',8])
sage: e8 = WeightRing(E8)
sage: e8.space()
Ambient space of the Root system of type ['E', 8]
```

WeightRing.**weyl_character_ring**()
Return the parent Weyl Character Ring. A synonym for `self.parent()`.

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: a2=WeightRing(A2)
sage: a2.weyl_character_ring()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

WeightRing.**wt_repr**(*wt*)
Return a string representing the irreducible character with highest weight vector `wt`. Uses coroot notation if the associated Weyl character ring is defined with `style="coroots"`.

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0,-1)', 'g2(2,-1,-1)']
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0)', 'g2(0,1)']
```

class sage.combinat.root_system.weyl_characters.**WeylCharacterRing**(*ct*, *base_ring=Integer Ring*, *prefix=None*, *style='lattice'*)

Bases: sage.combinat.free_module.CombinatorialFreeModule

A class for rings of Weyl characters.

Let K be a compact Lie group, which we assume is semisimple and simply-connected. Its complexified Lie algebra L is the Lie algebra of a complex analytic Lie group G. The following three categories are equivalent: finite-dimensional representations of K; finite-dimensional representations of L; and finite-dimensional analytic representations of G. In every case, there is a parametrization of the irreducible representations by their highest weight vectors. For this theory of Weyl, see (for example):

- Adams, *Lectures on Lie groups*
- Broecker and Tom Dieck, *Representations of Compact Lie groups*
- Bump, *Lie Groups*
- Fulton and Harris, *Representation Theory*
- Goodman and Wallach, *Representations and Invariants of the Classical Groups*
- Hall, *Lie Groups, Lie Algebras and Representations*
- Humphreys, *Introduction to Lie Algebras and their representations*
- Procesi, *Lie Groups*
- Samelson, *Notes on Lie Algebras*
- Varadarajan, *Lie groups, Lie algebras, and their representations*
- Zhelobenko, *Compact Lie Groups and their Representations*.

Computations that you can do with these include computing their weight multiplicities, products (thus decomposing the tensor product of a representation into irreducibles) and branching rules (restriction to a smaller group).

There is associated with K, L or G as above a lattice, the weight lattice, whose elements (called weights) are characters of a Cartan subgroup or subalgebra. There is an action of the Weyl group W on the lattice, and elements of a fixed fundamental domain for W, the positive Weyl chamber, are called dominant. There is for each representation a unique highest dominant weight that occurs with nonzero multiplicity with respect to a certain partial order, and it is called the highest weight vector.

EXAMPLES:

```
sage: L = RootSystem("A2").ambient_space()
sage: [fw1,fw2] = L.fundamental_weights()
sage: R = WeylCharacterRing(['A',2], prefix="R")
sage: [R(1),R(fw1),R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

Here `R(1)`, `R(fw1)`, and `R(fw2)` are irreducible representations with highest weight vectors 0, Λ_1, and Λ_2 respecitively (the first two fundamental weights).

For type A (also G_2, F_4, E_6 and E_7) we will take as the weight lattice not the weight lattice of the semisimple group, but for a larger one. For type A, this means we are concerned with the representation theory of $K = U(n)$ or $G = GL(n, \mathbf{C})$ rather than $SU(n)$ or $SU(n, \mathbf{C})$. This is useful since the representation theory of $GL(n)$ is ubiquitous, and also since we may then represent the fundamental weights (in `sage.combinat.root_system.root_system`) by vectors with integer entries. If you are only interested in $SL(3)$, say, use `WeylCharacterRing(['A',2])` as above but be aware that `R([a,b,c])` and `R([a+1,b+1,c+1])` represent the same character of $SL(3)$ since `R([1,1,1])` is the determinant.

For more information, see the thematic tutorial *Lie Methods and Related Combinatorics in Sage*, available at:

http://www.sagemath.org/doc/thematic_tutorials/lie.html

class Element(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

A class for Weyl characters.

adams_operation(*r*)

Return the r-th Adams operation of self.

INPUT:

- r – a positive integer

This is a virtual character, whose weights are the weights of self, each multiplied by r.

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operation(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

branch(*S*, *rule='default'*)

Return the restriction of the character to the subalgebra. If no rule is specified, we will try to specify one.

INPUT:

- S – a Weyl character ring for a Lie subgroup or subalgebra
- rule – a branching rule

See branch_weyl_character() for more information about branching rules.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: A2 = WeylCharacterRing(['A',2])
sage: [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2([1,0,0]).cartan_type()
['A', 2]
```

degree()

The degree of self, that is, the dimension of module.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]
```

exterior_power(*k*)

Return the k-th exterior power of self.

INPUT:

- k – a nonnegative integer

The algorithm is based on the identity $ke_k = \sum_{r=1}^{k}(-1)^{k-1}p_k e_{k-r}$ relating the power-sum and elementary symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation self, the e_k become exterior powers and the p_k become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

```
sage: B3=WeylCharacterRing("B3",style="coroots")
sage: spin=B3(0,0,1)
sage: spin.exterior_power(6)
B3(1,0,0) + B3(0,1,0)
```

exterior_square()

Return the exterior square of the character.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: A2(1,0).exterior_square()
A2(0,1)
```

frobenius_schur_indicator()

Return:

- 1 if the representation is real (orthogonal)
- -1 if the representation is quaternionic (symplectic)
- 0 if the representation is complex (not self dual)

The Frobenius-Schur indicator of a character χ of a compact group G is the Haar integral over the group of $\chi(g^2)$. Its value is 1, -1 or 0. This method computes it for irreducible characters of compact Lie groups by checking whether the symmetric and exterior square characters contain the trivial character.

Todo

Try to compute this directly without actually calculating the full symmetric and exterior squares.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style="coroots")
sage: B2(1,0).frobenius_schur_indicator()
 1
sage: B2(0,1).frobenius_schur_indicator()
 -1
```

inner_product(*other*)

Compute the inner product with another character.

The irreducible characters are an orthonormal basis with respect to the usual inner product of characters, interpreted as functions on a compact Lie group, by Schur orthogonality.

INPUT:

- `other` – another character

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: [f1,f2]=A2.fundamental_weights()
sage: r1 = A2(f1)*A2(f2); r1
A2(1,1,1) + A2(2,1,0)
sage: r2 = A2(f1)^3; r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
sage: r1.inner_product(r2)
3
```

invariant_degree()

Return the multiplicity of the trivial representation in `self`.

Multiplicities of other irreducibles may be obtained using `multiplicity()`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: rep = A2(1,0)^2*A2(0,1)^2; rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
sage: rep.invariant_degree()
2
```

is_irreducible()

Return whether `self` is an irreducible character.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).is_irreducible() for x in B3.fundamental_weights()]
[True, True, True]
sage: sum(B3(x) for x in B3.fundamental_weights()).is_irreducible()
False
```

multiplicity(*other*)

Return the multiplicity of the irreducible `other` in `self`.

INPUT:

- `other` – an irreducible character

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style="coroots")
sage: rep = B2(1,1)^2; rep
B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) + B2(2,2)
sage: rep.multiplicity(B2(0,2))
2
```

symmetric_power(k)

Return the k-th symmetric power of `self`.

INPUT:

- k – a nonnegative integer

The algorithm is based on the identity $kh_k = \sum_{r=1}^{k} p_k h_{k-r}$ relating the power-sum and complete symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation `self`, the h_k become symmetric powers and the p_k become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

```
sage: B3=WeylCharacterRing("B3",style="coroots")
sage: spin=B3(0,0,1)
sage: spin.symmetric_power(6)
B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
```

symmetric_square()

Return the symmetric square of the character.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: A2(1,0).symmetric_square()
A2(2,0)
```

weight_multiplicities()

Produce the dictionary of weight multiplicities for the Weyl character `self`. The character does not have to be irreducible.

EXAMPLES:

```
sage: from pprint import pprint
sage: B2=WeylCharacterRing("B2",style="coroots")
```

```
sage: pprint(B2(0,1).weight_multiplicities())
{(-1/2, -1/2): 1, (-1/2, 1/2): 1, (1/2, -1/2): 1, (1/2, 1/2): 1}
```

WeylCharacterRing.**adjoint_representation**()

Returns the adjoint representation as an element of the WeylCharacterRing".

EXAMPLES:

```
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2.adjoint_representation()
G2(0,1)
```

WeylCharacterRing.**ambient**()

Returns the weight ring of `self`.

EXAMPLES:

```
sage: WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer Ring coefficient
```

WeylCharacterRing.**base_ring**()

Return the base ring of `self`.

EXAMPLES:

```
sage: R = WeylCharacterRing(['A',3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

WeylCharacterRing.**cartan_type**()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: WeylCharacterRing("A2").cartan_type()
['A', 2]
```

WeylCharacterRing.**char_from_weights**(*mdict*)

Construct a Weyl character from an invariant linear combination of weights.

INPUT:

- `mdict` – a dictionary mapping weights to coefficients, and representing a linear combination of weights which shall be invariant under the action of the Weyl group

OUTPUT: the corresponding Weyl character

EXAMPLES:

```
sage: from pprint import pprint
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: d = dict([(x,1) for x in v.orbit()]); pprint(d)
{(1, 3, 0): 1,
 (1, 0, 3): 1,
 (3, 1, 0): 1,
 (3, 0, 1): 1,
 (0, 1, 3): 1,
 (0, 3, 1): 1}
sage: A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

WeylCharacterRing.**demazure_character**(*hwv*, *word*, *debug=False*)

Compute the Demazure character.

INPUT:

- hwv – a (usually dominant) weight
- word – a Weyl group word

Produces the Demazure character with highest weight hwv and word as an element of the weight ring. Only available if style="coroots". The Demazure operators are also available as methods of WeightRing elements, and as methods of crystals. Given a CrystalOfTableaux with given highest weight vector, the Demazure method on the crystal will give the equivalent of this method, except that the Demazure character of the crystal is given as a sum of monomials instead of an element of the WeightRing.

See WeightRing.Element.demazure() and sage.categories.classical_crystals.ClassicalCrys

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: h=sum(A2.fundamental_weights()); h
(2, 1, 0)
sage: A2.demazure_character(h,word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
sage: A2.demazure_character((1,1),word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
```

WeylCharacterRing.**dot_reduce**(*a*)

Auxiliary function for product_on_basis().

Return a pair $[\epsilon, b]$ where b is a dominant weight and ϵ is 0, 1 or -1. To describe b, let w be an element of the Weyl group such that $w(a+\rho)$ is dominant. If $w(a+\rho)-\rho$ is dominant, then ϵ is the sign of w and b is $w(a+\rho)-\rho$. Otherwise, ϵ is zero.

INPUT:

- a – a weight

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: weights = sorted(A2(2,1,0).weight_multiplicities().keys(), key=str); weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: [A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0, 0)], [0, (0, 0
```

WeylCharacterRing.**dynkin_diagram**()

Return the Dynkin diagram of self.

EXAMPLES:

```
sage: WeylCharacterRing("E7").dynkin_diagram()
        O 2
        |
        |
O---O---O---O---O---O
1   3   4   5   6   7
E7
```

WeylCharacterRing.**extended_dynkin_diagram**()

Return the extended Dynkin diagram, which is the Dynkin diagram of the corresponding untwisted affine type.

EXAMPLES:

```
sage: WeylCharacterRing("E7").extended_dynkin_diagram()
            O 2
            |
            |
O---O---O---O---O---O---O
0   1   3   4   5   6   7
E7~
```

WeylCharacterRing.**fundamental_weights**()

Return the fundamental weights.

EXAMPLES:

```
sage: WeylCharacterRing("G2").fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

WeylCharacterRing.**highest_root**()

Return the highest_root.

EXAMPLES:

```
sage: WeylCharacterRing("G2").highest_root()
 (2, -1, -1)
```

WeylCharacterRing.**irr_repr**(*hwv*)

Return a string representing the irreducible character with highest weight vector `hwv`.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3")
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(1,1,0)', 'B3(1/2,1/2,1/2)']
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(0,1,0)', 'B3(0,0,1)']
```

WeylCharacterRing.**lift**()

The embedding of `self` into its weight ring.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2.lift
Generic morphism:
  From: The Weyl Character Ring of Type A2 with Integer Ring coefficients
  To:   The Weight ring attached to The Weyl Character Ring of Type A2 with Integer Ring coe

sage: x = -A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2.lift(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

As a shortcut, you may also do:

```
sage: x.lift()
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

Or even:

```
sage: a2 = WeightRing(A2)
sage: a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

WeylCharacterRing.**lift_on_basis**(*irr*)

Expand the basis element indexed by the weight `irr` into the weight ring of `self`.

INPUT:

- `irr` – a dominant weight

This is used to implement `lift()`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([2,1,0]); v
(2, 1, 0)
sage: A2.lift_on_basis(v)
2*a2(1,1,1) + a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,2,1)
```

This is consistent with the analoguous calculation with symmetric Schur functions:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
```

WeylCharacterRing.**maximal_subgroup**(*ct*)

INPUT:

- `ct` – the Cartan type of a maximal subgroup of self.

Returns a branching rule. In rare cases where there is more than one maximal subgroup (up to outer automorphisms) with the given Cartan type, the function returns a list of branching rules.

EXAMPLES:

```
sage: WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2
sage: WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]
```

For more information, see the related method `maximal_subgroups()`.

WeylCharacterRing.**maximal_subgroups**()

This method is only available if the Cartan type of self is irreducible and of rank no greater than 8. This method produces a list of the maximal subgroups of self, up to (possibly outer) automorphisms. Each line in the output gives the Cartan type of a maximal subgroup followed by a command that creates the branching rule.

EXAMPLES:

```
sage: WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")
```

Note that there are other embeddings of (for example A_2 into E_6 as nonmaximal subgroups. These embeddings may be constructed by composing branching rules through various subgroups.

Once you know which maximal subgroup you are interested in, to create the branching rule, you may either paste the command to the right of the colon from the above output onto the command line, or alternatively invoke the related method `maximal_subgroup()`:

```
sage: branching_rule("E6","G2","miscellaneous")
miscellaneous branching rule E6 => G2
sage: WeylCharacterRing("E6").maximal_subgroup("G2")
miscellaneous branching rule E6 => G2
```

It is believed that the list of maximal subgroups is complete, except that some subgroups may be not be invariant under outer automorphisms. It is reasonable to want a list of maximal subgroups that is complete up to conjugation, but to obtain such a list you may have to apply outer automorphisms. The group of outer automorphisms modulo inner automorphisms is isomorphic to the group of symmetries of the Dynkin diagram, and these are available as branching rules. The following example shows that while a branching rule from D_4 to $A_1 imes C_2$ is supplied, another different one may be obtained by composing it with the triality automorphism of D_4:

```
sage: [D4,A1xC2]=[WeylCharacterRing(x,style="coroots") for x in ["D4","A1xC2"]]
sage: fw = D4.fundamental_weights()
sage: b = D4.maximal_subgroup("A1xC2")
sage: [D4(fw).branch(A1xC2,rule=b) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(0,0,1)]
sage: b1 = branching_rule("D4","D4","triality")*b
sage: [D4(fw).branch(A1xC2,rule=b1) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(2,0,0) + A1xC2(0,0,1),
A1xC2(1,1,0)]
```

WeylCharacterRing.**one_basis**()

Return the index of 1 in `self`.

EXAMPLES:

```
sage: WeylCharacterRing("A3").one_basis()
(0, 0, 0, 0)
sage: WeylCharacterRing("A3").one()
A3(0,0,0,0)
```

WeylCharacterRing.**positive_roots**()

Return the positive roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

WeylCharacterRing.**product_on_basis**(a, b)

Compute the tensor product of two irreducible representations `a` and `b`.

EXAMPLES:

```
sage: D4 = WeylCharacterRing(['D',4])
sage: spin_plus = D4(1/2,1/2,1/2,1/2)
sage: spin_minus = D4(1/2,1/2,1/2,-1/2)
sage: spin_plus * spin_minus # indirect doctest
D4(1,0,0,0) + D4(1,1,1,0)
sage: spin_minus * spin_plus
```

```
D4(1,0,0,0) + D4(1,1,1,0)
```

Uses the Brauer-Klimyk method.

WeylCharacterRing.**rank**()
Return the rank.

EXAMPLES:

```
sage: WeylCharacterRing("G2").rank()
2
```

WeylCharacterRing.**retract**()
The partial inverse map from the weight ring into `self`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: A2.retract
Generic morphism:
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with Integer Ring coe
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients

sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
sage: A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

The input should be invariant:

```
sage: A2.retract(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

As a shortcut, you may use conversion:

```
sage: A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

WeylCharacterRing.**simple_coroots**()
Return the simple coroots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
```

WeylCharacterRing.**simple_roots**()
Return the simple roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

WeylCharacterRing.**some_elements**()

Return some elements of `self`.

EXAMPLES:

```
sage: WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]
```

WeylCharacterRing.**space**()

Return the weight space associated to `self`.

EXAMPLES:

```
sage: WeylCharacterRing(['E',8]).space()
Ambient space of the Root system of type ['E', 8]
```

sage.combinat.root_system.weyl_characters.**irreducible_character_freudenthal**(*hwv*, *debug=False*)

Return the dictionary of multiplicities for the irreducible character with highest weight λ.

The weight multiplicities are computed by the Freudenthal multiplicity formula. The algorithm is based on recursion relation that is stated, for example, in Humphrey's book on Lie Algebras. The multiplicities are invariant under the Weyl group, so to compute them it would be sufficient to compute them for the weights in the positive Weyl chamber. However after some testing it was found to be faster to compute every weight using the recursion, since the use of the Weyl group is expensive in its current implementation.

INPUT:

- `hwv` – a dominant weight in a weight lattice.
- `L` – the ambient space

EXAMPLES:

```
sage: from pprint import pprint
sage: pprint(WeylCharacterRing("A2")(2,1,0).weight_multiplicities()) # indirect doctest
{(1, 1, 1): 2, (1, 2, 0): 1, (1, 0, 2): 1, (2, 1, 0): 1,
 (2, 0, 1): 1, (0, 1, 2): 1, (0, 2, 1): 1}
```

5.1.239 Weyl Groups

AUTHORS:

- Daniel Bump (2008): initial version
- Mike Hansen (2008): initial version
- Anne Schilling (2008): initial version
- Nicolas Thiery (2008): initial version
- Volker Braun (2013): LibGAP-based matrix groups

EXAMPLES:

More examples on Weyl Groups should be added here...

The Cayley graph of the Weyl Group of type ['A', 3]:

```
sage: w = WeylGroup(['A',3])
sage: d = w.cayley_graph(); d
Digraph on 24 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03)
```

The Cayley graph of the Weyl Group of type ['D', 4]:

```
sage: w = WeylGroup(['D',4])
sage: d = w.cayley_graph(); d
Digraph on 192 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03) #long time (less than one minut
```

class sage.combinat.root_system.weyl_group.**ClassicalWeylSubgroup**(*domain*, *prefix*)

Bases: sage.combinat.root_system.weyl_group.WeylGroup_gens

A class for Classical Weyl Subgroup of an affine Weyl Group

EXAMPLES:

```
sage: G = WeylGroup(["A",3,1]).classical()
sage: G
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group acting on the root s
sage: G.category()
Category of finite weyl groups
sage: G.cardinality()
24
sage: G.index_set()
(1, 2, 3)
sage: TestSuite(G).run()
```

TESTS:

```
sage: from sage.combinat.root_system.weyl_group import ClassicalWeylSubgroup
sage: H = ClassicalWeylSubgroup(RootSystem(["A", 3, 1]).root_space(), prefix=None)
sage: H is G
True
```

Caveat: the interface is likely to change. The current main application is for plots.

Todo

implement:

- Parabolic subrootsystems
- Parabolic subgroups with a set of nodes as argument

---

cartan_type()

EXAMPLES:

```
sage: WeylGroup(['A',3,1]).classical().cartan_type()
['A', 3]
sage: WeylGroup(['A',3,1]).classical().index_set()
(1, 2, 3)
```

Note: won't be needed, once the lattice will be a parabolic sub root system

simple_reflections()

EXAMPLES:

```
sage: WeylGroup(['A',2,1]).classical().simple_reflections()
Finite family {1: [ 1  0  0]
                  [ 1 -1  1]
                  [ 0  0  1],
               2: [ 1  0  0]
                  [ 0  1  0]
                  [ 1  1 -1]}
```

Note: won't be needed, once the lattice will be a parabolic sub root system

weyl_group (*prefix='hereditary'*)

Return the Weyl group associated to the parabolic subgroup.

EXAMPLES:

```
sage: WeylGroup(['A',4,1]).classical().weyl_group()
Weyl Group of type ['A', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['C',4,1]).classical().weyl_group()
Weyl Group of type ['C', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['E',8,1]).classical().weyl_group()
Weyl Group of type ['E', 8, 1] (as a matrix group acting on the root space)
```

sage.combinat.root_system.weyl_group.**WeylGroup** (*x*, *prefix=None*)

Returns the Weyl group of the root system defined by the Cartan type (or matrix) `ct`.

INPUT:

- `x` - a root system or a Cartan type (or matrix)

OPTIONAL:

- `prefix` – changes the representation of elements from matrices to products of simple reflections

EXAMPLES:

The following constructions yield the same result, namely a weight lattice and its corresponding Weyl group:

```
sage: G = WeylGroup(['F',4])
sage: L = G.domain()
```

or alternatively and equivalently:

```
sage: L = RootSystem(['F',4]).ambient_space()
sage: G = L.weyl_group()
sage: W = WeylGroup(L)
```

Either produces a weight lattice, with access to its roots and weights.

```
sage: G = WeylGroup(['F',4])
sage: G.order()
1152
sage: [s1,s2,s3,s4] = G.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: type(w) == G.element_class
True
sage: w.order()
12
```

```
sage: w.length() # length function on Weyl group
4
```

The default representation of Weyl group elements is as matrices. If you prefer, you may specify a prefix, in which case the elements are represented as products of simple reflections.

```
sage: W=WeylGroup("C3",prefix="s")
sage: [s1,s2,s3]=W.simple_reflections() # lets Sage parse its own output
sage: s2*s1*s2*s3
s1*s2*s3*s1
sage: s2*s1*s2*s3 == s1*s2*s3*s1
True
sage: (s2*s3)^2==(s3*s2)^2
True
sage: (s1*s2*s3*s1).matrix()
[ 0  0 -1]
[ 0  1  0]
[ 1  0  0]

sage: L = G.domain()
sage: fw = L.fundamental_weights(); fw
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
sage: rho = sum(fw); rho
(11/2, 5/2, 3/2, 1/2)
sage: w.action(rho) # action of G on weight lattice
(5, -1, 3, 2)
```

We can also do the same for arbitrary Cartan matrices:

```
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: W = WeylGroup(cm)
sage: W.gens()
(
[-1  5  0]  [ 1  0  0]  [ 1  0  0]
[ 0  1  0]  [ 2 -1  1]  [ 0  1  0]
[ 0  0  1], [ 0  0  1], [ 0  1 -1]
)
sage: s0,s1,s2 = W.gens()
sage: s1*s2*s1
[ 1  0  0]
[ 2  0 -1]
[ 2 -1  0]
sage: s2*s1*s2
[ 1  0  0]
[ 2  0 -1]
[ 2 -1  0]
sage: s0*s1*s0*s2*s0
[ 9  0 -5]
[ 2  0 -1]
[ 0  1 -1]
```

Same Cartan matrix, but with a prefix to display using simple reflections:

```
sage: W = WeylGroup(cm, prefix='s')
sage: s0,s1,s2 = W.gens()
sage: s0*s2*s1
s2*s0*s1
sage: (s1*s2)^3
1
```

```
sage: (s0*s1)^5
s0*s1*s0*s1*s0*s1*s0*s1*s0*s1
sage: s0*s1*s2*s1*s2
s2*s0*s1
sage: s0*s1*s2*s0*s2
s0*s1*s0
```

TESTS:

```
sage: TestSuite(WeylGroup(["A",3])).run()
sage: TestSuite(WeylGroup(["A",3,1])).run()  # long time

sage: W = WeylGroup(['A',3,1])
sage: s = W.simple_reflections()
sage: w = s[0]*s[1]*s[2]
sage: w.reduced_word()
[0, 1, 2]
sage: w = s[0]*s[2]
sage: w.reduced_word()
[2, 0]
sage: W = groups.misc.WeylGroup(['A',3,1])
```

class sage.combinat.root_system.weyl_group.**WeylGroupElement**(*parent*, *g*, *check=False*)

Bases: sage.groups.matrix_gps.group_element.MatrixGroupElement_gap

Class for a Weyl Group elements

action(*v*)

Returns the action of self on the vector v.

EXAMPLES:

```
sage: W = WeylGroup(['A',2])
sage: s = W.simple_reflections()
sage: v = W.domain()([1,0,0])
sage: s[1].action(v)
(0, 1, 0)

sage: W = WeylGroup(RootSystem(['A',2]).root_lattice())
sage: s = W.simple_reflections()
sage: alpha = W.domain().simple_roots()
sage: s[1].action(alpha[1])
-alpha[1]

sage: W=WeylGroup(['A',2,1])
sage: alpha = W.domain().simple_roots()
sage: s = W.simple_reflections()
sage: s[1].action(alpha[1])
-alpha[1]
sage: s[1].action(alpha[0])
alpha[0] + alpha[1]
```

apply_simple_reflection(*i*, *side='right'*)

domain()

Returns the ambient lattice associated with self.

EXAMPLES:

```
sage: W = WeylGroup(['A',2])
sage: s1 = W.simple_reflection(1)
```

```
sage: s1.domain()
Ambient space of the Root system of type ['A', 2]
```

has_descent(*i*, *positive=False*, *side='right'*)

Tests if self has a descent at position i, that is if self is on the strict negative side of the i^{th} simple reflection hyperplane.

If positive is True, tests if it is on the strict positive side instead.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [s[3].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
sage: W = WeylGroup(['A',3,1])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False, False]
sage: [s[0].has_descent(i) for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[1]
sage: [w.has_descent(i) for i in W.domain().index_set()]
[False, True, False, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[2]
sage: [w.has_descent(i) for i in W.domain().index_set()]
[True, False, True, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, True, False]

sage: W = WeylGroup(['A',3])
sage: W.one().has_descent(0)
True
sage: W.w0.has_descent(0)
False
```

has_left_descent(*i*)

Tests if self has a left descent at position i.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_descent(i) for i in W.domain().index_set()]
```

```
[False, False, True]
sage: [s[3].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
```

to_permutation()

A first approximation of to_permutation ...

This assumes types A,B,C,D on the ambient lattice

This further assume that the basis is indexed by 0,1,... and returns a permutation of (5,4,2,3,1) (beuargl), as a tuple

to_permutation_string()

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: s = W.simple_reflections()
sage: (s[1]*s[2]*s[3]).to_permutation_string()
'2341'
```

class sage.combinat.root_system.weyl_group.**WeylGroup_gens**(*domain*, *prefix*)

Bases: sage.misc.cachefunc.ClearCacheOnPickle, sage.structure.unique_representation.Unique
sage.groups.matrix_gps.finitely_generated.FinitelyGeneratedMatrixGroup_gap

EXAMPLES:

```
sage: G = WeylGroup(['B',3])
sage: TestSuite(G).run()
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: W = WeylGroup(cm)
sage: TestSuite(W).run() # long time
```

Element

alias of WeylGroupElement

bruhat_graph(*x*, *y*)

Return the Bruhat graph as a directed graph, with an edge $u \to v$ if and only if $u < v$ in the Bruhat order, and $u = r \cdot v$.

The Bruhat graph $\Gamma(x, y)$, defined if $x \leq y$ in the Bruhat order, has as its vertices the Bruhat interval $\{t | x \leq t \leq y\}$, and as its edges are the pairs (u, v) such that $u = r \cdot v$ where r is a reflection, that is, a conjugate of a simple reflection.

REFERENCES:

Carrell, The Bruhat graph of a Coxeter group, a conjecture of Deodhar, and rational smoothness of Schubert varieties. Algebraic groups and their generalizations: classical methods (University Park, PA, 1991), 53–61, Proc. Sympos. Pure Math., 56, Part 1, Amer. Math. Soc., Providence, RI, 1994.

EXAMPLES:

```
sage: W = WeylGroup("A3", prefix="s")
sage: s1, s2, s3 = W.simple_reflections()
sage: G = W.bruhat_graph(s1*s3, s1*s2*s3*s2*s1); G
Digraph on 10 vertices
```

Check that the graph has the correct number of edges (see trac ticket #17744):

```
sage: len(G.edges())
16
```

cartan_type()
Returns the CartanType associated to self.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.cartan_type()
['F', 4]
```

character_table()
Returns the character table as a matrix

Each row is an irreducible character. For larger tables you may preface this with a command such as gap.eval("SizeScreen([120,40])") in order to widen the screen.

EXAMPLES:

```
sage: WeylGroup(['A',3]).character_table()
CT1

     2  3  2  2  .  3
     3  1  .  .  1  .

       1a 4a 2a 3a 2b

X.1     1 -1 -1  1  1
X.2     3  1 -1  . -1
X.3     2  .  . -1  2
X.4     3 -1  1  . -1
X.5     1  1  1  1  1
```

classical()
If `self` is a Weyl group from an affine Cartan Type, this give the classical parabolic subgroup of `self`.

Caveat: we assume that 0 is a special node of the Dynkin diagram

TODO: extract parabolic subgroup method

EXAMPLES:

```
sage: G = WeylGroup(['A',3,1])
sage: G.classical()
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1]
 (as a matrix group acting on the root space)
sage: WeylGroup(['A',3]).classical()
Traceback (most recent call last):
...
ValueError: classical subgroup only defined for affine types
```

coxeter_matrix()
Return the Coxeter matrix associated to `self`.

EXAMPLES:

```
sage: G = WeylGroup(['A',3])
sage: G.coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
```

domain()
Returns the domain of the element of `self`, that is the root lattice realization on which they act.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.domain()
Ambient space of the Root system of type ['F', 4]
sage: G = WeylGroup(['A',3,1])
sage: G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]
```

from_morphism(*f*)

index_set()

Returns the index set of self.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.index_set()
(1, 2, 3, 4)
sage: G = WeylGroup(['A',3,1])
sage: G.index_set()
(0, 1, 2, 3)
```

long_element_hardcoded()

Returns the long Weyl group element (hardcoded data)

Do we really want to keep it? There is a generic implementation which works in all cases. The hardcoded should have a better complexity (for large classical types), but there is a cache, so does this really matter?

EXAMPLES:

```
sage: types = [ ['A',5],['B',3],['C',3],['D',4],['G',2],['F',4],['E',6] ]
sage: [WeylGroup(t).long_element().length() for t in types]
[15, 9, 9, 12, 6, 24, 36]
sage: all( WeylGroup(t).long_element() == WeylGroup(t).long_element_hardcoded() for t in typ
True
```

morphism_matrix(*f*)

one()

Returns the unit element of the Weyl group

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

reflections()

Return the reflections of `self`.

The reflections of a Coxeter group W are the conjugates of the simple reflections. They are in bijection with the positive roots, for given a positive root, we may have the reflection in the hyperplane orthogonal to it. This method returns a family indexed by the positive roots taking values in the reflections. This requires `self` to be a finite Weyl group.

Note: Prior to trac ticket #20027, the reflections were the keys of the family and the values were the

positive roots.

EXAMPLES:

```
sage: W = WeylGroup("B2", prefix="s")
sage: refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1, (0, 1): s2}
sage: [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]
```

simple_reflection(*i*)

Returns the i^{th} simple reflection.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.simple_reflection(1)
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]
sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflection(1)
[ 1  0  0]
[ 1 -1  1]
[ 0  0  1]
```

simple_reflections()

Returns the simple reflections of self, as a family.

EXAMPLES:

There are the simple reflections for the symmetric group:

```
sage: W=WeylGroup(['A',2])
sage: s = W.simple_reflections(); s
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1], 2: [1 0 0]
[0 0 1]
[0 1 0]}
```

As a special feature, for finite irreducible root systems, s[0] gives the reflection along the highest root:

```
sage: s[0]
[0 0 1]
[0 1 0]
[1 0 0]
```

We now look at some further examples:

```
sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflections()
Finite family {0: [-1  1  1]
[ 0  1  0]
[ 0  0  1], 1: [ 1  0  0]
[ 1 -1  1]
[ 0  0  1], 2: [ 1  0  0]
[ 0  1  0]
[ 1  1 -1]}
sage: W = WeylGroup(['F',4])
```

```
sage: [s1,s2,s3,s4] = W.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: s4^2 == W.one()
True
sage: type(w) == W.element_class
True
```

unit()

Returns the unit element of the Weyl group

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

5.1.240 Rooted (Unordered) Trees

AUTHORS:

- Florent Hivert (2011): initial version

class sage.combinat.rooted_tree.**LabelledRootedTree**(*parent*, *children*, *label=None*, *check=True*)

Bases: sage.combinat.abstract_tree.AbstractLabelledClonableTree, sage.combinat.rooted_tree.RootedTree

Labelled rooted trees.

A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The *labelled rooted trees* are an inductive datatype defined as follows: A labelled rooted tree is a multiset of labelled rooted trees, endowed with a label (which can be any object, including `None`). The trees that belong to this multiset are said to be the *children* of the tree. (Notice that the labels of these children may and may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the only information it carries is its label) is said to be a *leaf*.

Every labelled rooted tree gives rise to an unlabelled rooted tree (`RootedTree`) by forgetting the labels. (This is implemented as a conversion.)

INPUT:

- `children` – a list or tuple or more generally any iterable of trees or objects convertible to trees
- `label` – any hashable Sage object (default is `None`)

EXAMPLES:

```
sage: x = LabelledRootedTree([], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
```

```
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[],[[], []]], label = 3)
3[None[], None[None[], None[]]]
```

Children are reordered using the value of the `sort_key()` method:

```
sage: y = LabelledRootedTree([], label = 5); y
5[]
sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: yxy2 = LabelledRootedTree((y, x, y), label = 2); yxy2
2[3[], 5[], 5[]]
sage: xyy2 == yxy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as `None`):

```
sage: yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
sage: LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

TESTS:

```
sage: xyy2._get_list() == yxy2._get_list()
True
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled rooted tree `self`.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

Note: The tree `self` must be normalized before calling this method (see `normalize()`). This doesn't matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note: This method overrides `RootedTree.sort_key()` and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `RootedOrderedTree`; under some circumstances they could inherit it from another superclass instead of from `RootedTree`, which would cause the method to forget the labelling. See the docstrings of `RootedTree.sort_key()` and `sage.combinat.ordered_tree.OrderedTree.sort_key()`.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
```

```
sage: x.sort_key()
((0, 3),)
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
sage: lb = RootedTrees()([[],[[], []]]).canonical_labelling()
sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

class sage.combinat.rooted_tree.**LabelledRootedTrees**

Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

This is a parent stub to serve as a factory class for labelled rooted trees.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.parent() is LRT
True
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LRT
True
```

Todo

Add the possibility to restrict the labels to a fixed set.

---

class sage.combinat.rooted_tree.**LabelledRootedTrees_all**(*category=None*)

Bases: sage.combinat.rooted_tree.LabelledRootedTrees

Class of all (unordered) labelled rooted trees.

See LabelledRootedTree for a definition.

Element

alias of LabelledRootedTree

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: LabelledRootedTrees().labelled_trees()
Labelled rooted trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to self.

EXAMPLES:

```
sage: LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.**RootedTree**(*parent=None*, *children=[ ]*, *check=True*)

Bases: sage.combinat.abstract_tree.AbstractClonableTree, sage.structure.list_clone.NormalizedClonableList

The class for unordered rooted trees.

The *unordered rooted trees* are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the *children* of the tree. The tree that has no children is called a *leaf*.

The *labelled rooted trees* (LabelledRootedTree) form a subclass of this class; they carry additional data.

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

EXAMPLES:

```
sage: RootedTree([])
[]
sage: RootedTree([[], [[]]])
[[], [[]]]
sage: RootedTree([[[]], []])
[[], [[]]]
sage: O = OrderedTree([[[]], []]); O
[[[]], []]
sage: RootedTree(O)  # this is O with the ordering forgotten
[[], [[]]]
```

One can also enter any small rooted tree ("small" meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the from_hexacode() function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[[]], [[]], [[], []]]
```

Note: Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as sage.structure.list_clone.NormalizedClonableList instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their sort_key() value. This is as good as storing them as multisets, since the sort_key() values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of RootedTree which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited sort_key() method will no longer distinguish different trees (and, as a consequence, equal trees will be regarded as distinct). Thus, you will have to override the method by one that does distinguish different trees.

---

graft_list(*other*)

Return the list of trees obtained by grafting other on self.

Here grafting means that one takes the disjoint union of self and other, chooses a node of self, and adds the root of other to the list of children of this node. The root of the resulting tree is the root of self. (This can be done for each node of self; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[[]]]
sage: l = y.graft_list(x); l
[[[], [], []], [[], [[]]], [[], [[]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

TESTS:

```
sage: x = RootedTrees(1)([])
sage: y = RootedTrees(3)([x, x])
sage: l = y.graft_list(x); l
[[[], [], []], [[], [[]]], [[], [[]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]

sage: x = RootedTree([[[], []], []])
sage: y = RootedTree([[], []])
sage: len(uniq(x.graft_list(y)))
4
```

graft_on_root(*other*)

Return the tree obtained by grafting `other` on the root of `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, and adds the root of `other` to the list of children of `self`. The root of the resulting tree is the root of `self`.

This is useful for free Nap algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_on_root(x)
[[]]
sage: y.graft_on_root(x)
[[], [], []]
sage: x.graft_on_root(y)
[[[], []]]
```

is_empty()

Return if `self` is the empty tree.

For rooted trees, this always returns `False`.

Note: This is not the same as `bool(t)`, which returns whether `t` has some child or not.

EXAMPLES:

```
sage: t = RootedTrees(4)([[],[[]]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1)([])
sage: t.is_empty()
```

```
False
sage: bool(t)
False
```

normalize()

Normalize `self`.

This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call `normalize` directly as it is called automatically upon creation and cloning or modification (by `NormalizedClonableList`).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the `sort_key()` method.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[],[[]]]) == RT([[[]],[]])  # indirect doctest
True
sage: rt1 = RT([[],[[]]])
sage: rt2 = RT([[[]],[]])
sage: rt1 is rt2
False
sage: rt1 == rt2
True
sage: rt1._get_list() == rt2._get_list()
True
```

sort_key()

Return a tuple of nonnegative integers encoding the rooted tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

Note: The tree `self` must be normalized before calling this method (see `normalize()`). This doesn't matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note: By default, this method does not encode any extra structure that `self` might have. If you have a subclass inheriting from `RootedTree` which allows for some extra structure, you need to override `sort_key()` in order to preserve this structure (for example, the `LabelledRootedTree` class does this in `LabelledRootedTree.sort_key()`). See the note in the docstring of `sage.combinat.ordered_tree.OrderedTree.sort_key()` for a pitfall.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[]]).sort_key()
(2, 0, 1, 0)
```

class sage.combinat.rooted_tree.**RootedTrees**
Bases: sage.structure.unique_representation.UniqueRepresentation, sage.structure.parent.Parent

Factory class for rooted trees.

INPUT:

- size – (optional) an integer

OUTPUT:

the set of all rooted trees (of the given size size if specified)

EXAMPLES:

```
sage: RootedTrees()
Rooted trees

sage: RootedTrees(2)
Rooted trees with 2 nodes
```

class sage.combinat.rooted_tree.**RootedTrees_all**
Bases: sage.sets.disjoint_union_enumerated_sets.DisjointUnionEnumeratedSets, sage.combinat.rooted_tree.RootedTrees

Class of all (unordered, unlabelled) rooted trees.

See RootedTree for a definition.

Element
alias of RootedTree

labelled_trees()
Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```
sage: lb = RootedTrees()([[],[[], []]]).canonical_labelling()
sage: lb
1[2[], 3[4[], 5[]]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.element_class'>
sage: lb.parent()
Labelled rooted trees
```

leaf()
Return a leaf tree with self as parent.

EXAMPLES:

```
sage: RootedTrees().leaf()
[]
```

unlabelled_trees()
Return the set of unlabelled trees associated to self.

EXAMPLES:

```
sage: RootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.**RootedTrees_size**(*n*)

Bases: sage.combinat.rooted_tree.RootedTrees

The enumerated set of rooted trees with a given number of nodes.

The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with a children is a plus the sum of the number of nodes of each of these children.

TESTS:

```
sage: from sage.combinat.rooted_tree import RootedTrees_size
sage: for i in range(1, 6): TestSuite(RootedTrees_size(i)).run()
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RootedTrees(1).cardinality()
1
sage: RootedTrees(3).cardinality()
2
```

check_element(*el*, *check=True*)

Check that a given tree actually belongs to `self`.

This just checks the number of vertices.

EXAMPLES:

```
sage: RT3 = RootedTrees(3)
sage: RT3([[],[]])      # indirect doctest
[[], []]
sage: RT3([[],[],[]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

element_class()

TESTS:

```
sage: S = RootedTrees(3)
sage: S.element_class
<class 'sage.combinat.rooted_tree.RootedTrees_all_with_category.element_class'>
sage: S.first().__class__ == RootedTrees().first().__class__
True
```

sage.combinat.rooted_tree.**number_of_rooted_trees**(*n*)

Return the number of rooted trees with n nodes.

Compute the number $a(n)$ of rooted trees with n nodes using the recursive formula ([SL000081]):

$$a(n+1) = \frac{1}{n}\sum_{k=1}^{n}\left(\sum_{d|k} d a(d)\right) a(n-k+1)$$

EXAMPLES:

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

5.1.241 Robinson-Schensted-Knuth correspondence

AUTHORS:

- Travis Scrimshaw (2012-12-07): Initial version

EXAMPLES:

We can perform RSK and the inverse on a variety of objects:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp)
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: m = RSK_inverse(p, q, 'matrix'); m
[0 1]
[1 0]
[0 2]
sage: RSK(m)
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
```

TESTS:

Check that it is a correspondence between all types of input and the input is preserved:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: gp = RSK_inverse(t1, t2); gp
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: w = RSK_inverse(t1, t2, 'word'); w
word: 14532
sage: m = RSK_inverse(t1, t2, 'matrix'); m
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: p = RSK_inverse(t1, t2, 'permutation'); p
[1, 4, 5, 3, 2]
sage: t1
[[1, 2, 5], [3], [4]]
sage: t2
[[1, 2, 3], [4], [5]]
sage: RSK(*gp) == [t1, t2]
True
sage: RSK(w) == [t1, t2]
True
sage: RSK(m) == [t1, t2]
True
sage: RSK(p) == [t1, t2]
True
```

```
sage: gp
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: w
word: 14532
sage: m
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: p
[1, 4, 5, 3, 2]
```

sage.combinat.rsk.**RSK**(*obj1=None*, *obj2=None*, *insertion='RSK'*, *check_standard=False*, ***options*)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i-th step inserts the number k_i into the i-th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i-th row, then k_i is simply appended to the row and the algorithm terminates at this point.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p, and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as "Construction A".

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top line to be $(1, 2, \ldots, n)$ where n is the length of w.

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion. If the input is a reduced word of a permutation (i.e., an element of a type-A Coxeter group), one can set `insertion` to `'EG'`, which gives Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that if k_i and $k_i + 1$ both exist in row i, we *only* set $k_{i+1} = k_i + 1$ and continue.

One can also perform a "Hecke RSK algorithm", defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns). The algorithm proceeds similarly to the classical RSK algorithm. However, it is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top line $(1, 2, \ldots, n)$ (or, at least, has its top line strictly increasing). The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \ldots, (P_\ell, Q_\ell)$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t$, $x = k_t$, $P = P_t$ and $Q = Q_t$. We are going

to insert x into the increasing tableau P and update the set-valued "recording tableau" Q accordingly. As in the classical RSK algorithm, we first insert x into row 1 of P, then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P. If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P. If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q, and fill it with the one-element set $\{i\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R, and add i to the entry of Q in this box (this entry is a set, since Q is a set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

INPUT:

- `obj1, obj2` – Can be one of the following:
  - A word in an ordered alphabet
  - An integer matrix
  - Two lists of equal length representing a generalized permutation
  - Any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists.
- `insertion` – (Default: `'RSK'`) The following types of insertion are currently supported:
  - `'RSK'` – Robinson-Schensted-Knuth
  - `'EG'` – Edelman-Greene (only for reduced words of permutations/elements of a type-A Coxeter group)
  - `'hecke'` – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing)
- `check_standard` – (Default: `False`) Check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

If we only give one line, we treat the top line as being $(1, 2, \ldots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

With a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

If we give it a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There are also variations of the insertion algorithm in RSK. Here we consider Edelman-Greene insertion:

```
sage: RSK([2,1,2,3,2], insertion='EG')
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
```

We reproduce figure 6.4 in [EG1987]:

```
sage: RSK([2,3,2,1,2,3], insertion='EG')
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Hecke insertion is also supported. We construct Example 2.1 in Arxiv 0801.1319v2:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: RSK(w, insertion='hecke')
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python $\star$ on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

TESTS:

Empty objects:

```
sage: RSK(Permutation([]))
[[], []]
sage: RSK(Word([]))
[[], []]
sage: RSK(matrix([[]]))
[[], []]
sage: RSK([], [])
[[], []]
sage: RSK([[]])
[[], []]
sage: RSK(Word([]), insertion='EG')
[[], []]
sage: RSK(Word([]), insertion='hecke')
[[], []]
```

sage.combinat.rsk.**RSK_inverse**(*p*, *q*, *output='array'*, *insertion='RSK'*)

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the

Robinson-Schensted-Knuth algorithm.

For more information on the bijection, see `RSK()`.

INPUT:

- `p`, `q` – Two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (Default: `'array'`) if `q` is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)
  - `'matrix'` – as an integer matrix

  and if `q` is standard, we can have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation
- `insertion` – (Default: `RSK`) The insertion algorithm used in the bijection. Currently the following are supported:
  - `'RSK'` – Robinson-Schensted-Knuth insertion
  - `'EG'` – Edelman-Greene insertion
  - `'hecke'` – Hecke insertion

Note: In the case of Hecke insertion, the input variable `q` should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both `p` and `q` are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Edelman-Greene insertion:

```
sage: pq = RSK([2,1,2,3,2], insertion='EG'); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion='EG')
[2, 1, 2, 3, 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: pq = RSK(w, insertion='hecke')
sage: RSK_inverse(*pq, insertion='hecke', output='list')
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
```

Note: The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

TESTS:

From empty tableaux:

```
sage: RSK_inverse(Tableau([]), Tableau([]))
[[], []]
```

Check that `RSK_inverse()` is the inverse of `RSK()` on the different types of inputs/outputs:

```
sage: f = lambda p: RSK_inverse(*RSK(p), output='permutation')
sage: all(p == f(p) for n in range(7) for p in Permutations(n))
True
sage: all(RSK_inverse(*RSK(w), output='word') == w for n in range(4) for w in Words(5, n))
True
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: M = IntegerMatrices([1,2,2,1], [3,1,1,1])
sage: all(RSK_inverse(*RSK(m), output='matrix') == m for m in M)
True

sage: n = ZZ.random_element(200)
sage: p = Permutations(n).random_element()
sage: is_fine = True if p == f(p) else p ; is_fine
True
```

Same for Edelman-Greene (but we are checking only the reduced words that can be obtained using the `reduced_word()` method from permutations):

```
sage: g = lambda w: RSK_inverse(*RSK(w, insertion='EG'), insertion='EG', output='permutation')
sage: all(p.reduced_word() == g(p.reduced_word()) for n in range(7) for p in Permutations(n))
True

sage: n = ZZ.random_element(200)
sage: p = Permutations(n).random_element()
sage: is_fine = True if p == f(p) else p ; is_fine
True
```

Both tableaux must be of the same shape:

```
sage: RSK_inverse(Tableau([[1,2,3]]), Tableau([[1,2]]))
Traceback (most recent call last):
...
ValueError: p(=[[1, 2, 3]]) and q(=[[1, 2]]) must have the same shape
```

sage.combinat.rsk.**hecke_insertion**(*obj1*, *obj2=None*)

Return the Hecke insertion of the pair `[obj1, obj2]`.

See also:

`RSK()`

EXAMPLES:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: RSK(w, insertion='hecke')
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
```

sage.combinat.rsk.**hecke_insertion_reverse**(*p*, *q*, *output='array'*)

Return the reverse Hecke insertion of `(p, q)`.

See also:

`RSK_inverse()`

EXAMPLES:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P,Q = RSK(w, insertion='hecke')
sage: wp = RSK_inverse(P, Q, insertion='hecke', output='list'); wp
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: wp == w
True
```

sage.combinat.rsk.**robinson_schensted_knuth**(*obj1=None*, *obj2=None*, *insertion='RSK'*, *check_standard=False*, ***options*)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i-th step inserts the number k_i into the i-th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i-th row, then k_i is simply appended to the row and the algorithm terminates at this point.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p, and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as "Construction A".

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top line to be $(1, 2, \ldots, n)$ where n is the length of w.

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion. If the input is a reduced word of a permutation (i.e., an element of a type-A Coxeter group), one can set `insertion` to `'EG'`, which gives Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that if k_i and $k_i + 1$ both exist in row i, we *only* set $k_{i+1} = k_i + 1$ and continue.

One can also perform a "Hecke RSK algorithm", defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns). The algorithm proceeds similarly to the classical RSK algorithm. However, it is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top line $(1, 2, \ldots, n)$ (or, at least, has its top line strictly increasing). The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \ldots, (P_\ell, Q_\ell)$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t$, $x = k_t$, $P = P_t$ and $Q = Q_t$. We are going to insert x into the increasing tableau P and update the set-valued "recording tableau" Q accordingly. As in the classical RSK algorithm, we first insert x into row 1 of P, then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P. If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P. If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q, and fill it with the one-element set $\{i\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R, and add i to the entry of Q in this box (this entry is a set, since Q is a set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

INPUT:

- `obj1, obj2` – Can be one of the following:
  - –A word in an ordered alphabet
  - –An integer matrix
  - –Two lists of equal length representing a generalized permutation

– Any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists.

- `insertion` – (Default: `'RSK'`) The following types of insertion are currently supported:
  - `'RSK'` – Robinson-Schensted-Knuth
  - `'EG'` – Edelman-Greene (only for reduced words of permutations/elements of a type-A Coxeter group)
  - `'hecke'` – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing)
- `check_standard` – (Default: `False`) Check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

If we only give one line, we treat the top line as being $(1, 2, \ldots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

With a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

If we give it a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There are also variations of the insertion algorithm in RSK. Here we consider Edelman-Greene insertion:

```
sage: RSK([2,1,2,3,2], insertion='EG')
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
```

We reproduce figure 6.4 in [EG1987]:

```
sage: RSK([2,3,2,1,2,3], insertion='EG')
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Hecke insertion is also supported. We construct Example 2.1 in Arxiv 0801.1319v2:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: RSK(w, insertion='hecke')
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
```

```
[(6,)],
[(8, 10)]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python $\star$ on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

TESTS:

Empty objects:

```
sage: RSK(Permutation([]))
[[], []]
sage: RSK(Word([]))
[[], []]
sage: RSK(matrix([[]]))
[[], []]
sage: RSK([], [])
[[], []]
sage: RSK([[]])
[[], []]
sage: RSK(Word([]), insertion='EG')
[[], []]
sage: RSK(Word([]), insertion='hecke')
[[], []]
```

sage.combinat.rsk.**robinson_schensted_knuth_inverse**(*p*, *q*, *output='array'*, *insertion='RSK'*)

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth algorithm.

For more information on the bijection, see `RSK()`.

INPUT:

- `p`, `q` – Two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (Default: `'array'`) if `q` is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)
  - `'matrix'` – as an integer matrix

  and if `q` is standard, we can have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation
- `insertion` – (Default: `RSK`) The insertion algorithm used in the bijection. Currently the following are supported:
  - `'RSK'` – Robinson-Schensted-Knuth insertion

– 'EG' – Edelman-Greene insertion

– 'hecke' – Hecke insertion

Note: In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Edelman-Greene insertion:

```
sage: pq = RSK([2,1,2,3,2], insertion='EG'); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion='EG')
[2, 1, 2, 3, 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: pq = RSK(w, insertion='hecke')
```

```
sage: RSK_inverse(*pq, insertion='hecke', output='list')
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
```

Note: The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

TESTS:

From empty tableaux:

```
sage: RSK_inverse(Tableau([]), Tableau([]))
[[], []]
```

Check that `RSK_inverse()` is the inverse of `RSK()` on the different types of inputs/outputs:

```
sage: f = lambda p: RSK_inverse(*RSK(p), output='permutation')
sage: all(p == f(p) for n in range(7) for p in Permutations(n))
True
sage: all(RSK_inverse(*RSK(w), output='word') == w for n in range(4) for w in Words(5, n))
True
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: M = IntegerMatrices([1,2,2,1], [3,1,1,1])
sage: all(RSK_inverse(*RSK(m), output='matrix') == m for m in M)
True

sage: n = ZZ.random_element(200)
sage: p = Permutations(n).random_element()
sage: is_fine = True if p == f(p) else p ; is_fine
True
```

Same for Edelman-Greene (but we are checking only the reduced words that can be obtained using the `reduced_word()` method from permutations):

```
sage: g = lambda w: RSK_inverse(*RSK(w, insertion='EG'), insertion='EG', output='permutation')
sage: all(p.reduced_word() == g(p.reduced_word()) for n in range(7) for p in Permutations(n))
True

sage: n = ZZ.random_element(200)
sage: p = Permutations(n).random_element()
sage: is_fine = True if p == f(p) else p ; is_fine
True
```

Both tableaux must be of the same shape:

```
sage: RSK_inverse(Tableau([[1,2,3]]), Tableau([[1,2]]))
Traceback (most recent call last):
...
ValueError: p(=[[1, 2, 3]]) and q(=[[1, 2]]) must have the same shape
```

`sage.combinat.rsk.`**`to_matrix`**`(t, b)`

Return the integer matrix corresponding to a two-line array.

INPUT:

- `t` – The top line of the array
- `b` – The bottom line of the array

OUTPUT:

An $m \times n$-matrix (where m and n are the maximum entries in t and b respectively) whose (i, j)-th entry, for any i and j, is the number of all positions k satisfying $t_k = i$ and $b_k = j$.

EXAMPLES:

```
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

5.1.242 Schubert Polynomials

sage.combinat.schubert_polynomial.**SchubertPolynomialRing**(*R*)

Returns the Schubert polynomial ring over R on the X basis.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
sage: X(1)
X[1]
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
sage: X([2,1,3])*X([2,1,3])
X[3, 1, 2]
sage: X([2,1,3])+X([3,1,2,4])
X[2, 1] + X[3, 1, 2]
sage: a = X([2,1,3])+X([3,1,2,4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

class sage.combinat.schubert_polynomial.**SchubertPolynomialRing_xbasis**(*R*)

Bases: sage.combinat.combinatorial_algebra.CombinatorialAlgebra

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True
```

Element

alias of SchubertPolynomial_class

class sage.combinat.schubert_polynomial.**SchubertPolynomial_class**(*M*, *x*)

Bases: sage.combinat.free_module.CombinatorialFreeModuleElement

Create a combinatorial module element. This should never be called directly, but only through the parent combinatorial free module's __call__() method.

TESTS:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']; f
B['a'] + 3*B['c']
sage: f == loads(dumps(f))
True
```

divided_difference(*i*)

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
```

expand()

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: map(lambda x: x.expand(), [X(p) for p in Permutations(3)])
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

TESTS:

Calling .expand() should always return an element of an MPolynomialRing

```
sage: X = SchubertPolynomialRing(ZZ)
sage: f = X([1]); f
X[1]
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
sage: f.expand()
1
sage: f = X([1,2])
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
sage: f = X([1,3,2,4])
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
```

multiply_variable(*i*)

Returns the Schubert polynomial obtained by multiplying self by the variable x_i.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]
```

scalar_product(*x*)

Returns the standard scalar product of self and x.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5, 7]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 + 3*x0*x1*x2*x3
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 + 3*x0*x1*x2*x3
```

sage.combinat.schubert_polynomial.**is_SchubertPolynomial**(*x*)
Returns True if x is a Schubert polynomial and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.schubert_polynomial import is_SchubertPolynomial
sage: X = SchubertPolynomialRing(ZZ)
sage: a = 1
sage: is_SchubertPolynomial(a)
False
sage: b = X(1)
sage: is_SchubertPolynomial(b)
True
sage: c = X([2,1,3])
sage: is_SchubertPolynomial(c)
True
```

5.1.243 Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through `SetPartition`.

class sage.combinat.set_partition.**SetPartition**(*parent*, *s*)
Bases: sage.structure.list_clone.ClonableArray

A partition of a set.

A set partition p of a set S is a partition of S into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of set partitions of n is called the n-th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of n. The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation i related to j if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the *length* of a set partition $A = \{A_1, \ldots, A_k\}$ is the number of parts of A and is denoted by $|A| := k$. The *size* of A is the cardinality of S. We will also sometimes use the notation $[n] := \{1, 2, \ldots, n\}$.

EXAMPLES:

There are 5 set partitions of the set $\{1, 2, 3\}$:

```
sage: SetPartitions(3).cardinality()
5
```

Here is the list of them:

```
sage: SetPartitions(3).list()
[{{1, 2, 3}},
 {{1}, {2, 3}},
 {{1, 3}, {2}},
 {{1, 2}, {3}},
 {{1}, {2}, {3}}]
```

There are 6 set partitions of $\{1, 2, 3, 4\}$ whose underlying partition is $[2, 1, 1]$:

```
sage: SetPartitions(4, [2,1,1]).list()
[{{1}, {2}, {3, 4}},
 {{1}, {2, 4}, {3}},
 {{1}, {2, 3}, {4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}}]
```

Since trac ticket #14140, we can create a set partition directly by `SetPartition`, which creates the base set by taking the union of the parts passed in:

```
sage: s = SetPartition([[1,3],[2,4]]); s
{{1, 3}, {2, 4}}
sage: s.parent()
Set partitions
```

apply_permutation(*p*)

Apply `p` to the underlying set of `self`.

INPUT:

- `p` – A permutation

EXAMPLES:

```
sage: x = SetPartition([[1,2], [3,5,4]])
sage: p = Permutation([2,1,4,5,3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3,2,1,5,4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}
```

arcs()

Return `self` as a list of arcs.

Consider a set partition $X = \{X_1, X_2, \ldots, X_n\}$, then the arcs are the pairs $i - j$ such that $i, j \in X_k$ for some k.

EXAMPLES:

```
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1,3,6,7],[2,5],[4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

base_set()

Return the base set of `self`, which is the union of all parts of `self`.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1,2,3,4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}
```

base_set_cardinality()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

cardinality()

Returns the len of `self`

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1,2,3]))
3
```

check()

Check that we are a valid ordered set partition.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()
```

coarsenings()

Return a list of coarsenings of `self`.

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[{{1, 2, 3, 4}},
 {{1}, {2, 3, 4}},
 {{1, 3}, {2, 4}},
 {{1, 2, 4}, {3}},
 {{1}, {2, 4}, {3}}]
```

```
sage: SetPartition([]).coarsenings()
[{}]
```

inf(*other*)

The product of the set partitions `self` and `other`.
